[T]hat he felt that there was no need for patients to stop using the commercial concentrates because at present there was no proof that the commercial concentrates were the cause of AIDS .... After discussion it was agreed that patients should not be encouraged to go over to cryoprecipitate for home therapy but should continue to receive the NHS or commercial concentrates in their usual way.<sup>119</sup>

### ***Reaction to a World Health Organization Meeting on AIDS in November 1983***

**12.75** The World Health Organization (WHO) met in Geneva between 22 and 25 November 1983 to discuss AIDS. The draft report of the meeting contained a section on the prevention and control of AIDS. In relation to blood and blood products, it stated:

AIDS cases have infrequently occurred in both hemophiliacs receiving clotting factor concentrates and in recipients of blood and blood component transfusions who do not have other apparent risk factors. Approaches to reducing the possibility of spreading AIDS by blood and blood products include: ... avoiding non-essential use of blood and blood products ... and preparing and using blood and blood products in such a way as to reduce the risk of transmitting AIDS.<sup>120</sup>

**12.76** The topic was developed in the paper:

Immunoglobulin and albumin prepared by generally accepted methods have not been implicated in AIDS and are considered safe. Coagulation factor concentrates, however, have been implicated in cases of AIDS. Although additional inactivation methods have recently been developed, it will not be possible to fully establish their effectiveness until the agent of AIDS is discovered.<sup>121</sup>

<sup>117</sup> See [SNF.001.0948]. This is labelled Appendix C. AIDS is mentioned in Appendix C(i).

<sup>118</sup> Minutes of the 14th meeting of UK Haemophilia Centre Directors held on Monday 17 October 1983 SNB.001.7517]

<sup>119</sup> Ibid [SNB.001.7517] at 7526. (Emphasis in original)

<sup>120</sup> 'Acquired Immunodeficiency Syndrome, an assessment of the present situation in the world'; draft report dated 12 December 1983 [SNF.001.2575] at 2592

<sup>121</sup> Ibid [SNF.001.2575] at 2594

**12.77** The association of factor concentrates with AIDS risk was acknowledged and unchallenged, so far as the draft report discloses, although continued use of concentrates was clearly envisaged. The alternative methods available for reducing risk were: reducing pool sizes; adopting process technology aimed at reducing contamination risks; and adopting specific donor/recipient practice, especially in the case of those newly diagnosed with haemophilia and requiring only infrequent therapy.

**12.78** On 5 December 1983, Dr McClelland, Director of the South East Scotland Blood Transfusion Service, prepared an initial report on the conference, for the Scottish RTDs' Meeting of 8 December.<sup>122</sup> He noted that the WHO meeting was chaired by Walter Dowdle and was heavily influenced by him, Dr Curran and Dr Francis, all three from the CDC. The association of factor concentrates with AIDS appeared to Dr McClelland, at the time, to have been exaggerated by them. He reported that the NIH had issued practice directions for follow-up of recipients of blood and blood products in the USA.

**12.79** In his report, Dr McClelland commented on steps that might improve safety for individual recipients of therapy, such as the use of small pool concentrates and batch dedication, in particular for those who were newly diagnosed and required only infrequent therapy. The evidence adduced at the conference was primarily related to experience in the USA. Dr McClelland's observations as a Transfusion Director indicate that there was still not unqualified acceptance of the infective agent theory in the UK by the end of 1983. Publications at the end of that year appear to confirm this.

#### *The requirement for a very high standard of proof*

**12.80** In an editorial published in the *British Medical Journal (BMJ)* of 10 December 1983, Dr Peter Jones, Newcastle Haemophilia Centre, reflected one extreme in the developing views among haemophilia clinicians of the risks associated with the therapeutic use of blood products.<sup>123</sup> The introductory paragraph set the tone:

People with haemophilia, their families, and their doctors feel threatened by the deluge of speculation about the possible side effects of treatment with blood products. Two topics hold their attention: the risk of contracting the acquired immunodeficiency syndrome (AIDS) and the risk of developing hepatitis and subsequent chronic liver disease.

**12.81** Characterising the risk of AIDS as a speculative possibility reflected the approach of Dr Kernoff at the beginning of the year and was not dissimilar to the DHSS view then prevailing. However, that view was becoming less sustainable in December, having regard to increasing knowledge of the characteristics of the disease and its prevalence.

**12.82** Dr Jones stated that the incidence of AIDS among haemophilia patients in the UK and USA was about 0.8 per thousand. He suggested as a possibility the idea that what had been seen in haemophilia patients was an entirely different disorder from that seen in homosexuals, caused by 'repeated antigenic challenge over many years' (the antigen overload theory) rather than by a transmissible agent.<sup>124</sup>

<sup>122</sup> Initial report for the Scottish Regional Transfusion Directors' meeting on 8 December 1983 [SNF.001.0552]

<sup>123</sup> Jones, 'Acquired immunodeficiency syndrome, hepatitis and haemophilia', *British Medical Journal*, 1983; 287:1737-1738 [LIT.001.0243].

<sup>124</sup> *Ibid* [LIT.001.0243] at 0244

**12.83** He posed the question: what risk is there of serious harm from haemophilia treatment? With limited exceptions, he considered that there was no justification for discontinuing the use of concentrates and that 'the risk of haemorrhage and its complications far outweighs the risk of developing AIDS'. Implicitly accepting the alternative aetiology – the transmissible agent theory – he said, in relation specifically to imported concentrates:

The commercial companies in the United States acted responsibly and quickly to exclude high risk donors, and similar action has now been taken in Britain

....<sup>125</sup>

**12.84** Dr Jones stated that, while there was anxiety about AIDS, the advice from Reference Centre Directors and the Haemophilia Society was to carry on with Factor VIII treatment.<sup>126</sup> He advised that, since no Factor VIII could be guaranteed AIDS-free, cryoprecipitate should be used to treat very young severely affected children and other options (DDAVP or porcine Factor VIII) should be used for older people with mild haemophilia or von Willebrand's disease and carriers of these disorders. The comments in the editorial reflected the view already advanced by Professor Bloom that AIDS required no significant change to therapy, save for particular groups of patients.

**12.85** Dr Jones' views were reported in *The Guardian* on 9 December 1983.<sup>127</sup> There was a further comment by Andrew Veitch, medical correspondent, relating to the two cases of AIDS in haemophilia patients that had by then been confirmed.<sup>128</sup> Mr Veitch reported the two cases and noted that the affected patients were thought to have contracted the disease from contaminated supplies of Factor VIII imported from the USA. He referred to emerging data from Germany on infection within the homosexual community, confirming fears that AIDS had arrived in Europe from the USA two years earlier. He quoted Dr Jones' comment that alternatives to concentrates should be used to treat very young, severely-affected children and older people with mild forms of haemophilia. Overall, the article reflected views somewhat less sanguine than those expressed by Dr Jones.

**12.86** On the other hand, there was a constituency of opinion among haemophilia clinicians, represented by Dr Winter at this Inquiry, which took a more pessimistic view of the risks associated with concentrate therapy but often could not practically adapt clinical practice to reflect their opinions on risk. He thought that as information of an association between factor therapy and AIDS was published, the practical necessity of using imported products induced a state of denial in some haemophilia clinicians:

[I]f you like, the clinicians didn't want to believe any of this data, because we have just been through such a very major advancement in healthcare .... In America it was the same .... There were lots of political issues around that. So none of the related agencies wanted to know this. That's why ... I'm sure, this data took some time to really hit home.<sup>129</sup>

<sup>125</sup> Ibid [LIT.001.0243] at 0244

<sup>126</sup> Ibid [LIT.001.0243]

<sup>127</sup> *The Guardian* [SGF.001.0944]

<sup>128</sup> Quoted in Chapter 9, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 1*, paragraph 9.141

<sup>129</sup> Dr Winter – Day 16, pages 28–29. A similar view was expressed by Professor Lever – Day 26, page 111. Professor Ludlam, who himself appears to have supported the antigen overload theory longer than many others, agreed that Dr Aledort found it particularly difficult to accept the possibility of a viral aetiology, even in the face of mounting evidence supporting that theory. Day 18, page 115

**12.87** However, as noted above, he also commented that many clinicians, even if they did accept the transmissible agent theory, thought that they could not change practice, given the benefits of factor concentrate therapy.<sup>130</sup> There were fundamental practical issues relating to the choice of therapeutic product for haemophilia treatment.

**12.88** There is no basis for a view that clinicians were deliberately suppressing or ignoring data on transmission in commenting on the use of concentrate therapy. It appears, rather, that those who promoted the continuing use of imported Factor VIII could not accept the conclusions resulting from those data. The problem was possibly that noted in relation to the workshop in January 1983 in Atlanta: too high a standard of proof was set. Full scientific proof according to accepted norms was impossible.<sup>131</sup>

**12.89** The official view of the cause of AIDS, as expressed by DHSS Ministers and officials throughout 1983 and into 1984, was essentially a negative view, that there was 'no conclusive proof' or 'no conclusive evidence' that AIDS was transmitted through blood products. That is discussed in Chapter 9, *Knowledge of the Geographic Spread and Prevalence of HIV/AIDS 1*, paragraphs 9.108–9.123. So far as it is possible to understand the published statements made at the time, they are consistent with what Professor Hann agreed was a requirement for a very high standard of proof.<sup>132</sup> Such a high standard was not met by a contemporaneous observation in a DoH publication that AIDS was 'almost certainly' transmissible by transfusion of blood and blood products.<sup>133</sup> The official government view at the end of the year was expressed in a letter dated 13 December 1983 written by Lord Glenarthur to John Maples MP, who had enquired about the government's assessment in light of recent press reports. It stated that the cause of AIDS was as yet unknown and there was no conclusive proof that the disease had been transmitted by US blood products. The practical situation was set out:

[T]he Government is committed to making this country self-sufficient in blood products .... Meanwhile, in the absence of a satisfactory alternative, we shall be dependent upon imports from the USA for an adequate supply of Factor VIII.<sup>134</sup>

**12.90** Professor Lever was asked to comment, with the benefit of hindsight, on the point at which there required to be a reassessment of the risk/benefit balance involved in the use of therapeutic products.<sup>135</sup> In summary, he pointed to two factors of importance as triggers of reassessment: evidence of immunosuppression associated with therapy and evidence of death from immunosuppression.<sup>136</sup> As far as the first of those is concerned, a haemophilia patient in Cardiff had become ill with suspected AIDS by the beginning of May 1983. Profound immunosuppression in the east and west of Scotland patients had been established by the studies carried out in 1983. A fatal outcome after immunosuppression in haemophilia was known from the middle of September 1983. The scene was set for review of current therapy.

### *Views of the Haemophilia Society in early 1984*

**12.91** On 9 January 1984, the Blood Products Sub-committee of the Haemophilia Society produced a paper reviewing blood products supply and related issues in England and Wales.<sup>137</sup> While the Sub-committee is likely to have had expert help, the paper illustrates the response of one interested community to scientific developments at the time. On the topic of AIDS, the paper repeated the position that no infective agent had been identified for AIDS and that there was no reliable evidence that the disease was transmitted through blood products. However it commented that if AIDS was so transmitted:

[T]he 'Mail on Sunday' reasoning – that importation of American blood products should cease<sup>138</sup> – may prove to be an over-simplification, as AIDS could still be transmitted from the British donor population. Certainly the immunological abnormalities which may be associated with AIDS are observable in haemophiliacs not exposed to commercial concentrates [e.g. in Scotland and Australia].<sup>139</sup>

**12.92** After discussion, it concluded that:

[T]here are no grounds for favouring NHS Factor VIII over commercial materials in the respects we have in the past considered relevant. In addition, of course, the marginal factors of stability and more convenient presentation favour commercial material.<sup>140</sup>

**12.93** It is of interest that the second well-documented case of AIDS, that of a patient in Cardiff, does not appear to have been acknowledged at this point. The paper reflected a view, still held by at least some haemophilia clinicians at the time and in particular by the Society's advisers, that factor concentrate therapy for haemophilia patients should continue, including the use of imported products.

**12.94** As a practical matter, with the exception of Scotland (and Northern Ireland when supplied from Edinburgh), there was no reasonable prospect of avoiding the use of imported commercial products in the UK as a whole during the first five months of 1984 if factor concentrate therapy was to continue. The Blood Products Sub-committee paper of 9 January 1984 commented on the rising trend of demand from 1975–82,<sup>141</sup> which showed no sign of levelling off. The proportion of total usage represented by NHS products fluctuated over the period but the critical factor was the use of commercial products. Never less than 54%, in the last four years of the period use of commercial products was consistently over 60% and in 1982 reached 66.6%. At that stage production at BPL was near its target of 30 million units. The paper noted:

[W]e must be somewhat doubtful that NBTS could achieve the requirement, stated by the UK Haemophilia Centre Directors, of 100 million units by the middle of the present decade.<sup>142</sup>

<sup>137</sup> Haemophilia Society Report [DHF.001.5151] The paper refers in terms to 'the United Kingdom' but the context indicates that the data referred to were not UK data.

<sup>138</sup> See Chapter 9, *Knowledge of the Geographic Spread and Prevalence of HIV/AIDS 1*, paragraph 9.85

<sup>139</sup> Haemophilia Society Report [DHF.001.5151] at 5154. <sup>141</sup> *Ibid* [DHF.001.5151] at 5157

<sup>142</sup> *Ibid* [DHF.001.5151]

**12.95** The Haemophilia Society's own projection of demand – 145 million units in 1985 rising to 178 million units in 2000 – was much higher than the Haemophilia Directors' estimate. On any view, the inevitable inference drawn by the paper was that the 'UK' – by which the Society must have meant England and Wales – would have to rely on imported Factor VIII 'for a very long time'.<sup>143</sup> The situation in Scotland was quite different and is discussed below, beginning at paragraph 12.124.

**12.96** The paper set out arguments in favour of imported products, covering ethical and financial factors as well as risk of infection. At that stage, there appears to have been little apprehension among those responsible for the paper that the use of imported products carried a high level of risk.

**12.97** In relation to AIDS and blood products, it stated:

The AIDS scare has given us the opportunity, which we have not yet utilised, to campaign strongly for self-sufficiency in blood products. Given, however, that the original factors in our policy no longer apply or have reduced force, and that AIDS is still a great unknown, I submit that we should not undertake such a campaign. Now is not the time to ask that all our blood-product 'eggs' should be placed in one basket. Instead, without necessarily abandoning our long-term objectives, we should take Mr Asquith's advice 'Wait and see'. When more facts emerge about AIDS we would then be in a better position to press for whatever action these facts seem to demand.<sup>144</sup>

### *Developments in 1984: the impact of HTLV-III infection*

**12.98** As noted above, on 23 April 1984 Dr Robert Gallo and his team announced the discovery of HTLV-III.<sup>145</sup> The identification of the virus is more fully discussed in Chapter 29, *The Discovery of HIV and the Development of Screening Tests*. Although it appears that some commentators remained of the view that the AIDS in haemophilia patients might be caused, not by the virus announced by Gallo and his team (or, indeed, that announced by Montagnier a year earlier), but by some other mechanism (such as antigen overload) it is reasonably clear that most accepted that the HTLV-III discovery pointed very clearly towards the infective agent theory. Professors Weiss and Tedder had been working on a screening assay for several months, using French virus obtained from Luc Montagnier,<sup>146</sup> and a prototype assay was ready for laboratory application on 4 July 1984, allowing them to begin epidemiological studies.<sup>147</sup> It took several months to develop an HIV test kit for general use, as discussed in Chapter 30, *Screening of Donated Blood for HIV*. In the meantime, however, many haemophilia clinicians had begun to submit samples to Professor Tedder.

**12.99** As noted above, in the last three months of 1984 the reality of HTLV-III infection in a significant proportion of Haemophilia A patients was brought home to clinicians, and the wider scientific and medical community, when test results became available.<sup>148</sup>

<sup>143</sup> Ibid [DHF.001.5151] at 5152

(reprint) [SNB0049457] See also Chapter 29, *The Discovery of HIV and the Development of Screening Tests*, paragraphs 29.11–29.14.

<sup>146</sup> Day 48, page 6; Letter from Professor Weiss to the Inquiry on the development of HIV screening tests [PEN.017.1261] at 1263

<sup>147</sup> Professor Tedder – Day 49, pages 15–16

<sup>148</sup> See paragraph 12.25 for the effect of publication of the Cheingsong-Popov article on 1 September 1984.

By October 1984, many Haemophilia Directors, including Professor Ludlam, Dr Winter and Dr Kernoff, had already had samples tested by Professor Tedder. Professor Forbes had samples tested by Dr Gallo. Many, if not all, Directors knew that some of their patients were infected with HTLV-III. All but one of Dr Winter's patients, about 30 in total, were infected.<sup>149</sup>

**12.100** In a letter dated 23 October 1984, Dr Craske reported that it had been confirmed that a donor who had provided plasma used in the preparation of a batch of Factor VIII concentrate had been admitted to hospital with AIDS. The letter was concerned mainly with Dr Craske's interests as a public health doctor and discussed the need for follow-up.<sup>150</sup> He referred, however, to the likelihood that any patient who had received commercial Factor VIII since 1980 had possibly already been exposed to HTLV-III.<sup>151</sup>

**12.101** A meeting of the UK Haemophilia Reference Centre Directors was held on 10 December 1984, chaired by Professor Bloom.<sup>152</sup> He introduced the meeting by referring to recent events in Newcastle and Australia 'and the continuing work on HTLV III'. The most extensive record of discussions available indicates that this was a major strategic meeting.<sup>153</sup> 'Events in Newcastle' included the death of a haemophilia patient who had contracted AIDS.<sup>154</sup> Apart from a comment attributed to Dr Ludlam, the record does not disclose a report of the cases of infection in Glasgow and Edinburgh, though from subsequent events it appears that the position in Edinburgh at least must have been disclosed.<sup>155</sup> After extensive discussion of HTLV-III antibody tests and their significance, Professor Bloom's summary was that HTLV-III antibody-positive haemophilia patients should be considered a risk but that it could not be assumed that those who were apparently HTLV-III antibody-negative were not, in fact, infective.<sup>156</sup> That appears to have set the scene for a discussion of clinical implications.

**12.102** It was anticipated that by the end of December 1984 or very early in 1985, Scotland would be self-sufficient in heat-treated concentrate. However, discussion proceeded to the availability and use of heat-treated Factor VIII more generally. It was reported that there was not a sufficient supply of NHS heat-treated concentrate to meet demand. In some circumstances the alternative to avoiding non-heat-treated concentrate would be that there would be no treatment. Professor Bloom summarised a long discussion by commenting that it was difficult to avoid the argument that non-heat-treated concentrate constituted a risk.

**12.103** According to an alternative record of the meeting, after prolonged discussion it was agreed that children should be treated with cryoprecipitate or if necessary with heat-treated Factor VIII.<sup>157</sup> New haemophilia patients should be treated with heat-treated Factor VIII. It was not proven that heat-treatment inactivated HTLV-III; nevertheless Directors felt that they should use commercial heat-treated Factor VIII in preference

See Chapter 33, *An Investigation into the Systems in Place for Informing Patients about the Risks*, paragraphs 33.303–33.308: It appears that details of the meeting were leaked to a journalist from *The Yorkshire Post* and that this included the report of infection in Edinburgh haemophilia patients.

<sup>156</sup> Ibid [SNF.001.3850] at 3853

<sup>157</sup> Meeting of the Haemophilia Reference Centre Directors, 10 December 1984 [DHF.003.0898]

to commercial non-heat-treated Factor VIII. Dr Jones reported to the meeting that at Newcastle all concentrate used was heat-treated commercial product. There had been no other change in therapy apart from holding back on prophylaxis for children on home therapy.<sup>158</sup> The Reference Directors agreed that heat-treated product should be given to all patients, if freely available.<sup>159</sup> The commercial products on the market were reviewed.<sup>160</sup> Most agreed to use non-heat-treated product until heat-treated product was available from BPL, although Dr Jones refused to do so, stating that all of his patients would have 'safe' heat-treated Factor VIII.<sup>161</sup>

**12.104** It was anticipated that this guidance would cause severe financial problems for treatment centres in England since the newly introduced US commercial heat-treated Factor VIII concentrate was more expensive.<sup>162</sup>

**12.105** There followed a discussion of the need to control the arrangements for the use of unlicensed products as it was felt that the rules at that time allowed companies to exploit the named patient system. In discussion of the availability and use of heat-treated Factor VIII, Professor Cash, Medical Director of the SNBTS, urged that the financial consideration be looked at seriously. Notwithstanding the small number of patients involved, the cost of imported heat-treated factor products would be high.<sup>163</sup> The regulatory bodies would also need to consider applications for variation orders on existing licences and to determine whether the products were new formulations requiring new licence applications. Commercial companies were being asked to reapply for licences for heat-treated products.<sup>164</sup> The meeting was concerned about the social attitudes being adopted towards AIDS patients and haemophilia patients. The situation was becoming very emotive and common sense was giving way to panic amongst donors, patients and contact groups.<sup>165</sup> Guidelines on treatment were to be issued by Professor Bloom after the meeting.

**12.106** The transmission of infection by the infusion of PFC Factor VIII was established in October 1984 in Edinburgh and the east of Scotland and in or about October 1984 in Glasgow and the west of Scotland. The information shared on 10 December (as summarised in the letter of 14 December referred to below) reflected acceptance of the transmissible agent theory and its association with profound immuno-suppression. Three patients with haemophilia had developed AIDS and two had died. Accordingly, the meeting on 10 December marked a further important juncture in the assessment of appropriate therapy: immunosuppression in haemophilia and its potentially fatal consequences was now definitively associated with NHS product. There was, in the event, a comprehensive reassessment of policy for the treatment of coagulation disorder patients.

**12.107** On 14 December 1984, the UKHCDO produced an 'AIDS advisory document', in consultation with Drs Lane, Cash, Gunson, Mortimer, Tedder, Craske and others.<sup>166</sup> The background information provided included data on infection. In the USA, there had been

<sup>158</sup> Ibid [SNF.001.3850] at 3853

<sup>159</sup> Ibid [SNF.001.3850] at page 3853

<sup>160</sup> Ibid [SNF.001.3850] at page 3856

<sup>161</sup> Ibid [DHF.003.0898] at 0899. By this stage the Newcastle Centre had a very high prevalence of HTLV-III infection as well as a death from AIDS.

<sup>165</sup> Ibid [SNF.001.3850] at 3860

<sup>166</sup> UKHCDO, 'Aids Advisory Document' [SGF.001.2388]

over 6000 cases of AIDS including 52 haemophilia patients. It was said that in the UK there had been 102 cases of AIDS with three reported cases in haemophilia patients and doubtless other cases developing. The information provided on infectivity was:

Antibody positivity probably correlates with exposure to imported concentrates but there have been two notable recent episodes concerning U.K. concentrates.

Antibody tests indicate prior infection but do not imply immunity as antibodies may not be neutralising ....

Antibody positive persons should ... be considered at risk of transmitting or developing AIDS but antibody negativity does not exclude infectivity.<sup>167</sup>

**12.108** The document described the tests available. It proceeded to discuss the inactivation processes currently in use and the processes used in the production of specific concentrates. It set out the options, in 'probable decreasing order of safety from AIDS for Haemophilia A' as:

1. Heated U.K. concentrate (note: still NANB hepatitis risk)
2. Single donor cryo. or FFP
3. Heated imported conc. (note: still NANB hepatitis risk)
4. Unheated U.K. conc.
5. Unheated imported conc – almost certain to be contaminated

...

#### RECOMMENDATIONS

1. Concentrate is still needed; bleeding is the commonest cause of disability and death.
2. Use DDAVP in mild Haemophilia A and vWd if possible.
3. For Haemophilia A needing blood products
  - a. 'Virgin' Patients those not previously exposed to concentrate, and children, use cryo or heated NHS factor VIII (if available)
  - b. Severe and Moderate haemophiliacs previously treated with factor VIII use heat treated NHS factor VIII, if available or heat treated US commercial.
4. Haemophilia B
  - a. Mild Christmas Fresh frozen plasma if possible (otherwise NHS Factor IX.
  - b. 'Virgin' Patients and those not previously exposed to concentrate use fresh frozen plasma (or NHS factor IX concentrate if essential)
  - c. Severe and Moderate Christmas Disease previously exposed to factor IX concentrate continue to use NHS factor IX.

In individual patients there may need to be a choice. In general heated concentrate appears to be the recommendation of virologists consulted but individual Directors may wish to make up their own minds. This is particularly true of unheated NHS material. The evidence that heated U.S. factor VIII is safer than unheated NHS is debateable and some Directors may wish to continue

<sup>167</sup> Ibid [SGF.001.2388] at 2388

using unheated NHS material until all supplies are heated. This is valid for carefully selected patients but must be on individual decision based on the assumption that some batches of NHS materials will be contaminated with HTLVIII. The argument that HTLV III positive patients have already been infected and could receive unheated American material is probably scientifically true but this material would pose an additional risk to staff and families and its continued use would pose logistic problems.<sup>168</sup>

**12.109** In the case of haemophilia B, Professor Ludlam summed up the position in 1984:

I had a few patients with particularly moderate Haemophilia B. That was difficult. I think there was commercial heat-treated Factor IX of unproven safety from a donor pool that was likely to have many more HIV positive donors in it, versus [non-heat-treated] NHS clotting Factor IX. We knew at that stage in December 1984 that the prevalence of anti HTLV-III positivity in Haemophilia B was very much lower than in Haemophilia A, and we presumed that that was because the virus to a large extent was excluded in the manufacturing process, excluded from the final Factor IX product. So Factor IX was seen as a much safer product from the point of view of HTLV-III, even unheated. So the national recommendation was to continue to use unheated NHS Factor IX concentrate in those who had already been exposed to it and to use fresh-frozen plasma in patients who hadn't been exposed to it, if possible. If they had severe new patients with severe haemophilia, they might anyway have to be put on to the concentrate but to use UK concentrate. So it wasn't an entirely black and white issue. It was in a sense slightly easier to not use the heat-treated commercial because the epidemiology at that stage was that patients were much less likely to get infected with anti HTLV-III.<sup>169</sup>

## Clinical response to the emergence of AIDS: Scotland

### *The aetiology of AIDS: competing theories in Scotland*

**12.110** In common with both the USA and England and Wales, as discussed above, until at least June or July 1984 it remained a common view among commentators in Scotland, representing a broad spectrum of medical and scientific expertise, that the cause of AIDS was unknown and that it had not been established, or proved, that it resulted from transmission of a specific agent in blood products. Even after that date, a small number of commentators continued to resist the transmissible agent theory. In Scotland, as already noted, two separate studies in 1983 – led by Professor Ludlam in Edinburgh and the east of Scotland and by Professor Forbes in Glasgow and the west of Scotland – attempted to determine whether the phenomenon of immune abnormalities in haemophilia patients first noted in the USA in 1982 was also occurring in Scottish haemophilia patients.

### Edinburgh research

**12.111** Professor Ludlam explained that he was prompted to conduct his research following the publication of a letter in *The Lancet* by Dr Robert Gordon, NIH, dated 30 April 1983. The letter noted that, by March 1983, eleven cases of clinical AIDS in haemophilia patients had been reported to the CDC. It presented the two principal possible aetiologies

<sup>168</sup> Ibid [SGF.001.2388] at 2389–2390. (Emphasis in original.)

<sup>169</sup> Professor Ludlam – Day 44, pages 41–42

considered at the time: the transmissible agent theory and the immune overload theory. Dr Gordon concluded by suggesting that 'the alternative hypotheses might be distinguished through a study ... among similarly treated haemophiliacs in a geographical area to which AIDS has not yet been introduced'.<sup>170</sup> Professor Ludlam said:

I thought that we were studying individuals with haemophilia who were treated with blood products in what appeared to be an AIDS-free population, and therefore perhaps the results that I was beginning to gather might be able to address the question that Dr Gordon is posing.<sup>171</sup>

**12.112** He carried out his research in the spring of 1983 and found that many of his coagulation disorder patients who were otherwise feeling well had immune abnormalities very similar to those reported from homosexual men and haemophilia patients living in North America.<sup>172</sup> As he saw it, however, it was inappropriate in mid- to late-1983 to make an assumption that the AIDS in people with haemophilia was necessarily of similar aetiology to the AIDS in the other groups. It was known that, clinically, the spectrum of AIDS-related conditions differed to some extent as between the groups and so clinicians considered the possibility that they had arisen simultaneously, or nearly simultaneously, but were of different aetiologies.<sup>173</sup>

**12.113** Professor Ludlam's view in 1983 was that, while his patients had immune abnormalities similar to those reported in homosexual and other populations in the USA, they could not have been infected with an AIDS virus and that, at least in Edinburgh, haemophilia patients' immune disturbances were not due to an AIDS-causing agent.<sup>174</sup> In a letter to *The Lancet* dated 28 May 1983, reporting on his research, Professor Ludlam expressed confidence in the local blood supply and, subsequent to this, explicitly endorsed the 'antigen overload' hypothesis as a possible explanation for the immune irregularities he had observed in his haemophilia patients:

Since there are no known cases of AIDS in our blood donor population it seems likely that the immunosuppression observed in haemophiliacs ... results from infusion of foreign proteins or a ubiquitous virus rather than a specific AIDS virus in factor VIII concentrates.<sup>175</sup>

**12.114** In due course it emerged that there were three sub-sets among the patients with lymphocyte abnormalities in the study group: those with abnormal immune systems who were subsequently shown to be infected with HIV; those with abnormal immune systems who were not infected with HIV; and those with normal immune systems who were infected but in whom changes in the immune system had not yet begun.<sup>176</sup>

<sup>174</sup> Day 19, page 18; Day 19, page 21; Chapter 11, *HIV/AIDS Aetiology*, paragraph 11.85

<sup>175</sup> Ludlam, 'Disordered immune regulation in haemophiliacs not exposed to commercial Factor VIII', *The Lancet*, 28 May 1983 [LIT.001.0416]

<sup>176</sup> Day 19, pages 18–20. Ludlam, et al, 'Human T-Lymphotropic Virus Type III (HTLV-III) Infection in Seronegative Haemophiliacs After Transfusion of Factor VIII', *The Lancet*, 3 August 1985 [SNB.008.3434] at 3436

**12.115** Professor Ludlam noted that there was ‘much speculation’ as to the cause of the immune irregularities observed in haemophilia patients.<sup>177</sup> In oral evidence he noted that the immune system ‘has only a number of limited ways’ of responding to ‘provocation’ and that, therefore, there were ‘lots of possible reasons why you can get these immune changes’.<sup>178</sup> The possibilities considered were: (i) that immune disturbance could have been a previously undescribed feature of haemophilia; (ii) that chronic liver disease (and many haemophilia patients had contracted hepatitis viruses by transfusion) had caused changes in patients’ immune systems; (iii) that large amounts of proteins other than Factor VIII/IX present in blood products for the treatment of haemophilia had disordered patients’ immune systems (the antigen overload theory); and (iv) that the immune changes observed could have been caused by a putative AIDS virus (the transmissible agent theory).<sup>179</sup> He stated that, at the time, he and others tended to believe that the antigen overload theory was particularly convincing, although he did not dismiss the transmissible agent theory entirely:

Of the four principal causes for immune modulation in haemophiliacs there was general agreement that it was due, at least in part, to the extraneous non-factor VIII proteins in the concentrates. Some of the immune disturbances might in addition be due to the presence of a putative AIDS virus in some patients.<sup>180</sup>

**12.116** In oral evidence, he suggested that the results of his studies ‘cast doubt over the extent of infection with a putative virus in other patients with haemophilia elsewhere in the world. That was one of the inferences from this’.<sup>181</sup> Indeed, his research supporting the antigen overload theory was to receive international attention and form part of the evidence base for international debate around the aetiology of AIDS. At a joint meeting of the World Federation of Haemophilia and the International Society on Thrombosis and Haemostasis in June 1983, discussed above, the response of US delegates to the suggestion that commercial concentrates manufactured in North America might be ‘bad news’ (implying that they might be contaminated with an AIDS-causing virus) was ‘to cite Ludlam *et al*’ and cast doubt upon the data implicating commercial products. Dr Foster, who attended the meeting, thought at the time that there was in this ‘something of an attempt to suppress AIDS “hysteria”’ but that some of the arguments put forward ‘did appear to make some sense’.<sup>182</sup>

**12.117** In oral evidence, Professor Ludlam summarised the thinking behind the antigen overload theory:

I calculated ... that in an average lifespan, you gave out a kilogramme of protein intravenously in an average severe haemophiliac. We are not designed to accept proteins in that magnitude intravenously. So one possibility was that ... maybe haemophilia as a whole was sliding into AIDS because of all the concentrate we were using. Quite separate from HIV or a putative virus.<sup>183</sup>

<sup>177</sup> Prof Ludlam – Human Immunodeficiency Virus Infection in Haemophiliacs [PEN.015.0385] at 0401; Day 19, page 18

<sup>178</sup> Day 19, page 17

<sup>179</sup> Prof Ludlam – Human Immunodeficiency Virus Infection in Haemophiliacs [PEN.015.0385] at 0401–0405. In another statement on contemporaneous thoughts on the possible aetiology of AIDS, Professor Ludlam suggested, in addition to the aetiologies noted above, that it was briefly considered that a previously identified virus (such as the Hepatitis B virus) might have mutated to cause immunosuppression; that a virus (such as CMV or EBV) already known to cause immune suppression had become more ‘virulent’; and the use of recreational drugs (such as amyl nitrate).

<sup>183</sup> Day 18, page 150

## Glasgow research

**12.118** There was similar research in Glasgow, published in October 1983.<sup>184</sup> Professor Forbes' research group also found an association between the administration of large amounts of Factor VIII concentrate and the immune process, which was suppressed in many patients and presumed by the research group to be caused by something in the concentrate they were given. He thought that there was a mystery, not resolved even now; as with Professor Ludlam's group, it was to transpire, when HIV testing became available, that not all of the haemophilia patients in his group with immune irregularities were HIV-positive at the time of the initial research. His comment was:

I think it was probably accurate to say that there were abnormalities but what they meant, we didn't know, and of course, some of it probably was that they were infected with the unknown virus, HIV. So we were looking for something but we didn't know what we were looking for at the time.<sup>185</sup>

**12.119** The report of this research suggested gradual diminution of the patients' ability to resist infections or neoplasms (tumours) as a possible consequence of repeated injection. As Professor Forbes recalled, he and his colleagues 'guessed it probably was some kind of virus that we had never encountered before'.<sup>186</sup>

## A spectrum of opinion

**12.120** In Scotland as internationally, then, from the initial reports of immune irregularities in various cohorts of patients, there was a spectrum of opinion as to the aetiology of AIDS. Shortly before his appointment at Yorkhill, Professor Hann attended the Second International Symposium of Infections in the Immunocompromised Host, held in Stirling in June 1982. Despite not originally being included amongst the topics for discussion, AIDS was 'the talk of the meeting', although discussion was characterised by 'extreme' puzzlement. Various aetiologies for the new and alarming condition were presented at that conference, including cytomegalovirus infection alongside hereditary factors and amyl nitrate use.<sup>187</sup> Professor Hann noted that the proceedings of the symposium made only passing reference to the possibility of transmission by blood and blood products<sup>188</sup> but, in oral evidence, said that 'it was thought most likely that there may have been a new agent, a new viral agent, but that may well not be the only cause'.<sup>189</sup> Although he adapted practice at Yorkhill upon his appointment, at least in part due to concerns about AIDS, this appears, at least in the earlier stages of the epidemic, to have been based on precaution rather than firm scientific evidence implicating blood and blood products:

My memory ... is that it was not plainly obvious at this time [early 1983], until later that year... and I would say the second half of that year ... that this was a blood product transmitted issue in haemophilia.<sup>190</sup>

<sup>184</sup> Froebel et al, 'Immunological abnormalities in haemophilia: Are they caused by American Factor VIII concentrate?' *British Medical Journal*, 1983; 287: 1091–1093 [LIT.001.0215] See Chapter 11, *HIV/AIDS Aetiology*, paragraphs 11.73–11.75

<sup>189</sup> Day 21, page 45

<sup>190</sup> Day 31, page 16

**12.121** According to Professor Forbes, he and his colleagues guessed that the observed immune irregularities in haemophilia patients were caused by a novel virus. For much of 1983, that remained a controversial view, however; there was, he noted, 'still a lot of doubt about it and many people didn't believe it was an infective agent'. It took time for proof of a viral aetiology to emerge and he thought that 'all this was speculation at the time'. He thought, however, that as 1983 progressed, a viral aetiology for AIDS in haemophilia patients 'rapidly' became clear and that, over the course of the year, 'most people' came to accept that AIDS was caused by transmission of an infective agent.<sup>191</sup>

**12.122** Professor Ludlam appears to have resisted the infective agent hypothesis longer than some others: neither increasing numbers of haemophilia patients exhibiting immune irregularities (in the USA, the UK and elsewhere) nor specific cases (such as 'the San Francisco child')<sup>192</sup> were, for him, 'clinching events' sufficient to prove to his satisfaction that AIDS was transmissible by blood products. Although he acknowledged the significance of these developments, he thought that the antigen overload hypothesis was 'still on the table' for much of 1983.<sup>193</sup> As early as July 1982, he had accepted that a viral aetiology 'had to be a possibility'.<sup>194</sup> In oral evidence, however, he agreed that for him it may have been as late as January 1984 that he fully accepted that the antigen overload hypothesis was 'increasingly less tenable'.<sup>195</sup> He agreed that, following the identification of LAV in May 1983, he continued to prefer the antigen overload theory. A further article on the Edinburgh research was published in June 1984, again showing a preference for the antigen overload theory. This was, however, around the same time as Gallo and colleagues announced the discovery of HTLV-III. Asked how he had reacted to the discovery of HTLV-III, which pointed clearly towards the transmissible agent theory as being correct, undermining his previously held conviction, Professor Ludlam replied:

I had no difficulty in accepting and it was very welcome news that a virus had been identified, absolutely.<sup>196</sup>

**12.123** In general, it appears that, as Dr Winter (and Professor Forbes) suggested, 1983 saw a 'gradation' of opinion and 'gradual acceptance that [AIDS] couldn't just be put down to immunological-based theories and that the epidemiology looked more and more like an infectious agent'. As noted above, even the discovery of HTLV-III was not sufficient for a minority of commentators to fully accept the infective agent hypothesis, although the discovery of HTLV-III was clearly the fundamental development in the aetiology debate for a great many interested parties.

### ***Confidence in domestic product and supply***

**12.124** Attitudes towards the choice of therapeutic materials for coagulation disorder patients in Scotland at this time appear to have reflected the confidence in NHS products and in the availability of supply of those domestically sourced products, particularly as compared with England and Wales. On 22 July 1983, the *Edinburgh Evening News* carried a report of an interview with Mr John Watt, Director of the Protein Fractionation Centre

<sup>191</sup> Day 17, page 97

<sup>192</sup> See Chapter 11, *AIDS Aetiology*, paragraphs 11.25–11.27

<sup>195</sup> Day 18, page 155

<sup>196</sup> Day 19, page 17

(PFC – the Scottish manufacturer of NHS blood products).<sup>197</sup> It was reported that Scotland was virtually self-sufficient in blood products and that only a small percentage came from the USA.

**12.125** The claim of virtual self-sufficiency was repeated in a letter to *The Scotsman* dated 14 July 1983, by Professor Ronald Girdwood, Chairman of the SNBTS. Contrasting the Scottish position with that in England, he wrote:

[T]he Scottish National Protein Fractionation Centre at Liberton ... is a very advanced non-commercial centre ....The staff are aware of the problems of the AIDS difficulties in the United States and have appropriately modified their processes here. Patients in Scotland should be reassured by the fact that, although the Elstree Centre has yet to be expanded, such development took place several years ago in Scotland and we are virtually self-sufficient.<sup>198</sup>

**12.126** Differences of opinion were to emerge as to whether these claims to self-sufficiency were accurate throughout Scotland and whether the assertion was correct that manufacturing processes had been ‘appropriately’ modified. Data on product use are discussed below. The comments clearly reflected attitudes at the time, however.

**12.127** As will be seen, there was some change in clinical practice as heat-treated commercial products came onto the market later in 1984. In the critical period between the spring of 1983 and the end of 1984, however, Scottish haemophilia clinicians were in the relatively privileged position of having available a more or less ample supply of domestically produced concentrates for therapy which, as indicated in Professor Ludlam’s letter to *The Lancet* quoted above, were considered to be free of the postulated AIDS-causing agent. Occasional use of imported products continued in some centres for a small number of patients with special clinical needs, for example where the patient could not tolerate the PFC product. That aside, Scotland was not confronted with the difficulties found by English practitioners, in having to use large quantities of imported concentrates because of a lack of supply of domestically sourced alternatives. Therefore, so far as Scottish practice is concerned, the issue, is whether use of PFC factor concentrates should have continued at all. The alternatives were those identified in England in Wales, or more amply in US practice: the use of cryoprecipitate or of DDAVP. In the first instance, however, it is appropriate to note the data on actual product use throughout the material time.

#### *Use of blood products in Scottish haemophilia therapy to 1984*

**12.128** On 21 January 1983, at a joint meeting of the Directors of the SNBTS and the Scottish Haemophilia Directors, Professor Cash referred to recent articles in the USA, and also in *The Observer* and *The Lancet*, about the problem of AIDS.<sup>199</sup> An extract from the CDC publication *Morbidity and Mortality Weekly Report (MMWR)* had been circulated with his paper. The SNBTS and the Haemophilia Directors were clearly aware of the situation developing in the USA. By then, however, there had already been movement in the choice of therapeutic products in those regions that had not previously used Scottish products exclusively.

<sup>199</sup> Minutes of joint meeting of the Directors of the SNBTS and the Haemophilia Directors on 21 January 1983 [SNB.001.5160] at 5166

## The Royal Infirmary of Edinburgh

**12.129** The numerical data for Edinburgh<sup>200</sup> show that in 1980 and 1981, following the appointment of Professor Ludlam as Haemophilia Director, there was an initial increase in usage overall, mainly of cryoprecipitate and PFC Factor VIII but with commercial product usage rising in significance as output from the PFC failed to keep up with growing demand. In 1982, small quantities of two commercial products, Koate and Factorate, were used, representing about one half of one per cent of total Factor VIII usage. Use of cryoprecipitate continued to fall from its peak in 1980 to the end of the period. In the most critical part of the period, 1980–84, commercial product use was a minor element of the total Factor VIII prescribed.

## Glasgow: Yorkhill and the Glasgow Royal Infirmary

**12.130** Within Glasgow, the GRI and Yorkhill operated independently, although Dr Willoughby, Haemophilia Director at Yorkhill, referred to Professor Forbes at the GRI for advice before Professor Hann's appointment in January 1983 and Professor Hann also 'worked very closely with the adult centre' at the GRI after his appointment.<sup>201</sup>

**12.131** Dr Willoughby had favoured commercial concentrates for the home treatment of children with coagulation disorders on the ground of ease of use. Upon taking up the post, Professor Hann 'inherited' some residual stock of imported products. As noted above, however, Professor Hann regarded NHS materials as both more cost-effective and safer<sup>202</sup> and use of commercial products fell very quickly and dramatically in 1983–84. Thereafter, products supplied by the PFC were used exclusively.<sup>203</sup>

**12.132** Professor Forbes was Director of the Regional Haemophilia Centre at the GRI from 1983–87. As noted in Chapter 21, *Haemophilia Therapy – Use of Blood Products*, his account of the use of therapeutic materials at the GRI Centre was not clear. As recorded,<sup>204</sup> commercial product use at the GRI was inconsistent and without obvious pattern. From a peak in 1979, it fell to a very low level in 1982, increased in 1983, and fell again to a more or less nominal amount in 1984. Overall, a wide range of products contributed to total use, particularly Koate, Factorate, Kryobulin, Hemofil VIII and Humanate, without any apparent structured sourcing policies.

## Other centres

**12.133** In the rest of Scotland, use of Factor VIII and Factor IX concentrates was almost exclusively of PFC products.<sup>205</sup> In these circumstances there was clearly no uniform policy relating to product selection in Scotland as a whole. Until the mid-1980s each haemophilia centre operated independently: the centres carried out more or less separate institutional roles.<sup>206</sup> As matters developed, however, there was coincidentally a broad similarity of practice among Haemophilia Directors. By the spring of 1983, clinical practice in the treatment of coagulation disorder patients, with factor concentrates, was largely limited to the use of PFC products.<sup>207</sup>

<sup>200</sup> See Chapter 21, *Haemophilia Therapy – Use of Blood Products*, Table 3 and Figure 8.

<sup>201</sup> Professor Hann's Witness Statement [PEN.012.0203]; Day 21, page 14; Day 31, page 63. Professor Hann explained that this cooperation was necessary for 'transitional care' as children at Yorkhill moved to the adult centre at the GRI.

<sup>203</sup> See Chapter 21, *Haemophilia Therapy – Use of Blood Products*, Table 4 and Figure 9

<sup>204</sup> See Chapter 21, *Haemophilia Therapy – Use of Blood Products*, Table 5 and Figure 10

<sup>205</sup> See Chapter 21, *Haemophilia Therapy – Use of Blood Products*, Tables 6, 7 and 8 and Figures 11, 12 and 13. Inverness used no commercial products at all from 1974 onwards.

<sup>206</sup> Professor Ludlam – Day 18, page 102

<sup>207</sup> See Chapter 21, *Haemophilia Therapy – Use of Blood Products*, Table 1 and Figures 5 and 6 for aggregate product usage in Scotland.

***The production and use of therapeutic materials in early 1984***

**12.134** The production and use of therapeutic materials was discussed at a joint meeting of the SNBTS Directors and the Haemophilia Directors, held on 2 February 1984. Professor Cash produced a paper setting out the background and indicating the views held at that time about the materials required.<sup>208</sup> Details of the amount of fresh plasma processed at the PFC for Factor VIII concentrates and the pattern of issue of concentrate were said to indicate that the production level was about right. Professor Cash said that trends over the previous five years indicated that the SNBTS production of Factor VIII concentrates might be exceeding clinical demand, in that current stocks at RTCs appeared to be increasing. It was agreed at the meeting that it was desirable to maintain the current production target and that existing stocks should be held for possible sudden demands on the service and to bridge the period when the PFC would be converting to a heat-treated product. It was noted that, if a surplus of PFC Factor VIII arose, other parts of the UK could be offered the product in preference to purchasing from other sources. No wastage was envisaged.

**12.135** It was recorded that the GRI was totally satisfied with the PFC product and had intimated that it was no longer necessary to purchase commercial alternatives. Dr Hann commented that he was prepared to dispose of the 30,000 units of commercial product he had 'inherited' at Yorkhill as it was going out of date. (From the numerical data outlined above, it also appears that Professor Hann had already dramatically reduced the use of these materials.) Professor Ludlam indicated that he needed a small stock of high purity Factor VIII, which would have to be imported from commercial suppliers for a very few patients. It was noted that in Glasgow and Edinburgh children were being treated with cryoprecipitate as the preferred material and that it was recognised that, bearing in mind reports from abroad, recipients of blood could 'also' be at risk.<sup>209</sup> Professor Ludlam said that cryoprecipitate was preferred in the treatment of children at that juncture because of the new danger of AIDS. Dr Hann concurred but noted that otherwise a policy seemed to be emerging to use less cryoprecipitate for Haemophilia A patients. It was agreed that a certain minimum amount of cryoprecipitate was required and Professor Cash pointed out that in emergencies Transfusion Directors could produce it themselves.<sup>210</sup> It was accepted that given domestic production it was not necessary in general to purchase commercial products from abroad unless, exceptionally, a superior product was available and clinically necessary.

**12.136** So far as Factor IX concentrates were concerned, it was noted that some Defix (a non-heat-treated SNBTS Factor IX concentrate) was still required and its availability would be retained. Subject to the provision of data which satisfied the Licensing Authority it was hoped to introduce Supernine (an improved SNBTS Factor IX concentrate)<sup>211</sup> in 1984–85, for routine use throughout the Scottish health service. These arrangements were seen as an interim step pending the development of a heat-treated product, details of which were set out in the paper.<sup>212</sup>

<sup>208</sup> Minutes of the joint meeting of the SNBTS Directors and the Haemophilia Directors held on 2 February 1984 [SNB.001.5252] at 5253

<sup>209</sup> Information about the use of commercial products is discussed, generally, in Chapter 21, *Haemophilia Therapy – Use of Blood Products*.

<sup>210</sup> Minutes of the joint meeting of the SNBTS Directors and the Haemophilia Directors held on 2 February 1984 [SNB.001.5252] at 5253

<sup>211</sup> Supernine had been developed in the hope of reducing hepatitis transmission. It was chemically treated, not heat-treated.

<sup>212</sup> Minutes of the joint meeting of the SNBTS Directors and the Haemophilia Directors held on 2 February 1984 [SNB.001.5252] at 5254

**12.137** Other strategies were discussed, including the possibility of 'batch dedication' of Factor VIII, designed to expose patients to the lowest number of batches of concentrate in order to reduce the risk of transmission of infection. This was a major review of clinical practice and of the demands that were created for therapeutic products. There was a preference for materials produced using plasma from locally donated (that is, Scottish) blood, with cryoprecipitate and other single-donor products identified as appropriate for limited groups of recipients, in line with current practice. It appears to be clear that extending the use of cryoprecipitate beyond those groups would have involved its use in the treatment of patients other than the vulnerable groups, such as children, who were already catered for by clinical practice. That apart, the policy that emerged clearly from the discussion at this stage in early 1984 was developed around the continuing use of concentrates produced from locally collected plasma.

**12.138** The purchase of commercial heat-treated products was not discussed at the joint meeting of the SNBTS Directors and the Haemophilia Directors held on 2 February 1984, so far as the minutes disclose.<sup>213</sup> By then, however, the use of commercial Factor VIII products in Scotland had almost ceased.<sup>214</sup> Use of cryoprecipitate had dwindled by 1983 to a very small percentage of total Factor VIII replacement therapy.<sup>215</sup> With the exception of patients requiring FEIBA<sup>216</sup> and a small number for whom commercial products were prescribed as a matter of clinical judgment, the product of choice in 1983 and 1984 was PFC Factor VIII concentrate. There was no general move towards imported heat-treated products until December 1984.

### *The development of heat-treated products*

**12.139** The development of heat-treated products had been in hand for some considerable time, however. Commercial heat-treated products were licensed by the FDA on various dates in and after March 1983 but in the case of most companies licences were granted during and after January 1984.<sup>217</sup> Alpha Therapeutics' product, Profilate HT, was licensed in February 1984. Because of concern over AIDS, Dr Winter and doctors from St Thomas' Hospital and the Royal Free Hospital, London, and from Sheffield approached Alpha in February for supplies of their heat-treated Factor VIII to be prescribed on a named patient basis (which under the Medicines Act 1968 allowed products to be prescribed without the need for a licence). They received some Alpha heat-treated product in May 1984 and used it on a selective basis until more ample supplies became available later in that year.<sup>218</sup>

**12.140** On 22 March 1983, Professor Forbes agreed to trial a new heat-treated Factor VIII product then being developed at the PFC.<sup>219</sup> However, it was to be December 1984 before the PFC had an effective virally-inactivated Factor VIII product available.

**12.141** The effectiveness of heat treatment to eliminate HTLV-III could not be tested until the virus was isolated and cell systems for the reproduction of HTLV-III antigen had been developed. That step was not announced until May 1984.<sup>220</sup> Earlier heat treatment had

been directed towards eliminating NANB Hepatitis and the elimination of HTLV-III was an incidental benefit.

### *Developments in late 1984*

**12.142** The SNBTS and Haemophilia Directors held a meeting on 29 November 1984.<sup>221</sup> The meeting had been arranged at short notice to discuss the implications of the finding of HTLV-III antibodies in Scottish haemophilia patients, and related topics including measures being taken by the SNBTS to prevent the transmission of AIDS by blood products. The cases of infection in Edinburgh and Glasgow were discussed. Dr Perry reported that it was anticipated that all PFC Factor VIII issued from about the beginning of January 1985 would be heat-treated.<sup>222</sup>

**12.143** The meeting in Scotland was, in part, preparation for the meeting of the UK Haemophilia Reference Centre Directors due to be held on 10 December 1984 (already discussed at paragraphs 12.101–12.105 above).<sup>223</sup> Professor Cash, Professor Ludlam and Professor Forbes attended the UK Reference Centre Directors Meeting, which was chaired by Professor Bloom. In his evidence to the Inquiry, Professor Ludlam said the meeting was stressful: the decisions reached were not easy and had to be made on the basis of limited data.<sup>224</sup> The commercial companies had kept much under wraps and there was very little published information on their work. There was apprehension that changes in treatment might make things worse for haemophilia patients. As a practical matter, Professor Ludlam would return to Edinburgh to find that (only) heat-treated product was to be available from the PFC from the end of December 1984 but he did not remember knowing that before the meeting. For him, as for Professor Cash in relation to initiating heat treatment, December 1984 was a 'terrible month'.<sup>225</sup> He was coming round to the view that the product was probably safe but he continued to have reservations. He had arranged for the testing of PFC heat-treated Factor VIII product in four patients earlier in December. If they had developed inhibitors,<sup>226</sup> he would not have wanted to use the product, notwithstanding the growing consensus among senior colleagues favouring heat-treated products.<sup>227</sup>

### **Central coordination**

**12.144** At a meeting of the SNBTS Directors on 11 December 1984,<sup>228</sup> Professor Cash expressed some of the frustration of Directors at the apparent lack of apparent central coordination:

Dr Cash said that he would make further representations to the SHHD that there should be a more effectively co-ordinated UK approach to transfusion and AIDS – this had already been recommended by the Scottish Directors. The Directors noted with regret that a second meeting of this Working Group on AIDS had not been arranged and that there appeared to be no evidence of co-ordination of the many splinter groups which existed.<sup>229</sup>

<sup>229</sup> Ibid [SGF.001.0137] at 0139–0140

**12.145** As noted above, however, on 14 December 1984 the UKHCDO produced an 'AIDS advisory document' to which Professor Cash had contributed. The treatment options presented in the document were set out in 'probable decreasing order of safety' in terms of the transmission of AIDS and demonstrated a preference for heat-treated NHS concentrates, followed by single-donor cryoprecipitate, heat-treated imported concentrates and, finally, unheated NHS concentrates and unheated imported concentrates. Use of DDAVP in mild Haemophilia A and von Willebrand's disease patients was recommended, if possible.<sup>230</sup>

**12.146** Effective heat treatment of PFC's Factor VIII product from December 1984 put an end to the risk for Haemophilia A patients treated in Scotland. There remained a risk for Haemophilia B patients until effective viral inactivation was introduced in October 1985. Two Glasgow patients acquired HIV infection from PFC Factor IX. One patient, the date of whose last negative sample is unknown, was first positive on 15 November 1985. The second was negative on 15 October 1985 but positive on 15 July 1986.

### **Should clinicians in Scotland have adapted their treatment regimes sooner than they did in response to the threat of AIDS?**

#### *The significance of early research into immune abnormalities*

**12.147** Until Professor Ludlam's findings in the spring of 1983 and the results of the Glasgow research later in that year, there was nothing in the direct experience of Scottish clinicians (as distinct from what might have been inferred from reports of experience elsewhere) to cause a radical re-assessment of haemophilia therapy. Those research projects showed that patients receiving concentrate therapy had developed immune abnormalities that shared many of the characteristics of those identified in other patient groups at high risk of progression to AIDS and diseases of the AIDS complex. It is appropriate to consider whether the discovery by laboratory testing of alterations in patients' immune systems, attributable to the administration of concentrates, marked the beginning of a period in which the continued use of factor products should have been reconsidered.

**12.148** Each of the two aetiologies postulated – the infective agent theory and the antigen overload theory – incriminated the use of concentrates in adversely affecting the immune systems of patients. As Dr Desforges commented in the *NEJM* of 13 January 1983, whatever the cause of AIDS, whether it was transmitted by an infective agent or was secondary to multiple antigenic exposures or some other unknown mechanism, haemophilia patients treated with concentrates were being exposed to a risk of immune system abnormalities which might progress to fatal illness. The nature of that risk and the extent to which it might affect haemophilia patients remained controversial and, as observed by Professor Ludlam, the spectrum of AIDS-related conditions differed to some extent between the groups. Kaposi's sarcoma appeared to be restricted to transmission by sexual routes and was not found in haemophilia patients.<sup>231</sup> However, haemophilia patients who developed AIDS did acquire *Pneumocystis carinii* pneumonia and that was associated with high mortality.

**12.149** The view of some haemophilia practitioners in the UK that British blood was likely to be essentially free of viruses and very safe and that British-produced Factor VIII was extremely unlikely to transmit the new disorder of AIDS, does not provide an answer to the risks associated with the antigen overload theory. If the antigen overload theory

<sup>230</sup> UKHCDO, 'Aids Advisory Document' [SGF.001.2388] at 2389–2390. Emphasis in original

<sup>231</sup> See Chapter 11, *HIV/AIDS Aetiology*, paragraphs 11.42–11.43

explained the development of immune disorders associated with AIDS related diseases in a significant number of haemophilia patients, with an established and increasing risk of morbidity and mortality, the continued use of concentrates in therapy would still have had to be justified on a balance of risk and benefit that took express account of the risks of progression to serious disease.

**12.150** Retrospective testing of blood samples showed that only a small proportion of the patients with immune irregularities were, in fact, HIV-positive at the time of the initial study. The outcome of this later research provided partial vindication of the conclusions reached by Professor Ludlam in 1983 supporting the antigen overload theory (or at least rejecting the transmissible agent theory as the sole cause of immune irregularities in all of the haemophilia patients studied). Nevertheless, the 1983 research provides a particular focus on the question as to when there was information that might have led to a change in use of factor concentrates in haemophilia therapy. It was widely appreciated that patients were developing AIDS-like immune abnormalities associated with concentrate therapy. The spectrum of AIDS-related conditions may have differed from those associated with AIDS caused by an infectious agent, but knowledge that there were significant immune deficiencies developing in patients that were attributable to concentrate therapy was in itself of potential importance.

**12.151** According to Professor Forbes, it was speculated by his group that something in the concentrates suppressed the immune system of recipient patients and that this made them more likely to be infected by the virus which was then appearing in concentrates.<sup>232</sup> On his account, it became accepted by most people in the course of 1983 that AIDS was transmitted by an infective agent.<sup>233</sup> He said that, as that became accepted, most people also came to think that AIDS would undoubtedly come to the UK in the course of time.<sup>234</sup> Already, haemophilia clinicians were looking at their patients to see if they had any of the features that might be an early warning of AIDS.

**12.152** It is important to emphasise that the 1983 research findings in Edinburgh and Glasgow included patients treated exclusively with PFC factor products produced from locally sourced plasma. The development of immune disorders in Haemophilia A patients in the main centres in Scotland was not associated with the use of Factor VIII imported from the USA to the extent that the prevalence of the disorders could be attributed solely to infective imported products: Scottish products were necessarily implicated. For those who accepted the transmissible agent theory as more likely, faith in the relative safety of UK blood could not have been supported, at least to the extent it had been until that point, in light of the 1983 research findings.

**12.153** Having regard to the Scottish research alone, the earliest point at which it might be suggested that an overall assessment of therapy should have begun was the spring of 1983. The issue became irrelevant at the end of December 1984: heat treatment effective to eradicate HTLV-III/HIV from blood products, and in particular Factor VIII, was developed at the end of December and was in routine use from early 1985. There were no recorded cases of infection transmitted by PFC heat-treated Factor VIII concentrates after that development.<sup>235</sup>

<sup>232</sup> Statement of Professor Forbes [PEN.015.0254] at 0257

<sup>233</sup> Professor Forbes – Day 17, pages 96–97

<sup>234</sup> Ibid page 103

<sup>235</sup> See paragraph 12.146 above: viral inactivation of Factor IX concentrate was not introduced until October 1985.

**12.154** The actual importance of the biochemical data as an indicator of a need to review clinical practice is limited, however, as there was no evidence of serious clinical disease among the patients studied in 1983. The initial study examined biochemical data collected over one month from patients treated during the previous five years.<sup>236</sup> It did not report progression in immunodeficiency and could not, without further study, have supported conclusions on future progression.

***Should Scottish clinicians have elected to use cryoprecipitate in preference to concentrates?***

**12.155** A particular question that arises is whether Scottish clinicians should have changed to the use of cryoprecipitate for Haemophilia A patients already receiving concentrate therapy, given the results of research in Edinburgh and Glasgow in 1983. In addition, other research evidence published early in 1983 reported that patients treated with cryoprecipitate did not develop impaired cell-mediated immunity (see paragraph 12.32 above). On the other hand, some clinicians thought that large quantities of cryoprecipitate were as likely as concentrates to transmit infection. Professor Ludlam noted that impaired cell-mediated immunity was not in itself a reliable indicator of HIV infection, as retrospective studies of patients exhibiting such abnormalities later confirmed. Furthermore, it was later to transpire that cryoprecipitate was, in fact, responsible for the transmission of HIV, albeit at greatly reduced rates and not in the UK, so far as is known to the Inquiry.<sup>237</sup> As against the practical problems associated with a switch from concentrate therapy to cryoprecipitate discussed below, however, contemporaneous evidence suggested that cryoprecipitate exposed recipients to less risk of immune deficiencies than concentrates. Some clinicians did advocate a switch on that basis, with limited success (resulting in few patients making the switch). It is important to note the recorded use of cryoprecipitate, as background to the discussion of the question.

**Use of cryoprecipitate in Scotland**

**12.156** There was extensive use of cryoprecipitate in many regions of Scotland. Recorded use over the period 1981–85, so far as the Inquiry's researches have shown, is as follows:

**Table 12.1: Use of Cryoprecipitate (units): Scottish Haemophilia Centres 1981–85**

	1981	1982	1983	1984	1985
RIE	720,160	612,000	341,700	139,000	127,680
GRI	56,650	40,950	136,550	121,100	223,990
Yorkhill	29,200	7050	30,500	32,340	27,930
Aberdeen	86,480	20,510	10,710	9030	10,300
Dundee	48,800	1370	4240	2560	0
Inverness	0	0	1540	0	0

<sup>236</sup> Carr et al, 'Abnormalities of Circulating Lymphocyte Subsets in Haemophiliacs in an AIDS-Free Population', *The Lancet*, 30 June 1984; 1431–1434 [LIT.001.0425]

<sup>237</sup> A 1990 study reached the conclusion that the transfusion of HIV-1 positive blood or blood products of any type (including cryoprecipitate) infected 90% of recipients: Donegan et al, 'Infection with human immunodeficiency virus type 1 (HIV-1) among recipients of antibody-positive blood donations', *Annals of Internal Medicine*, 1990; 113; 733-739. It appears that the relatively low rate of HIV transmission by cryoprecipitate was a result of the smaller number of donors (sometimes single donors and sometimes 'small pools' of 10–20 donors) contributing to the preparation of that product, particularly as compared to large-pool concentrates where many thousands of units of blood were used. Accordingly, cryoprecipitate was apparently responsible for the transmission of HIV in several countries which used only, or mainly, cryoprecipitate in the treatment of haemophilia patients (although not, so far as is known to the Inquiry, in the UK) albeit at a significantly reduced rate.

**12.157** Inverness used almost no cryoprecipitate over that period; PFC Factor VIII was used almost exclusively. Dundee used cryoprecipitate in 1981, as the centre had in previous years. In that year and later, however, it accounted for only a small percentage of total therapy which, as noted above, was based on almost exclusive use of PFC Factor VIII. Neither centre had a case of HIV transmission. In Aberdeen, use of cryoprecipitate fell over the period and the use of PFC Factor VIII grew proportionally.

**12.158** In Edinburgh, use of cryoprecipitate was reduced following Professor Ludlam's appointment. It remained high, in absolute and relative terms, however, throughout the period of maximum exposure of coagulation disorder patients to HIV. Cryoprecipitate was used in Edinburgh for vulnerable groups, including children. A change of practice would have affected older children and adults, many of whom would have been on home treatment programmes. Throughout that period, Professor Ludlam used considerably more cryoprecipitate than Professor Forbes, both absolutely and, taking into account that the GRI had a consistently higher number of registered patients than Edinburgh over this period, also as a ratio of their haemophilia patient populations.

**12.159** The position at the GRI is less easy to describe. Professor Forbes thought that the use of cryoprecipitate at the GRI might explain the low prevalence of HIV infection in his patients, but his evidence on this point is not supported by the analysis of the actual use of therapeutic materials in his centre. Professor Forbes' recollection of detail had clearly suffered with the passage of time. Cryoprecipitate was indeed used at the GRI but Professor Forbes' evidence on its use was less precise and it is not possible to define sub-groups with any degree of certainty. The recorded use, based on the materials available to the Inquiry, is preferred as evidence of practice at the GRI.

**12.160** The regime at Yorkhill changed after Professor Hann was appointed, reflecting both his previous interest in immunocompromised patients and his faith in the quality of the UK blood supply. Early reports of what became known as HIV infection were related to sexual behaviour and intravenous drug use but – partly through a 'corridor discussion' at the Stirling conference on immunocompromised patients in June 1982 – at an early stage Professor Hann considered it a 'possibility' that haemophilia patients would come to be affected.<sup>238</sup> By late 1983, Professor Hann said that he was 'becoming more convinced that this was a blood product transmissible disease' and that he had to do everything he could to minimise that risk.<sup>239</sup>

**12.161** He defined a 'difficult interim period' in therapy between May 1983, when the discovery of LAV (later proved to be identical to HTLV-III) was published, and late 1984, when the HTLV-III virus had been isolated and some of the patients were found upon testing to have antibody to the virus.<sup>240</sup> Although the development of tests was important, Professor Hann noted that there were still unresolved questions. The sensitivity and specificity of the tests was not clear and, more fundamentally, 'we didn't know what positivity meant'.<sup>241</sup> It was not clear whether positivity was transient or permanent and it was not known what proportion of those testing positive would progress to AIDS.<sup>242</sup>

---

<sup>238</sup> Day 21, page 46

<sup>239</sup> Day 31, page 105

<sup>240</sup> Day 21, Pages 68–9

<sup>241</sup> Day 31, page 21

<sup>242</sup> Ibid pages 21–2

**12.162** Professor Hann shared the concerns of many Haemophilia Directors about the use of cryoprecipitate, discussed below, particularly as this would have affected home therapy programmes. Nevertheless, he said that cryoprecipitate treatment may have been recommended as the first option for newly diagnosed patients in that period.<sup>243</sup> He believed that, in relation to a child who was already receiving Factor VIII concentrate in late 1983, he would have offered the possibility of ceasing concentrate therapy and returning to cryoprecipitate<sup>244</sup> and he was almost certain that in late 1983 he did change some patients over to cryoprecipitate and continued others for longer than he would have done previously.<sup>245</sup> Professor Hann's patients at Yorkhill were children, however: in due course Yorkhill patients were transferred to the GRI for treatment in their teens and as adults. He was not therefore confronted with the problem of changing the treatment regime of adults already settled on concentrate therapy and, in particular, the home therapy programme widely agreed to be advantageous.

**12.163** With the exception of Yorkhill, the picture that emerges overall, is that clinicians used cryoprecipitate on a selective basis, distinguishing children and other vulnerable groups from those settled on concentrate use and doing so on a broad precautionary basis rather than because they were committed to the infective agent theory of transmission.

#### The decision not to switch to cryoprecipitate use generally

**12.164** Dr Jones' editorial in the *BMJ* of 10 December 1983 provides a reference point in English practice.<sup>246</sup> Against the background of a view that there was no evidence that any product, 'commercial or volunteer', was free from the risk of transmitting AIDS, he commented that, for the moment, it would be sensible to treat very young severely affected children with cryoprecipitate, and that DDAVP or porcine material should be used in mildly affected haemophilia patients, von Willebrand's disease patients and carriers of those disorders. His advice was not significantly different from that observed in Scotland and favoured a discriminating approach to product selection.

**12.165** A similar approach was reflected in discussion at the Reference Centre Directors' meeting on 10 December 1984, at the end of the period. The AIDS Advisory Document of 14 December 1984 set out clearly the Reference Centre Directors' recommendations on therapy. The use of heat-treated imported concentrate was recommended after heat-treated UK concentrate and cryoprecipitate and fresh frozen plasma. Until imported heat-treated concentrates became readily available, that aspect of the advice would have had little practical effect, especially in England and Wales. Dr Winter and those of his colleagues who had no alternative to the use of commercial concentrates were in the vanguard of clinicians seeking to use heat-treated concentrates from May 1984. They were not able to obtain sufficient supplies for general use until later in the year. From a practical point of view, cryoprecipitate and fresh frozen plasma had become preferred alternative products for most clinicians and would remain so for some time, notwithstanding reservations about their use.

**12.166** The Haemophilia Reference Centre Directors' recommendations comprised a turning point in guidance. Until then there was no authoritative statement in the United Kingdom favouring cryoprecipitate for general use. There was a minority view held by

<sup>243</sup> Day 21, page 68

<sup>244</sup> Day 31, Page 25

<sup>245</sup> Ibid Page 27; Day 21, page 68

<sup>246</sup> Jones, 'Acquired immunodeficiency syndrome, hepatitis and haemophilia', *British Medical Journal*, 1983; 287: 1737-1738 [LIT.001.0243]

some clinicians, led by Dr Ratnoff in the USA and echoed by Dr Galbraith in the UK, that current therapy regimes should have been radically reviewed as soon as there was evidence of a possible association between factor concentrates and infection with a presumed agent of transmission of AIDS; that use of concentrates should have been abandoned or suspended; and that patients generally should have been prescribed cryoprecipitate.

**12.167** That view received limited support from Dr Desforges' editorial in the *New England Journal of Medicine* of 13 January 1983.<sup>247</sup> It was opposed by Dr Kernoff in his article 'AIDS and Haemophilia', in the Haemophilia Society's publication *The Bulletin*, edition 33, No 1, January 1983.<sup>248</sup> On 17 October 1983, Professor Bloom's advice in answer to Dr Chisholm of Southampton was that patients should not be encouraged to go over to cryoprecipitate for home therapy but should continue to receive the NHS or commercial concentrates in their usual way.<sup>249</sup> In December 1983, Dr Jones wrote that cryoprecipitate should be used to treat very young, severely affected children. Professor Bloom repeated his views at a meeting of the UKHCDO held in December 1983. There was a large body of informed opinion that rejected the Ratnoff/Galbraith approach.

**12.168** The question whether clinicians should use cryoprecipitate was discussed in these exchanges in terms of the selection of appropriate forms of therapy for specific groups of patients. One might suggest, in the light of later knowledge, that the decisions taken and the advice tendered were to the disadvantage of some NHS patients. It would, however, be impossible to criticise them as wrong decisions, either on the basis of the information taken into account or on the basis of the conclusions drawn from that information. Having regard to the published statements of leaders among the haemophilia clinicians, Professor Hann in Scotland and Dr Winter in England were very much in the minority in adopting the infective agent theory at an early stage in the AIDS epidemic and adapting their treatment programmes accordingly, so far as they were able to do so. Moreover, it is important to emphasise the extent to which cryoprecipitate was in fact used elsewhere: the advice on product selection was generally reflected in clinical practice.

### The impact on home therapy programmes

**12.169** The patients who would have been affected by a general switch to cryoprecipitate would be those already established on concentrate therapy, often on a home treatment basis, and those requiring frequent or heavy doses of concentrate. There was a widely held view in the UK that cryoprecipitate was not suitable for home treatment.<sup>250</sup> It was also limited in supply.<sup>251</sup>

**12.170** Under those circumstances, haemophilia patients would have required to attend hospital for all treatment. Beyond the inconvenience that would be caused by moving patients from home treatment with concentrates to hospital treatment with cryoprecipitate, there were clinical reasons for resisting such a move. Even under home treatment programmes using concentrates, cerebral bleeding was still, at the material time, the leading cause of death amongst haemophilia patients: in the UK, between 8 and 19 patients died annually from cerebral bleeds before they could attend hospital in this way. Professor Ludlam considered it inevitable that such deaths would have increased, were patients required to attend hospital for cryoprecipitate treatment. Moreover, as cerebral

<sup>247</sup> Desforges, 'AIDS and the preventive treatment in hemophilia', *New England Journal of Medicine*, 1983;308: 94–95[LIT.001.0040]

<sup>248</sup> *The Bulletin*, Edition 33 No. 1 [PEN.016.0595] at 0605–0606

<sup>249</sup> Minutes of the 14th meeting of UK Haemophilia Centre Directors Held on Monday 17 October 1983 [SNB.001.7517] at 7526

<sup>250</sup> Dr Winter – Day 16, page 25; Professor Hann – Day 31, page 27; Dr Pettigrew – Day 20, page 21

<sup>251</sup> Dr Winter – Day 16, page 26

bleeds were often 'spontaneous', by the time a patient arrived at hospital for treatment, 'very severe brain damage ... often occurred'. Finally, the increased morbidity associated with delayed treatment at hospital would not have been limited to cerebral bleeds: haemarthroses, left untreated until admission to hospital, would result in 'excruciating and protracted pain' and bed rest for around 10 days. As a consequence of the disuse of the joint and bed rest, 'there would be atrophy of the muscles ... and the weakened muscles would predispose to further haemorrhage'.<sup>252</sup> Professor Ludlam noted that patients under Dr Ratnoff's care had in fact resisted his proposal to switch to cryoprecipitate use, 'despite the apparently much higher risk in the USA of haemophiliacs developing AIDS in the early-mid 1980s'. In oral evidence he recalled that, of around 90 patients under his care, only five followed Dr Ratnoff's advice.<sup>253</sup> Professor Hann noted that, principally because of the inevitable impact changing from home therapy to hospital-based cryoprecipitate therapy would have on patients and their families – a point the Haemophilia Society 'repeatedly made' during the period – the majority of families declined the offer to switch to cryoprecipitate use at Yorkhill.<sup>254</sup>

**12.171** There was clearly conflicting evidence. Professor Hann found that some of his patients were willing to switch to cryoprecipitate, or remain on it for longer than would have been normal. His patients were children, however, and his background had been in infections in patients with immune deficiencies and leukaemia and cancers associated with immune deficiencies. He offered his patients a choice, as Professor Ratnoff had done in Cleveland. Professors Ludlam and Forbes, along with the rest of the Scottish clinicians, did not do so and continued using concentrates for the majority of their patients. Although they had both carried out studies into immunological abnormalities, neither study reported *progression* in immunodeficiency and neither clinician knew what the findings of their studies meant. Due to the unstructured, preliminary character of those studies, a full research programme following up on them would have been required if reliance was to be placed upon their conclusions in instructing any changes in the approach to therapy.

### Practical issues

**12.172** The narrative of the evidence indicates that there would also have been practical problems if there had been an attempt to revert to more or less exclusive use of cryoprecipitate. That was the view, for example, of the Sub-Committee on Biological Products of the Committee on the Safety of Medicines on 13 July 1983 (see paragraph 12.65 above). Professor Ludlam considered that it would have been necessary to invest considerable sums of money to purchase equipment such as centrifuges and fridges.<sup>255</sup> Dr Galbraith's proposal that concentrates manufactured in the USA from blood donated after 1978 should be withdrawn from use was held to be not feasible in the UK on the basis of supply.

<sup>252</sup> Professor Ludlam's Witness Statement [PEN.015.0445]; Dr Pettigrew noted three relevant case histories, one a case of a child with haemophilia, insufficiently treated at a local hospital when he experienced a bleed, who died of intracranial bleeding; and two cases of severely affected boys with haemophilia who sometimes required more than one visit daily to treat bleeds. Day 20, page 13

<sup>253</sup> Day 19, pages 29–31. See Ratnoff et al, 'Hemophilia and the Acquired Immunodeficiency Syndrome', *Annals of Internal Medicine*, 1985; 102(3)[PEN.016.1171]. In his statement, Professor Ludlam wrote: 'The suggestion that patients should be switched from concentrate to cryoprecipitate would have resulted in their attendance at hospital for all treatment (ie abandoning home therapy). Where this was recommended in Cleveland, USA, it was not accepted by the patients (despite the apparently much higher risk in the USA of haemophiliacs developing AIDS in the early-mid 1980s). The proposed increase in use of cryoprecipitate, instead of concentrate, in the USA did not find favour amongst patients, and it was also associated with very significant HIV infection.' Professor Ludlam's Statement [PEN.015.0445] at 0448

<sup>254</sup> Day 31, page 27

<sup>255</sup> Professor Ludlam's Statement [PEN.015.0445] at 0454

**12.173** Those were factors that clinicians and others were entitled to have regard to but it is questionable whether they would have been conclusive, or even material, if it had been understood that the relative risk of transmission of HIV infection by use of concentrates was so high that their continued use exposed patients to serious morbidity and mortality risks when an alternative – the use of cryoprecipitate – was available and could have been used notwithstanding the difficulties involved. In other words, in a question of patient safety, the decision of the Sub-Committee on Biological Products of the Committee on the Safety of Medicines was hardly credible unless the risk that was implicitly accepted was of such a low order as to be dismissed. Difficulties in process change would have been real, but those difficulties would have had to be addressed if the difference made was a real reduction in the perceived overall risk to patients.

*Should Scottish clinicians have made greater use of DDAVP?*

**12.174** Dr Winter noted that ‘a good number’ of mildly affected haemophilia patients and von Willebrand’s disease patients in the UK contracted HIV through contaminated blood products; he considered that switching mildly affected patients to DDAVP might have prevented this, ‘[o]ne wonders why they were ever treated with concentrate. Because they would have been suitable for DDAVP treatment’.<sup>256</sup>

**12.175** It is appropriate to consider this issue, not least because advice regarding the use of DDAVP appeared regularly in guidance on the selection of therapeutic materials in the USA, in the UK generally and in Scotland.<sup>257</sup>

**12.176** As noted at paragraph 12.31, Desmopressin, otherwise known as DDAVP, is a synthetic replacement for the naturally-occurring brain hormone called vasopressin. As it is not derived from human blood, it was not capable of transmitting HIV. Administered to patients with mild Haemophilia A and von Willebrand’s disease, it releases Factor VIII from the lining of blood vessels, allowing normal clotting to occur. It is important to note, however, that not all such patients are responsive to DDAVP and that, while it is an important and useful drug for those patients who are responsive, it is ineffective in patients with moderate or severe haemophilia and those mildly affected patients who do not respond to it.<sup>258</sup> Professor Ludlam said that, at the point of diagnosis, his practice was to give a ‘test dose’ of DDAVP to determine whether a mildly affected haemophilia or von Willebrand’s disease patient was responsive to the drug.<sup>259</sup> Professor Lowe said that the same practice applied at the GRI.<sup>260</sup>

**12.177** DDAVP is not generally considered useful in response to a spontaneous bleed of any real severity: more immediate treatment is usually required than DDAVP can provide. Professor Forbes stressed that DDAVP was principally used for elective procedures, such as minor operations or tooth extractions, and that it was rarely used to treat bleeds.<sup>261</sup> Professor Ludlam, who had a long-term clinical and research interest in DDAVP,<sup>262</sup> generally agreed but noted that DDAVP could be useful in treating some minor bleeds (giving a nose bleed as an example) or prophylactically in advance of minor operations (again, such

as tooth extraction) but not for bleeding into joints.<sup>263</sup> He noted that at his centre, 'it was standard practice to use DDAVP if that was suitable'.<sup>264</sup>

**12.178** In addition to the relatively limited number of patients for whom DDAVP was suitable, its use was also associated with side-effects and it had to be used with care. Professor Forbes noted that DDAVP is 'not without its own problems' and that 'it could not therefore be used routinely'.<sup>265</sup> In oral evidence, he stated that 'we did use it but with some caution'.<sup>266</sup> In particular, the therapeutic use of DDAVP is associated with fluid retention and changes in blood pressure. This did not constitute a general contra-indication for therapeutic use, as such problems as noted would only become apparent, if they arose, after administration. In his statement he noted that, at the GRI:

We were ... very aware of the possibility of using DDAVP in patients with mild disease who were having small traumas or small surgery. This we widely accepted, and was really very successful for a day or two's treatment only, for example one or two teeth or a very small procedure. During this time we also became aware of the other long term implications of DDAVP particularly fluid and electrolyte retention so it was used with some caution.<sup>267</sup>

**12.179** Professor Lowe agreed, stating that at the GRI '[t]he policy was to treat patients with mild Haemophilia A preferentially with DDAVP, where appropriate and tolerated'.<sup>268</sup> He added that DDAVP had only a short-term effect and that its effectiveness decreased with repeated administration:

It has a short-term effect. And usually after about 48 to 72 hours, if you are giving a daily or twice daily injection, you observe a phenomenon called tachyphylaxis, which is a reduced response, and this is because you are trying to stimulate release of the patient's own Factor VIII [or] von Willebrand factor complex .... [T]here is individual variation, but usually, after four doses of desmopressin, you don't get any more bang for your buck. So you have to bear in mind that limited situation.<sup>269</sup>

**12.180** Professor Hann stated that, from his appointment in January 1983, Yorkhill operated a policy whereby mildly and moderately affected Haemophilia A and von Willebrand's disease patients were treated preferentially with DDAVP (where a response to its use had been demonstrated). He noted that shortly after his arrival at Yorkhill, he made these policies 'explicit' and 'spent the first few months of my job writing them down' in a specific set of protocols. He stressed, however, that this approach 'was not always feasible or appropriate' – DDAVP is not considered safe for very young children (under one year of age) and was contra-indicated in those with fluid retention or neurological problems (in whom it can cause convulsions). Like Professor Lowe, he pointed to the problem of tachyphylaxis, making it inappropriate in many surgical settings, and to the fact that some patients do not respond at all to DDAVP.<sup>270</sup>

<sup>269</sup> Day 54, page 67

<sup>270</sup> Professor Hann's Witness Statement [PEN.015.0370] at 0373

**12.181** Professor Ludlam also agreed with the reservations regarding DDAVP use. Asked whether this meant that DDAVP was a drug which had to be used with great care, he replied:

With a degree of circumspection, yes. Great care in small children, and particularly if you want to give repeated doses, because of the water retention. And also in patients who have atherosclerosis ....

So, although it's a very useful drug, it is not without its contra-indications.<sup>271</sup>

**12.182** Professor Lowe was the lead author of a letter to *The Lancet* in 1977,<sup>272</sup> the first to note the problem of progressive water retention associated with the use of DDAVP and which recommended that water intoxication should always be considered a potential side-effect, particularly after repeated administration. In oral evidence, he said:

I think the point I'm making is that desmopressin is not the panacea. It had a very useful place – let's not underestimate it – during the 1980s, in sparing many patients with haemophilia and von Willebrand's disease around the world from getting virus infections. So it has its place, but it's not the panacea. And you have to assess every patient individually across the whole spectrum of haemostatic agents, not only in this period of time that we are talking about, concentrates versus cryoprecipitate or fresh-frozen plasma ....<sup>273</sup>

**12.183** The numerical data on the use of DDAVP suggests that its use varied among Haemophilia Centres in Scotland. At Edinburgh, it is recorded as having been used in small amounts (between 6 and eleven international units) between 1984 and 1987, but not at any other time.<sup>274</sup> At Yorkhill, it was used in 1989 only (20 international units).<sup>275</sup> Aberdeen and Dundee used no DDAVP at all in the material period.<sup>276</sup> Inverness used varying amounts (between 4 and 108 international units) beginning in 1987 but used none before that date.<sup>277</sup> Glasgow Royal Infirmary was the centre which made most use of DDAVP. Although none was used in 1980, 1983 or 1984, in every other year between 1979 and 1987, use ranged between 229 and 978 international units. From 1988–1991, use ranged from 1210 to 1548 international units.<sup>278</sup>

**12.184** Ultimately, however, the most important point for this Inquiry to make in relation to the use of DDAVP is that, so far as the data available to the Inquiry show, no mildly affected haemophilia patient in Scotland contracted HIV from concentrate therapy. The comment made by Dr Winter in paragraph 12.174 above does not therefore apply in Scotland.

### *Use in Scotland of imported commercial products*

**12.185** Until commercial products imported from the USA were heat-treated to inactivate HIV, American Factor VIII posed a relatively high risk of transmission of infection. The experience at Yorkhill, where Dr Willoughby favoured the use of commercial concentrates until he was succeeded by Professor Hann, is persuasive evidence of the risk associated

<sup>278</sup> See Table 5 in Chapter 21, *Haemophilia Therapy – Use of Blood Products*

with older generations of product. Patients registered at the hospital numbered between 70 (1980) and 108 (1985). Twenty-one HIV infections in an average population of 90, just over 23%, exceeds by a considerable margin the experience elsewhere in Scotland. Excluding Yorkhill, the average for the rest of Scotland was just over 8% (39/480).

**12.186** On Dr Winter's evidence, the safety of the American product changed in 1984 with the adoption of effective heat treatment. Heat-treated product manufactured by Alpha Therapeutics was obtained in May 1984 and used on a named patient basis in Kent, St Thomas' Hospital and the Royal Free Hospital, London and in Sheffield. Dr Jones moved to exclusive use of commercial heat-treated Factor VIII at Newcastle before 10 December 1984, the date of the meeting of the UK Haemophilia Reference Centre Directors at which treatment policy was widely discussed. That was, however, too late for many patients at both the Kent and Newcastle centres where seropositivity was high. On 14 December 1984, the UKHCDO 'AIDS Advisory Document' summarised recommendations on treatment options and preferences. At this point, as events were to prove, PFC was on the threshold of routine production of heat-treated Factor VIII concentrate that, as with the commercial product, was in time found to be effective in inactivating HIV.

**12.187** The record of the meeting of 10 December reflects the dismay and deep uncertainty of the professional community, desperate to find a solution to a problem that had not been anticipated but which went to the very roots of their management of patients. It might suggest that more positive action could have been taken in the last quarter of 1984 to obtain US heat-treated products for all patients, as Dr Jones had done by December of that year. It is not likely that supplies could have been obtained earlier. Dr Winter, who had a long history of use of commercial products, initially had difficulty in sourcing sufficient quantities for all of his patients. Dr Jones' determination to use the products suggests that he would not have delayed in his efforts to obtain them. It remains a matter of speculation when commercial heat-treated products would have been available in sufficient quantities to meet total demand in the UK as a whole, or in Scotland in particular. It could not, however, have been earlier than late 1984.

**12.188** It is reasonably clear that a switch to imported heat-treated products would have been of little advantage to Scottish patients. Early in December 1984, the PFC began distributing its first heat-treated product to haemophilia centres. The product was despatched by carrier to Belfast, Aberdeen, Dundee and Inverness around 10 December. At the same time, the PFC itself delivered heat-treated product to Glasgow and Edinburgh.<sup>279</sup> In each case, the quantity delivered was about one month's supply. Full scale production of heat treated product took over from the beginning of 1985.

**12.189** There is no evidence available to the Inquiry to suggest that the UK or Scottish demand for heat-treated factor VIII concentrate for haemophilia therapy could have been met at any time during 1984 wholly from American pharmaceutical companies. The Haemophilia Reference Centre Directors recommendation on 10 December was that heat-treated product should be given to all patients, '*if freely available*'.<sup>280</sup> The market position remained uncertain at that date, when the PFC was already issuing a domestic heat-treated product.

<sup>279</sup> Arrangements set out in Dr Perry's letters to Haemophilia Directors [SGH.002.6506]. On 11 December, Dr Mitchell acknowledged receipt of product [SNB.007.4669].

<sup>280</sup> Notes of meeting [SNF.001.3850] at page 3853 (emphasis added)

### *The ethics of medical practice*

**12.190** The ethics of medical practice in this field are discussed in Chapter 32, *An Investigation into Systems in Place for Informing Patients about the Risks – Ethical Context*. In short, prior to 1988 there were no rules, relevant to such a situation as described in this chapter, requiring clinicians to consult their patients about potential changes in therapy. Furthermore, the approach of both Professor Forbes and Professor Ludlam throughout the 1980s was consistent with the advice that was to be provided by UKHCDO in mid-December 1984.

### **DISCUSSION**

**12.191** Sixty patients with bleeding disorders acquired HIV infection from treatment in Scotland (see Chapter 3, *Statistics*, paragraph 3.296). The infection of all but one of these patients can be associated with specific centres: Edinburgh, 23; GRI, 12; Glasgow Yorkhill, 21; and Aberdeen, 3. The remaining patient is known to have been infected in Scotland, probably at a hospital that was not a haemophilia centre. At least 18 NHS patients are known to have acquired HIV/AIDS transmitted by blood or blood component transfusion (see Chapter 3, *Statistics*, paragraph 3.321).

**12.192** All of the patients with bleeding disorders acquired their infection from blood factor concentrates. There is no recorded case in the UK of transmission of HIV related to the use of cryoprecipitate. The UKHCDO did not record relevant data of cryoprecipitate use, however, and it is not possible to be totally confident that transmission by infusion of infected cryoprecipitate did not happen. Transmission of HIV by cryoprecipitate certainly did occur in other countries. However it seems appropriate to proceed on the basis that, if there were any cases, they would be very few, and that cryoprecipitate generally was not responsible for transmitting HIV in the UK generally or Scotland in particular.

**12.193** Leaving aside the multiple infections of the Edinburgh Cohort,<sup>281</sup> there is no evidence of transmission of HIV to groups of patients in Scotland by use of SNBTS large-pool concentrates. On the evidence available to the Inquiry about the chemistry of plasma processing, the pool of plasma prepared for processing would be more or less uniformly affected by a component donation that was infected by a virus. On that basis, the pooling of plasma from the donations of many hundreds of individuals clearly created a risk that an infected donation might infect large numbers of recipients. The experience of the Edinburgh Cohort demonstrates that the risk was real. Most members of the Cohort have been shown by genetic analysis to have acquired the virus from a single source. The Inquiry has not recovered similar evidence for other infected individuals. Cryoprecipitate was pooled in general application at the point of administration: the dose for an adult patient might require 10–20 bags. An infected donation would still reach one recipient only, however. Had cryoprecipitate been used exclusively in the treatment of coagulation disorder patients throughout the AIDS period – roughly 1981–85 – then the risk of transmitting HIV infection would have been arithmetically reduced: the number of patients potentially infected could not have exceeded the number of infected donations.<sup>282</sup>

<sup>281</sup> A group of 18 RIE haemophilia patients infected with HIV by NHS products, discussed in Chapter 10 *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*.

<sup>282</sup> There is a theoretical risk that the use of mini-transfusions in neo-natal cases might have increased the risk, as happened in Italy but there was no evidence of similar practice in Scotland.

**12.194** In relation to risk, it is important to bear in mind that, untreated, haemophilia carries a high rate of serious and potentially fatal illness. The life expectancy data noted in this chapter provide one measure of the risk of fatal illness: bleeding was the most frequent cause of death before concentrate therapy was introduced. It is against that risk that the risks associated with therapy had to be balanced. The studies carried out by Professors Forbes and Ludlam suggested that profound immunosuppression occurred in patients treated with PFC Factor VIII. Those studies were of a preliminary nature and did not provide evidence of progression in immunodeficiency. More significantly, however, it became widely known in the autumn of 1983 that a haemophilia patient treated with concentrates had died of AIDS. Once it was apparent that immunosuppression could progress to fatal illness the risk/balance assessment changed: the risk of death from bleeding then had to be measured against the risk of death from HIV/AIDS. Decisions on therapy had to take account of a different context.

**12.195** The only alternatives at this stage were to cease entirely the use of blood products in haemophilia therapy or to endeavour to switch all Haemophilia A patients to cryoprecipitate. In relation to the period from autumn 1983 to December 1984, the point when heat-treated product began to be issued in Scotland, it is not possible to conclude that a general cessation of use of blood products should have occurred. Given the uncertain state of knowledge of AIDS and the risks posed by untreated haemophilia, it was reasonable for general treatment policy to continue to include the use of blood products, provided these were used on a more discriminating basis. The advice formulated at the Reference Centre Directors meeting of 13 May 1983 appears sound – that it was circumspect to continue to reserve NHS concentrates for children and mildly affected (adult) patients, rather than using concentrates imported from the USA. More specifically, the advice contained in Dr Jones's editorial in the *BMJ* in December 1983 that cryoprecipitate should be used for children and other options, such as DDAVP, considered for older patients, was prudent; one might have expected similar points to have been made by Professor Bloom at the UKHCDO meeting on 17 October 1983, rather than his seemingly unqualified endorsement of concentrate therapy.

**12.196** In relation to the suggestion that all Haemophilia A patients should have been switched to cryoprecipitate from around autumn 1983 onwards, several points need to be borne in mind. As with the proposition dealt with in the preceding paragraph, the general uncertainty surrounding the proportion of patients who would develop the profound immunosuppression being observed, and the proportion of that group who might not survive, was relevant. To be balanced against these unquantifiable risks were the known dangers of untreated haemophilia, as noted above. As Professor Lever put it, 'the risk-benefit ratio of being infected versus not receiving concentrates was not clear cut'.<sup>283</sup> Treatment was necessary and therapy with concentrates was well established. Clinicians and patients favoured concentrates rather than cryoprecipitate for understandable reasons, a preference also strongly supported by the well respected Haemophilia Society. In addition, it cannot be concluded that a mass switch to cryoprecipitate would have been practically possible.

---

<sup>283</sup> Professor Lever's Report [PEN.015.0517 at 0522

**12.197** Cryoprecipitate appears to have been utilised for particular groups of patients; on all of the evidence available to the Inquiry, that appears an appropriate general course. Issues concerning information given to individual patients, and the choices they were offered in relation to their own treatment, are dealt with in Part 5 of this Report.

## Conclusions

**12.198** Professor Lever's evidence is accepted: reassessment of the risk/benefit balance in the use of factor concentrates in haemophilia therapy became necessary when evidence of two factors was present: (i) the association of profound immunosuppression in patients with infusion of factor concentrates and (ii) death from immunosuppression.

**12.199** Independent of the cause of the immunosuppression in coagulation defect patients treated with factor concentrates, knowledge that there was an association between established therapy and immunosuppression in patients was a potential trigger for a reassessment of clinical practice. The studies reported in Edinburgh in May 1983 and in Glasgow in October 1983 were preliminary in nature: they demonstrated immunosuppression in patients treated with factor concentrates but did not, and could not, report *progression* in immunodeficiency. At that point, there had been no report of a UK haemophilia patient having died of AIDS. Nevertheless, published guidance and letters in journals at the time, as well as the records of materials used, suggest there was a general awareness of the importance of a discriminating approach to product selection in light of incomplete information.

**12.200** The association of immunosuppression in patients with haemophilia treated with factor concentrates and a potentially fatal outcome was established in the UK by the autumn of 1983. The general approach to the use of blood products in haemophilia therapy was reassessed and appropriately modified, insofar as references were made to the need to protect children and mildly affected patients in particular.

**12.201** The transmission of infection by infusion of PFC Factor VIII was established around the end of October 1984 in Edinburgh and the east of Scotland and in or about October 1984 in Glasgow and the west of Scotland. A further general reassessment of coagulation defect therapy was therefore necessary and took the form of the meeting and guidance issued in December 1984. The response in autumn 1984 of the Haemophilia Reference Centre Directors to emerging knowledge was appropriate and is not open to criticism.

**12.202** The use of imported heat-treated products was not an issue in Scotland so long as there was no evidence that the PFC product transmitted HTLV-III infection and so long as there was no evidence that the immunosuppression found in coagulation defect patients might progress to fatal illness.

**12.203** Having regard to the timing of the discovery that PFC materials transmitted infection, and the imminence of production of a safe product by PFC, the failure of Scottish practitioners to import and use US heat-treated products is not material.

## CHAPTER 13

### KNOWLEDGE OF VIRAL HEPATITIS NOW

#### Introduction

**13.1** This chapter provides an account of what is known now, in 2014, about Hepatitis C virus (HCV) infection, in particular in relation to the two affected groups with whom the Inquiry is concerned: blood disorder patients receiving therapy and people infected by blood transfusion in the course of medical or surgical procedures. Very little of what is described in this chapter about HCV was known, or could have been known, until well into the 1990s and much, indeed, has been understood only in the past few years.

**13.2** The information set out in this chapter is intended, particularly, to inform and illuminate the accounts provided by patients and their relatives of experiences of HCV infection narrated in Chapters 4 and 6 of the Report.

**13.3** As further background to an understanding of those accounts, this chapter also discusses the investigative procedures and forms of drug therapy associated with the diagnosis and treatment of HCV infection, with particular reference to the side-effects of treatment.

#### Background

**13.4** At the date of the Inquiry's Preliminary Report (2010), the group of hepatitis viruses had not been finally defined but it was thought there were six, viruses A to E and G, as described in a standard textbook of 2007.<sup>1</sup> The current view is that virus G is not a hepatitis virus in humans. Now known as GBV-C and a member of a family of flaviviruses, it causes hepatitis in marmosets but humans who are infected do not develop liver disease.<sup>2</sup> However, it cannot be assumed that the class is now closed: research continues. Equally, the signs, symptoms, natural history and complications of viral hepatitis, generally and for each specific disease, have been and are the subject of ongoing research and have not been finally resolved. Inevitably, expert perception and understanding of the manifestations of the diseases have changed over time. The natural history of each disease has some features that are generally recognised and are increasingly understood, however. In this changing environment, the Inquiry is particularly grateful to Professor Howard Thomas, Emeritus Professor of Hepatology, Imperial College, London, and Professor Peter Hayes, Professor of Hepatology and Honorary Consultant Gastroenterologist at the Royal Infirmary of Edinburgh (RIE), for their contribution to the understanding of the present state of knowledge of viral hepatitis.

**13.5** All five of the human hepatitis viruses currently recognised, A to E, are from different families of the virus kingdom. The viruses are grouped together because they all replicate in the liver and cause inflammation and fibrosis (scarring) in that organ.<sup>3</sup> Two of them, Hepatitis A virus (HAV) and Hepatitis E virus (HEV), are enterically transmitted, through the digestive system, and generally cause a self-limiting infection.<sup>4</sup> Rarely, HAV and HEV may cause fulminant (rapidly progressing) liver failure and a small proportion of patients die

<sup>1</sup> Hepatitis G was described at paragraph 2.10 of the Preliminary Report. The standard text was *Schiff's Diseases of the Liver*, 10th edition, 2007

<sup>2</sup> Professor Thomas – Day 52, pages 9–11

<sup>3</sup> Preliminary Report, paragraphs 2.5 and 2.6

<sup>4</sup> Preliminary Report, paragraphs 2.8 and 2.9

from this complication. In general, however, after two or three months the patient's liver function tests and the architecture of their liver return to normal. The virus is eradicated and the person will have protective immunity for the rest of their life against the virus causing the infection.

**13.6** Hepatitis B and C viruses (HBV and HCV, respectively) are parenteral, blood-borne infections,<sup>5</sup> transmitted by the introduction of infected material through the skin or mucosal surfaces.<sup>6</sup> They may cause acute, clinically significant hepatitis. A proportion of those infected go on to develop chronic infection. The definition of the 'chronic' condition is statistically based and internationally agreed.<sup>7</sup> In Hepatitis B and C an infection is considered to be chronic if it continues for longer than six months after identification of the virus or antibodies to it.<sup>8</sup> 'Acute' hepatitis is defined as a self-limiting illness lasting less than six months. Estimates of clearance rates for Hepatitis C within the first six months vary from 20% to around 30–40%.<sup>9</sup> The remaining 60–80% of patients progress to chronic infection.

**13.7** In Hepatitis B and C cases, many acute infections remain unidentified: they may be asymptomatic. If there are symptoms, they tend to occur in the first few months after infection, whether acute or chronic, and tend to be more severe in a patient with acute infection. These symptoms can include flu-like symptoms, jaundice, loss of appetite and abdominal pain. In the case of an acute self-limiting infection, the level of liver enzymes in the patient's blood, most commonly alanine aminotransferase (ALT), peaks typically at about three months and falls to a persistent normal level at about six months. If HCV is cleared in the earlier stages of developing fibrosis, either spontaneously or as a result of treatment, then the liver will ultimately remodel and go back to normal and the patient will have been cured both of the presence of the virus and of the liver disease.

**13.8** In chronic infection, after the initial three-month peak, ALT levels continue to fluctuate, often above the upper limit of normal. Chronic infection puts the individual at risk of 'progressive liver disease', the risk that fibrosis will develop to cirrhosis and this, in the case of cirrhotic patients, in turn creates the greatest risk of developing complications.<sup>10</sup> Progression to cirrhosis indicates that not only is there significant fibrosis but also that the normal architecture of the liver has changed to include structurally abnormal nodules.<sup>11</sup> At that stage the process is probably irreversible: while a patient may manage to clear HCV permanently, the cirrhosis will remain with its potential complications.<sup>12</sup>

**13.9** The complications of cirrhosis may be very serious and life-threatening. Two of the main complications of cirrhosis are hepatocellular carcinoma (HCC, primary cancer of the liver cells) and bleeding from oesophageal varices (varicose veins in the stomach and gullet).<sup>13</sup>

<sup>5</sup> Strictly speaking a parenteral infection is one spread by a means other than by the introduction of a pathogen to the gastrointestinal tract and, in this general way, does not refer only to blood-borne infections. Medical literature of the time, however, used the term parenteral, at least as regards hepatitis, to mean 'blood-borne' and this usage is retained here.

<sup>6</sup> Hepatitis D, referred to in the Preliminary Report at paragraph 2.11, is also a parenterally transmitted RNA virus which affects those already infected with Hepatitis B. It is not relevant to the NHS patients discussed in this Report.

<sup>7</sup> Professor Thomas – Day 52, pages 72–75; Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1076

<sup>8</sup> Professor Thomas – Day 52, page 12 and pages 72–73

<sup>9</sup> Thein et al, 'Prognosis of hepatitis C virus-infected Canadian post-transfusion compensation claimant cohort', *Journal of Viral Hepatitis*, 2009; 16:802-813 [LIT.001.4184] at 4187; Professor Thomas – Day 52, page 13 and pages 56–57; Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1074

<sup>10</sup> Professor Thomas – Day 52, pages 58–59. Increasing fibrosis is measured on the Ishak scale. The scale runs from 1 (no fibrosis) to 6 (cirrhosis) at which stage the individual is at risk of hepatocellular carcinoma.

<sup>11</sup> Professor Hayes – Day 78, pages 83–4

<sup>12</sup> Professor Thomas – Day 53, page 58

<sup>13</sup> Professor Thomas – Day 52, pages 8–12, generally

Further complications of cirrhosis, encephalopathy (damage to the brain characterised by confusion, cognitive impairment and lethargy) and ascites (the accumulation of fluid in the abdomen), are signs of liver failure.<sup>14</sup> A person with cirrhosis of any cause has a risk of developing a hepatocellular cancer of 2–3% a year.

**13.10** In general, the progression to End Stage Liver Disease (ESLD) encompasses all of the stages mentioned. The march of events is: acute infection, failing to resolve, leading to chronic infection and then cirrhosis, and then on to the risks of liver cancer and/or liver failure.<sup>15</sup> With very few exceptions, only those HCV-infected individuals who have developed cirrhosis are at risk of liver cancer. In a very small proportion of cases, HCC may develop at an earlier stage.<sup>16</sup> In chronic HBV, too, HCC develops after cirrhosis is established. However, in those infected with HBV in infancy, a pattern of infection found more commonly in the Far East and Africa, HCC may also develop in the non-cirrhotic liver.<sup>17</sup>

**13.11** The prevalence of these diseases varies across the world and that is frequently due to causes that are at best indirectly relevant for present purposes. Worldwide, some 350 million people have chronic Hepatitis B, three-quarters of whom were infected at birth. Most of these individuals live in China.

**13.12** Worldwide, 170 million people are estimated to have Hepatitis C.<sup>18</sup> Causes of high prevalence of HCV vary. In Bolivia it may be due to tribal scarification practices and in Egypt, which has the highest prevalence of HCV infection in the world, it is probably related to a programme of injection to treat the endemic parasitic disease schistosomiasis from the late 1950s to the early 1980s, which involved the use of unsterilised equipment. There is twice the prevalence of Hepatitis C infection in the general population of the USA when compared with the UK.

**13.13** In the UK as a whole, chronic Hepatitis B (now generally a smaller problem than Hepatitis C) has its highest prevalence in first-generation migrants from the Far East, Africa or the Mediterranean where prevalence of the disease is high. The low prevalence of the disease in the general public in the UK was attributed by Professor Thomas to the introduction of universal standards within, and provision of sterile equipment throughout, the National Health Service.<sup>19</sup> In Scotland, while the true prevalence of Hepatitis C in the population as a whole remains unknown,<sup>20</sup> the number of known cases continues to increase with improved and wider ascertainment. A great many of both new infections and newly discovered infections occur amongst intravenous drug users (IVDUs), past or present.

## Biology of HCV

**13.14** In Hepatitis B the genetic information for the virus is contained in deoxyribonucleic acid (DNA). In Hepatitis C the genetic information for the virus is contained in ribonucleic acid (RNA): it is an RNA virus. HCV exhibits considerable sequence variation, or genetic

<sup>19</sup> Ibid page 48

<sup>20</sup> See, however, Chapter 3, *Statistics*.

heterogeneity.<sup>21</sup> There are six major genotypes, with additional differences between the strains (or 'quasi-species')<sup>22</sup> found within a single genotype. The biological behaviour of the different genotypes is encoded by the genetic structure of the virus<sup>23</sup> and there are major biological differences between the genotypes which have a bearing on treatment. Treatment of Genotype 1 virus infection with Interferon and Ribavirin (the first two forms of drug therapy for Hepatitis C which became available) cures a lower proportion of cases than the same treatment of Genotypes 2 and 3.<sup>24</sup> An individual, and particularly an individual with haemophilia, may have been infected with more than one genotype of HCV and may be co-infected with Hepatitis B. In such cases the replication of one virus may interfere with the replication of the other or others, which become apparent only when the first is cleared.<sup>25</sup>

**13.15** As with each of the hepatitis viruses, the different genotypes of HCV are not distributed uniformly. The description of the distribution noted in the Preliminary Report remains valid.<sup>26</sup> In the UK as a whole about 50% of HCV is Genotype 1, with Genotypes 2 and 3 making up the other half. In the USA, Genotype 1 predominates, in particular in the haemophilia population, with Genotype 3 coming into play later.<sup>27</sup>

**13.16** HCV RNA is detectable in acute, self-limiting, cases up to about six months but not thereafter, since the body will have dealt with the virus. In chronic HCV infection the virus RNA may continue to be detectable indefinitely and is the signature of the chronic condition.<sup>28</sup> The level of viraemia (virus in the blood) probably affects the severity of liver disease.<sup>29</sup>

**13.17** The likelihood of developing a self-limiting acute infection is related to an individual's genetic make-up and, in particular, the immune system's recognition proteins (haplotype (HLA type) proteins). A person's HLA type is genetically determined and does not change. Certain HLA types confer a stronger possibility of leading to clearance of the virus after infection. The individual's HLA type forms a significant component in the risk matrix, generally and in relation to the risk of re-infection following clearance. If an individual is infected and clears the virus spontaneously, the same outcome is likely to follow a subsequent infection.<sup>30</sup>

**13.18** The sequelae of infection with HCV (the complications associated with the disease) appear to vary among populations in different geographical areas. For example, infection can be associated with a risk of non-Hodgkins B cell lymphoma in southern Europe but is rarely so associated in the UK. Care is therefore needed in applying information from different geographical areas of the world to the UK generally and, within the UK, to Scotland in particular. Understanding of some consequences of infection is still developing.

<sup>21</sup> Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1072–3; Professor Thomas – Day 52, pages 38–39

<sup>22</sup> Professor Hayes – Day 78, page 98

<sup>23</sup> Professor Thomas – Day 52, page 40

<sup>24</sup> 'Cure' in this context is the permanent eradication of the virus from the patient which, in pre-cirrhotic individuals, allows the liver to return to normal. See paragraphs 13.97–13.101 below for further information on current treatment for each of the main genotypes, which takes account of these factors.

<sup>25</sup> Professor Thomas – Day 52, pages 60–61. In practice, Professor Hayes stated that it is very rare to find in clinical practice an individual with more than one genotype, as distinct from quasi-species of a single genotype: Professor Hayes – Day 78, page 98.

<sup>26</sup> Preliminary Report, paragraph 2.21

<sup>27</sup> Professor Thomas – Day 52, page 49

<sup>28</sup> Professor Thomas – Day 52, page 73; Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1075–76. After 20–30 years viral DNA may no longer be readily detected in up to 10% of chronically infected patients. See Watanabe et al, 'Spontaneous elimination of serum hepatitis C virus (HCV) RNA in chronic HCV carriers: A population-based cohort study', *Journal of Medical Virology*, 2003; 71: 56–61 [LIT.001.4198]

<sup>29</sup> Professor Thomas – Day 52, page 58

<sup>30</sup> Ibid pages 57–58; Day 53, pages 61–62

For example, impaired cognitive function ('brain fog') and depressive mood disorders, which occur in some cases, are now thought to be causatively related to HCV infection.<sup>31</sup> Evidence for these sequelae strengthened with the discovery that, independently of the severity of liver disease, virus recovered from the brain of infected patients had a structure in common with that found in peripheral blood lymphocytes but different from the structure of the virus in the liver. The causal connection is now probably established.<sup>32</sup>

### Hepatitis C: Identification of the virus

**13.19** The discovery of HCV was announced by Chiron, a US pharmaceutical company, in May 1988.<sup>33</sup> Scientific details were published in April 1989.<sup>34</sup> In the same month details were also published of an enzyme-linked immunosorbent assay (ELISA) to detect antibodies to HCV.<sup>35</sup> The background to the discovery is discussed in more detail in Chapter 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards*. Chiron's work was a significant, and inventive, development in the knowledge of HCV infection. It laid the foundation for research into the genetic structure of the virus set out above and in much of the remainder of this chapter. In the context of transfusion-related transmission and blood product therapy-related transmission, post-transfusion HCV infection now appears to explain most if not all cases of what was once termed 'non-A, non-B Hepatitis' (NANB Hepatitis) virus infection.<sup>36</sup>

**13.20** Since the announcement of Chiron's discovery, research into the genomic composition of the Hepatitis C virus has identified variations which now support an increasingly sophisticated system of sub-classification. At the Inquiry's oral hearings, Professor Thomas noted that Japanese researchers had succeeded in growing the virus culture in one particular cell line within the previous five years.<sup>37</sup> There remain problems of easy and reliable replication. These problems affect the application of developing knowledge in the testing of new treatments and the preparation of a vaccine, for example. Research continues and it appears likely that much remains to be discovered before a complete description of the virus in its many sub-types, its sequelae and the most effective means of protection against and treatment for it can be attempted.

### The reproductive process of HCV

**13.21** During an episode of acute hepatitis in which the virus is eliminated, the body mounts an effective immune response, engaging the CD4 T-helper and CD8 cytotoxic cells. In general, the stronger the response the more likely the patient is to recover. Individuals who become jaundiced have a lower frequency of viral persistence than those who do not: the jaundice is a reflection of the immune system killing infected liver cells.<sup>38</sup> The

<sup>36</sup> As noted in Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraph 14.67, the expression 'non A, non B Hepatitis' (frequently abbreviated to 'NANBH' or 'NANB Hepatitis') was coined in the mid-1970s as a collective term for hepatitis from which, at that time, Hepatitis A and Hepatitis B, as well as cytomegalovirus (CMV) and Epstein-Barr virus (both of which can cause liver inflammation), had been excluded.

<sup>37</sup> Professor Thomas – Day 52, page 38

<sup>38</sup> Ibid pages 68–69

'price' of clearing the HCV completely and spontaneously from the body is often a more severe acute clinical illness. In patients developing persistent infection, the CD4 and CD8 responses are less strong, though still detectable, and clinical manifestations at the acute stage are often trivial or absent.<sup>39</sup>

**13.22** Where the virus persists, it must replicate. In order to replicate, a virus needs to use many of the enzymes within a living cell. It must, therefore, enter a cell which has a suitable point of entry on its surface. Liver cells have a surface receptor which normally transports fat into the cell, among other functions, and the envelope in which the Hepatitis C virus is contained has the appropriate physical configuration to bind onto the liver cell receptor. HCV gains entry to the liver by docking with the liver cell: the virus 'piggy-backs' its entry onto the normal receptor process.<sup>40</sup>

**13.23** When the virus enters the liver cell, it 'hijacks' the replication mechanism of the host cell: the RNA of the virus enters the protein-synthesising machinery of the cell, immediately making use of the apparatus of the cell to make more copies of itself. New viral particles of positive strand RNA are manufactured and then self-assemble in the cell: they 'encode' for a polyprotein comprising all of the structural and non-structural proteins of the virus. The new viral particles follow the same pathway through the cell as fat. The fat globules passing through the liver therefore incorporate virus particles.<sup>41</sup> The virus particles are then excreted from the cell, by the same structures that are normally used to get rid of fat from the liver cell and exit from the liver to circulate in the blood stream.<sup>42</sup>

**13.24** HCV does not damage or kill liver cells directly. Rather, the liver cells suffer because of the body's immune response to the virus: small protein molecules called cytokines are released to both shut down virus replication and kill the infected cells.<sup>43</sup>

**13.25** There are two highly variable proteins on the surface of the HCV envelope and the new virus particles produced are, in turn, highly variable, although the variability does not extend to shifting the virus from one genotype to another. Rather, HCV creates a swarm of quasi-species: every virus particle in the patient is slightly different in its RNA sequence.<sup>44</sup> Even within an individual infected with a single genotype the genetic sequence of each virus particle is different and changes over time as the virus comes under various selection pressures. Many of the different variations, the quasi-species, produced in replication will be non-viable (unable to replicate). Otherwise they are targeted, initially by the host's immune response and, in more recent times, by potentially therapeutic drugs such as the protease and polymerase inhibitors.

**13.26** The patient's antibody response may neutralise most of the virus particles that are viable. As virus neutralising antibodies are made by the host's immune response, new variants of the virus, which existing antibodies do not immediately neutralise are selected.<sup>45</sup> There will be a small number of quasi-species that have antigens (epitopes) that are not targeted by the patient's immune system and, because they are not neutralised, these become dominant and provide the virus with an advantage until the system adapts to find

<sup>44</sup> Ibid page 41

<sup>45</sup> Technically 'selected for'.

antibodies to them.<sup>46</sup> After a significant new antigen appears, it takes about 10 days for the immune system to produce an antibody.<sup>47</sup>

**13.27** HCV exhibits greater genetic diversity than most other viruses and this is a major contributor to the high rate of chronicity, the difficulty in producing a vaccine and the rapid emergence of virus strains that are resistant to new treatments such as protease, polymerase and NS5a inhibitors.<sup>48</sup>

**13.28** There are continuing issues relating to HCV infection. Professor Hayes commented on the changing understanding of the natural history of Hepatitis C over time.<sup>49</sup> In the early 1990s people did not know how aggressive the condition was and there is still considerable debate on this point. When a test for HCV infection became available, instead of confirming the diagnosis of NANB Hepatitis in the small number of people who had been so labelled, clinicians here and abroad found that large numbers of people who had not been suspected of having NANB Hepatitis were infected with HCV. In the UK the prevalence of HCV is low, at less than 1%. How the disease would impact on people's lives nevertheless became a major issue. The risk of progression to cirrhosis was originally estimated at 20% but the natural history of the disease is still unclear and is complicated by other major factors such as alcohol consumption and obesity. It is now thought that a large number of HCV-infected patients will go on to develop major complications, including cirrhosis and its sequelae.<sup>50</sup>

**13.29** As understanding of the characteristics of HCV has developed, it has become increasingly clear that advances in knowledge are dependent on the science of genetics and on the application of technology that was quite unknown at periods when exposure to risk, at least via transmission by blood or blood products, was greatest and the response to infection was least effective.

**13.30** Overall, the circumstances in Scotland were very similar to those described above for the UK as a whole, subject to some variation in percentages.<sup>51</sup>

### **Risk of transmission of HCV by blood, blood components and blood products**

**13.31** It is important to note that the risk of transmission of Hepatitis C by transfusion of blood or blood components, or the infusion of blood products, has greatly diminished following the introduction, in current practice, of highly developed testing procedures which are rigorously applied. Separate samples are taken at the time of blood donation to be tested for blood group (ABO, Rhesus and sometimes more minor groups) and microbiology markers (syphilis, HIV, HCV, HBV, and HTLV-I and II by serology and HIV, HBV and HCV by nucleic acid testing). All platelet donations are tested for bacterial contamination.<sup>52</sup> Apart from HCV, serology tests also look for patients with antibodies to infections. Nucleic acid testing is based on polymerase chain reaction, which amplifies RNA or DNA and is highly sensitive. Currently, donations are tested by both techniques.<sup>53</sup> Discretionary tests are carried out for other pathogens.

<sup>53</sup> Professor Turner – Day 7, pages 24–25

**13.32** New forms of screening are rigorously trialed. A test must be sensitive enough that it is going to be worth doing in the first place but has a specificity level that is manageable without unnecessarily deferring large swathes of people.<sup>54</sup> When screening large numbers of healthy people, the false positive group far outweighs the true positives, so the positive predictive value (the number of true positive results amongst the 'positive calls') of the initial screening test is very poor from that point of view. Normally, there should be at least one kind of confirmatory assay, based on a different platform or technology to the original test, since otherwise there would be no way of sorting out the false positives and the true positives. In addition, legally the test has to be CE marked,<sup>55</sup> under the In Vitro Diagnostics Directive<sup>56</sup>, which means it can be marketed in the European Union and, therefore, in this country.<sup>57</sup>

**13.33** Samples which are initially reactive on screening are subjected to a hierarchy of very sensitive further tests. This series of tests is made as sensitive as possible to avoid missing people with infection. The aim is to achieve a low false negative result. That, in turn, creates a risk of more false positives. So, typically, in the modern screening, with third or fourth generation tests reflecting much refinement of technology over the last 10 or 20 years, about two per cent of donations have been found to be reactive on initial screening for one or other marker. These samples are withdrawn prior to use. The sample is then tested again twice using the same assay. About 90% of those are repeat reactive negatives, pointing to a system problem in the initial test. Perhaps only about 0.02% are repeat reactive positive at the second stage. It is not concluded even then that the patient has the infection. Rather, at that stage the donation is quarantined for much more detailed examination; samples are sent to a reference laboratory, where a whole series of different tests, based on different kinds of platforms and technology, are applied to try to establish whether or not there is a true positive result. Again, in general terms, around 10% of those repeat reactive samples turn out to be true infections and the other 90% tend to be technical artefacts (an artificial effect introduced by the technology used). The procedure, as described, now ensures that donors are informed of an infection only when the SNBTS is absolutely certain that the diagnosis is correct.<sup>58</sup> The procedure described protects the patient recipients of blood or blood products without exposing the donor to unnecessary anxiety.

**13.34** This highly sophisticated system has developed rapidly over the last 20 years. Throughout the material part of the reference period, however, the technology underlying the screening tests available was both less sensitive and less specific. There is no basis in the evidence for concluding that, in general, the best available methods of screening were not used as they became available but it is important to note the steps that have been taken to avoid transmission of infection in the course of modern transfusion practice and the treatment of coagulation disorders.

### *Transmission of Hepatitis C and risk of repeat infection*

**13.35** From 1991, when screening of blood became universal practice in the UK, transfusion of blood and blood components and the infusion of blood products have not been associated with the transmission of Hepatitis C to any material extent. In the

<sup>54</sup> 'Sensitivity' is a function of the test's ability to capture all cases of infection with the target pathogen. 'Specificity' is a function of the test's ability to identify only the target pathogen.

<sup>55</sup> CE marking is a manufacturer's declaration that a product meets the requirements of relevant EU directives.

<sup>56</sup> 98/97/EC of October 1998

<sup>57</sup> Professor Turner – Day 7, page 28

<sup>58</sup> Ibid pages 26–27

case of blood products used to treat coagulation disorders, largely retrospective research demonstrated that there had been almost 100% infection with the concentrates that were available before effective virus inactivation began in the mid-1980s, whether commercial materials or the products of the UK public service (NHS) fractionators were used.<sup>59</sup>

**13.36** In the case of blood products, the risk of transmission of blood-borne viruses was related to the number of infective donors contributing to a particular batch and to the severity of the patient's condition requiring coagulation factor therapy and therefore the number of infusions required. The very large number of donors contributing to the plasma pools made the prevalence in the general population almost irrelevant.<sup>60</sup>

**13.37** Other means of transmission raised different issues, such as the relevance of the level of concentration of virus in the source blood and the risk of sexual and neonatal transmission.<sup>61</sup> Hepatitis B is much more readily transmitted sexually than Hepatitis C. Similarly, Hepatitis B is more easily transmitted in the course of surgical procedures, through the perforation of gloves for example. In each case this is due to the concentration of virus in the source blood. The levels that are typically found in Hepatitis B are around  $10^7$  to  $10^8$  (10 million to 100 million) virus particles per millilitre. At those levels, neonatal and sexual transmission is seen fairly frequently. In a normal HCV infection a typical concentration may be  $10^5$  (100,000), or  $10^6$  (a million) virus particles per millilitre. At those levels, it is unusual for either sexual or neonatal transmission to occur.<sup>62</sup> The figure cited in the literature for sexual transmission is 5%. However, Professor Thomas did not think that, in testing spouses, he had ever found a positive case, with the exception of cases of co-infection with HIV where the rate of HCV replication was higher (by one or two logs) and the level of viraemia was relatively high. (The Inquiry identified one such case, the witness given the pseudonym 'Laura'. See Chapter 6, paragraphs 6.228–6.277.)

**13.38** Comparison with Hepatitis A and Hepatitis B gave rise to misconceptions about NANB Hepatitis/HCV which were only dispelled during the 1990s when knowledge of the biology and immunology of HCV developed. Patients who had an attack of Hepatitis A or an acute attack of Hepatitis B and recovered, as indicated by the normalisation of liver enzymes (ALT levels), and the appearance of antibodies indicating immunity (anti-HAV, anti-HBV), had cleared the virus from their bodies and would not be infected again. So when, after a putative attack of NANB Hepatitis, the patient's ALT fell to within the normal range, it was initially assumed that the person had cleared the virus, had acquired immunity and would not be infected again. This turned out to be wrong for two reasons. First, many patients with 'indolent' (apparently benign) NANB Hepatitis/HCV infection had intermittently normal liver enzyme levels but were still harbouring the virus and could still develop significant ill health from it. Secondly, it was realised after the discovery of the HCV antibody that, unlike anti-HAV or anti-HBV, anti-HCV did not indicate immunity to further HCV infection, particularly by HCV with a different genotype. Professor Thomas described this as 'an anomaly in virology'.<sup>63</sup>

<sup>59</sup> Professor Thomas – Day 52, page 76; Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1077. And see, for example: Yee et al, 'The Natural History of HCV in a cohort of haemophilic patients infected between 1961 and 1985', *Gut*, 2000: 47: 845–851 [LIT.001.4318].

<sup>60</sup> Professor Thomas – Day 52, pages 84–85 and pages 89–90; Fletcher et al, 'Non-A, non-B hepatitis after transfusion of factor VIII in infrequently treated patients', *British Medical Journal*, 1983; 287 [LIT.001.0239]; Kernoff et al, 'High Risk of Non-A Non-B Hepatitis After a First Exposure to Volunteer or Commercial Clotting Factor Concentrates: Effects of Prophylactic Immune Serum Globulin', *British Journal of Haematology*, 1985; 60: 469–479 [LIT.001.0800]

<sup>61</sup> See comments on mini transfusion of neonatal infants below at paragraph 13.72.

<sup>62</sup> Professor Thomas – Day 52, page 77

<sup>63</sup> *Ibid* page 83. (See also Chapter 8, *Knowledge of HIV/AIDS Now*, paragraph 8.23 – exposure to HIV does not provide subsequent immunity to that virus either).

**13.39** So, during the 1970s and 1980s, when an individual haemophilia patient was found to have a 'second infection' (often merely a period of months during which ALT levels in the blood became elevated), haemophilia doctors thought that it was probably caused by a second, quite different virus, when in fact it was often the original HCV infection resurfacing in the form of raised ALT levels. It is now also believed that the same individual can acquire second, third and further infections after recovering from a first infection with Hepatitis C. In some haemophilia patients several genotypes and subtypes of HCV have, albeit rarely, been identified in the same individual.<sup>64</sup>

### **Developing perception of the severity and natural history of NANB Hepatitis/Hepatitis C liver disease**

**13.40** Despite significant developments in knowledge, the natural history of HCV is still unclear and tends to be complicated by other factors.<sup>65</sup> The changing perceptions of the severity of NANB Hepatitis/HCV over time are traced in greater detail in Chapters 14–16, *Knowledge of Viral Hepatitis 1–3*. In this chapter it is necessary only to identify some milestones along the way as markers that may be of assistance in interpreting the statements of patients and their relatives.

**13.41** Until the end of the 1970s, the generally accepted view was that NANB Hepatitis was, clinically, relatively unimportant. By 1981 Professor Sheila Sherlock would write in the sixth edition of her highly respected textbook, *Diseases of the Liver and Biliary System*, that the prognosis of NANB Hepatitis was 'uncertain but probably benign'.<sup>66</sup>

**13.42** However, at the time of publication of the sixth edition of Professor Sherlock's book, Dr May Bamber and others, including Professor Sherlock and Professor Thomas, were already engaged in studies based on biopsy findings which demonstrated that patients with chronic NANB Hepatitis had disease that covered the whole spectrum of acute and chronic hepatitis, including cirrhosis.<sup>67</sup> That study was also published in 1981. In retrospect, it marked the beginning of a significant change in expert opinion. US research published in 1982 pointed in the same direction.<sup>68</sup>

**13.43** Research into the progression to serious liver disease in Hepatitis B, relying on biopsy findings, had enabled the development of prognostic indicators relating to the pattern of inflammation observed in the liver tissue. Chronic persistent hepatitis, considered to have a very benign prognosis, was related to inflammation in the portal tracts. Inflammation that extended out into the periportal area – chronic active hepatitis – was associated with the risk of subsequent development of cirrhosis. Inflammation spread evenly in the hepatic lobule (chronic lobular hepatitis) was associated with a benign prognosis. Bridging fibrosis, in which fibrous tissue was found between the portal tracts and the central veins, or between the portal tracts themselves, was an indication of the onset of cirrhosis.<sup>69</sup>

<sup>64</sup> Professor Thomas – Day 52, pages 83–84

<sup>65</sup> Professor Hayes – Day 78, pages 79–80

<sup>66</sup> Sherlock, S. *Diseases of the Liver and Biliary System*, 6th edition 1981

<sup>67</sup> Bamber et al, 'Clinical and histological features of a group of patients with sporadic non-A non-B hepatitis', *Journal of Clinical Pathology*, 1981; 34: 1175–1180 [LIT.001.0759]

<sup>68</sup> Koretz et al, 'Non-A, non-B post-transfusion hepatitis: disaster after decades?', *Hepatology*, 1982; 2: 687 [LIT.001.3738]; Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1079–80

<sup>69</sup> Professor Thomas – Day 52, pages 116–118

**13.44** It was initially assumed that the prognostic indicators for NANB Hepatitis/HCV infection were the same as for Hepatitis B.<sup>70</sup> In the early biopsies carried out in patients with NANB Hepatitis, the findings were of chronic persistent or chronic lobular hepatitis and the supposition was that they were unlikely, as a matter of probability, to progress to serious sequelae. Initially, biopsies were performed on putative NANB Hepatitis patients who had biochemical indications of a steep rise in ALT before it returned to normal.<sup>71</sup> It was on the basis of indications from these procedures that it was inferred initially that NANB Hepatitis was a benign prognostic disease, partly because, as already noted at paragraph 13.7, these were the minority of individuals who were likely to recover fully and not develop chronic illness.<sup>72</sup> In retrospect, the widely held supposition that chronic persistent and chronic active hepatitis would follow the same clinical course in Hepatitis C as in Hepatitis B, was wrong.<sup>73</sup>

**13.45** A Sheffield study by Dr David Triger and others in 1978 showed cases of cirrhosis in haemophilia patients infected with NANB Hepatitis. There was case selection towards the adverse end of the disease spectrum, however, confounding the picture that emerged.<sup>74</sup> Additionally, the basic characteristic of biopsy, that it targets a minute piece of the liver, gave rise to sampling errors.<sup>75</sup> Further, there were other factors that might have contributed to the progression of disease, such as age at infection, the duration of infection, obesity and alcohol use, which were not necessarily reflected in biopsy findings or properly understood at that time.<sup>76</sup>

**13.46** The 1981 study by Bamber and colleagues related to 12 patients, both transfusion patients and patients without a transfusion history, who were diagnosed on serological grounds as having NANB Hepatitis infection. No haemophilia patient was involved. Some patients had cirrhosis; some had chronic active hepatitis with piecemeal necrosis; one had portal-systemic encephalopathy associated with cirrhosis and severe liver dysfunction. There was evidence of fatty change and bile duct damage. The findings were an affirmation of the work of Dr Triger's Sheffield group, which had previously been controversial.<sup>77</sup> By the 8th edition of her book in 1989, Professor Sherlock had changed her stance: she wrote in that edition that 20% of infected individuals would develop cirrhosis over 20 years and that after 30 years the proportion would increase progressively.<sup>78</sup>

**13.47** Professor Thomas emphasised that doubt remained:

[S]ome would say, even now, we do not really know the factors that determine the rate of progression and, for instance, in Italy Hepatitis C has a much worse prognosis to what you see in northern Europe ... and ... that's arguably related to all the other factors ... how much alcohol you take, the genetic factors, whether there is co-infection with other viruses, all manner of things.

So I don't think this uncertainty about the natural history that was prevalent between 1978 and 1985 has changed massively. I think we are still wondering:

is it 20 per cent or 40 per cent that will develop cirrhosis? All we can deduce from these studies is that some people in the context of normal life ... where we eat and drink ... some people have severe liver disease. But how many, that's an open question still, because none of the studies ... are statistically significant. There isn't a large enough sample of unselected cases.<sup>79</sup>

**13.48** As noted above, once a patient already has cirrhosis, it does not disappear even when the causative viral infection is cured. The risk of progression to hepatic decompensation (liver failure) and possible HCC is reduced, however, and the patient is no longer infectious. Cirrhosis does put the patient at risk of liver cell cancer, however. There are patients who had cirrhosis prior to treatment who have undergone a sustained viral response and are cured, virologically speaking; some of them have nonetheless gone on to develop primary liver cell cancers.<sup>80</sup> In current practice, once a person has been identified as having cirrhosis, he or she will be monitored by ultrasound and an alphafetoprotein test every six months in the hope of identifying tumours when they are small and more treatable.<sup>81</sup> The patient will also be regularly monitored for varices by upper gastro-intestinal endoscopy. In this group clinicians do not anticipate a cure of the patient's overall condition because they are still at risk of severe complications.

**13.49** The position of a haemophilia patient is complicated by his primary condition. Thus, in terms of the overall effects of their underlying illness on quality of life metrics, the starting Quality of Life score would be unlikely to be the score typical for a member of the general public because of the clinical manifestations of haemophilia itself and possible associated psychological factors. There will also be continuing concern whether the condition has been dealt with.<sup>82</sup> Professor Thomas said:

[I]t's a very complicated situation really. There is the pre-treatment problems. They may have additional problems, other worries, financial worries, you know, and doctors tend to find reassurance, since they are making very difficult decisions ... if there is something objective they can measure, which is the presence or absence of the virus by techniques which are exquisitely sensitive really. And if, when you do that, you come up with a logic, something that you can understand -- when the virus goes down the patient feels better; when it goes up again, he feels unwell -- all that reassures the doctor that he is probably measuring something that's relevant.<sup>83</sup>

**13.50** By contrast, he suggested, Quality of Life measures – before and after 'successful' treatment for HCV in haemophilia patients – are much more complex.

**13.51** Now, over 20 years after the identification of HCV as the 'culprit' for almost all NANB Hepatitis infections, perceptions have changed. It has recently been estimated that, in the USA at least, the cohort of HCV-positive individuals (the total HCV-positive population) peaked around 2001 and will decline slowly over the following 20 years. Recently, Dr Gary Davis and colleagues observed that, bearing in mind that the prevalence of HCV infection in the population increased very quickly in the 1970s and 1980s (the first part of the HCV 'cohort'), by 1989 cirrhosis is thought to have occurred in about 5%

of all cases of chronic Hepatitis C, in 10% of all cases by 1998 and 20% by 2006. It was projected to have risen to 25% in 2010 and to be likely to rise to up to 37% in 2020 and 45% in 2030.<sup>84</sup>

### Clinical and other features of Hepatitis C infection

**13.52** This section notes clinical and other features associated with Hepatitis C infection in the UK. That excludes some complications found elsewhere. Marked geographical differences occur. For example, as noted above at paragraph 13.18, there is a high prevalence of HCV-positive patients in Mediterranean countries with non-Hodgkin's B Cell Lymphoma (a cancer of the lymphoid system) but there is no epidemiological evidence for the virus being involved in non-Hodgkin's B Cell Lymphoma in northern Europe.<sup>85</sup>

**13.53** In the early 1970s, jaundice was thought to be an important diagnostic feature of hepatitis generally and, from the mid-1970s, of NANB Hepatitis in particular. However, jaundice is rare in Hepatitis C infection.<sup>86</sup> Fulminant (rapidly progressing) hepatitis, indicative of liver failure, is very rare. Less than a fifth of cases involve jaundice. Professor Thomas emphasised that the rareness of jaundice was quite important because of the impact it had on the early lack of understanding of the infection. (See Chapters 13–15, *Knowledge of Viral Hepatitis 1 to 3.*)

**13.54** Two factors contribute to the severity of HCV infection. The first is the size of the inoculum (the amount of virus with which the patient is initially infected) and, resulting from that, the rate of spread of infection through the liver and the number of liver cells infected. The second is the speed of response of the immune system. If the immune response is very quick, there is rapid clearance of the infected liver cells, faster than the rate at which liver regeneration can replace the infected cells, and severe and more acute symptoms follow.<sup>87</sup>

**13.55** Clinical features common in acute hepatitis include influenza-type symptoms with malaise, myalgia (muscle pain), arthralgia (joint pain), anorexia (loss of appetite) and nausea and there may be mild pyrexia (elevated temperature). These may be followed by the biochemical features of hepatocyte necrosis (liver cell death) as the immune system attempts to clear the virus-infected liver cells. Transaminases (liver enzymes) increase in the blood as they are released from dying liver cells. An increase in serum bilirubin (described below) may occur. In such cases, the patient's urine becomes dark, stools become pale, and the patient may become jaundiced and develop itching.

**13.56** Where jaundice does occur in Hepatitis C, it lasts usually one to four weeks and heralds improvement in most cases, though a feeling of malaise and of being generally unwell may last many months.<sup>88</sup> Jaundice occurs when the liver cell mass is reduced, so that bilirubin can no longer be excreted. Bilirubin is a product of the red blood cells of the body, formed from broken-down haemoglobin. It is excreted through the liver and, because of reduced liver cell mass and also the fact that the liver cells swell, inhibiting the passage of the bilirubin into the bile ducts, there is obstruction of bile flow and cholestasis

<sup>84</sup> Davis et al, 'Aging of Hepatitis Virus (HCV)-infected Persons in the United States: a Multi-cohort Model of HCV Prevalence and Disease Progression', *Gastroenterology*, 2010; 138: S13 – S21 [LIT.001.4046]

<sup>85</sup> Professor Thomas – Day 53, pages 74–75

<sup>86</sup> Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1080.

<sup>87</sup> Professor Thomas – Day 53, pages 10–12

<sup>88</sup> Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1080

occurs: bile cannot flow from the liver to the duodenum, the first portion of the small intestine. Both factors, reduced liver functioning cell mass and reduced ease of flow of bilirubin into the bile ducts, contribute to a rise in bilirubin in the blood, and the eyes, and sometimes also the skin, become yellow.

**13.57** Jaundice does not happen in most cases of Hepatitis C because the initial 'insult' (damage) to the liver is less severe than, for instance, in Hepatitis A or B, when a larger proportion of the liver cells is infected and destroyed by the immune system as the infection is cleared.<sup>89</sup> Post-transfusion screening for jaundice therefore picked up only a small proportion of cases of NANB Hepatitis/HCV infection. This led to differing perceptions among doctors. While transfusionists in Scotland around 1980 believed that post-transfusion NANB Hepatitis was rare, on the basis of low reporting of jaundice, haemophilia centres saw persistent mild liver blood test abnormalities as very common, but probably of little importance.

**13.58** There are also extra-hepatic manifestations of infection.<sup>90</sup> The most readily understood of these are renal and dermatological and related to 'cryoglobulinemia', a condition in which the Hepatitis C virus forms an immune complex with associated antibodies and circulates in a patient's blood. When the blood cools in circulation, the complex precipitates out of suspension and this 'cryoprecipitate' can stick in small blood vessels, particularly in the kidney, which sometimes results in renal dysfunction.

**13.59** Dermal complications can be related to those immune complexes being deposited in the capillaries or small arterioles in the skin, often on the lower limbs, leading to the formation of small, painful and uncomfortable black nodules: a condition known as cryoglobulinaemia.<sup>91</sup> The nodules look like purpura but are actually thrombosed blood vessels, where the cryoglobulins, the immune complexes, have become stuck in the small blood vessels of the leg. The lower leg is more likely to be affected because, as the circulation is slower there, the lower legs are colder than the upper limbs or trunk and precipitation is more likely.

**13.60** Other dermatological features of HCV infection are associated with the problem called 'lichen planus' which manifests in rashes on the skin. Professor Thomas thought there was really no idea, as yet, as to why the infection should be associated with lichen planus.<sup>92</sup>

**13.61** Many of the flu-like signs and symptoms, which arise both in acute hepatitis (when the body naturally produces interferon) and in the course of treatment with Interferon for chronic infection, were noted in a 2006 study by Dr Mark Wright and others (including Professor Thomas).<sup>93</sup> This gave rise to a question as to whether the symptoms were caused by treatment rather than by HCV itself.

**13.62** Professor Thomas thought that some auto-immune diseases found in association with HCV infection, such as rheumatoid arthritis and autoimmune thyroiditis, were likely

---

<sup>90</sup> Ibid pages 73–76

<sup>91</sup> Ibid pages 76–77

<sup>92</sup> Ibid page 74

<sup>93</sup> Ibid pages 34–36

to result from a genetic predisposition common to those conditions rather than a causal connection with HCV, but agreed that treatment would exacerbate those conditions in those with a genetic predisposition to them.<sup>94</sup>

**13.63** Using validated methods to assess mental and physical wellbeing, it has been shown that Hepatitis C patients have generally reduced mental and physical wellbeing, of a comparable level to what might be seen in diabetes (another chronic disease), for example.<sup>95</sup> Since such neurological and psychological difficulties may occur without serious liver disease, attributing a cause for such symptoms can be difficult in an individual case. Severe liver disease may be the cause, since with liver failure there may be an accumulation of nitrogen compounds derived from the gut which leads to hepatic encephalopathy (confusion, cognitive impairment and lethargy). In some patients, mental acuity is blunted by past use of recreational drugs. If those two are excluded, the third case, what is called 'mental fog' in the USA, represents infection of the central nervous system with HCV.<sup>96</sup>

**13.64** Although the association of HCV infection with some of these features of quality of life and brain function is based on 'soft' evidence, these are precisely the symptoms and signs that many patients have complained of in statements provided to the Inquiry. Such symptoms have been under-appreciated in the past but the bulk of evidence now strongly supports an association. Dr Karin Weissenborn and colleagues have recently characterised the well-documented neuropsychological effects of HCV infection on the brain as follows:

A reduction in health related quality of life, chronic fatigue, depression and cognitive decline are characteristic complaints of HCV-infected patients even in the absence of significant liver disease.<sup>97</sup>

**13.65** In chronic hepatitis, the measure of severity is related to the rapidity of progression but Professor Thomas' evidence revealed that there is still some uncertainty about causal relationships. He thought that the rapidity of progression (as well as the severity of the infection, as noted in paragraph 13.54) would be related to the size of the initial inoculum but the picture was complicated by that the interaction of other variables, such as co-infection with HIV, immunosuppression due to medication and the rate of reproduction of the virus.<sup>98</sup> In relation to the rate of progression of the disease, he said:

In chronic hepatitis C the presence and quantity of virus in the blood stream is determined by reverse transcriptase polymerase chain reaction (rt-PCR). Levels fluctuate from month to month and tend to be higher in immunosuppressed people such as those infected with HIV. The level of viraemia in HCV does not appear to determine the rate of progression to liver cirrhosis in the non-immunosuppressed. Levels of transaminases also fluctuate over time. The presence of normal transaminases does not exclude significant liver fibrosis. The rate of progression to cirrhosis varies among individuals chronically infected with HCV. Different sub-groups of patients progress at different rates. Major risk factors have been identified: male gender, excess alcohol and age [over] 50 at acquisition.<sup>99</sup>

<sup>94</sup> Ibid pages 75–76

<sup>95</sup> 'Life score metrics' may be made more complex by background issues affecting the patient which, in the opinion of neurologists, make it difficult to evaluate residual symptoms after an acute illness.

## Factors which influence the outcome of HCV infection

**13.66** Professor Thomas agreed generally with the conclusions of the *Bassendine Review of Natural History of HIV Infection* relating to HCV infection.<sup>100</sup> The Review stated:

The proportion of patients who develop chronic HCV infection may be determined by many factors. These include age at time of infection, gender, ethnicity, presence of symptoms during the acute infection, genotype, immunosuppression and HIV.<sup>101</sup>

**13.67** Professor Thomas expanded on some of these matters.<sup>102</sup> There is consensus that certain factors do influence outcome. Others are postulated but are not confirmed or sustained by other studies. Some factors are not confirmed because they are not direct determinants: they are correlates of something that is a direct determinant. Male gender indicates a more severe outcome in chronic infection, in all studies. Ethnicity plays a role. That is now known to be related to the frequency in which the IL28 genetic polymorphism is found in different ethnic groups. Most people are offered treatment and the mechanism of the response rate to Interferon, which will determine whether the patient does well after infection, has a different frequency in different ethnic groups, again due to differences in the prevalence of the immune system's recognition proteins.

### *Age at time of infection*

**13.68** Age at the time of infection is agreed to be a contributory factor in the progression of HCV infection. Above about 50–60 years of age, there is a deterioration of the body's capacity to regenerate, whether it is to replace scar tissue resulting from a simple cut or to replace liver cells killed by the immune response to HCV infection. There is a change in the gradient of the curve measuring progressive liver damage. If an individual is infected after this change, progression is more rapid. After discussion with Professor Oliver James, Medical Assessor to the Inquiry, Professor Thomas said:

[B]oth with Hepatitis B and Hepatitis C, if you get an acute hepatitis in your later years, let's say 60, then there is a syndrome called "failure to regenerate". You ... have a wave of destruction of liver cells, which is essential for part of the recovery process because the cells contain the virus, you have to destroy them to get rid of them, you are then producing antibody to stop the virus moving into the neighbouring cells, but in addition, the neighbouring cells have to regenerate to replace the ones that have been killed.

So there are four components, if I could summarise it. There is the number of infected cells; there is how quickly they are being destroyed, which is dependent on the cellular immune response; there is the production of antibody, which is going to be important to stop the virus released from the destroyed cells to infect the cells next door; and the last thing is you are down on the number of liver cells that you have, because of the ones that have been destroyed, so you are dependent on the liver regenerating. So if any of those components result in a situation of a [reduction] in liver cell mass, then you will ultimately enter liver failure.<sup>103</sup>

<sup>102</sup> Professor Thomas – Day 53, pages 15–17

<sup>103</sup> *Ibid* pages 27–28

**13.69** The Inquiry heard evidence from a number of witnesses who added to its understanding of the relevance of age. Dr Graeme Alexander, Consultant Haematologist at Addenbrooke's Hospital, Cambridge, drew on information from the national HCV look-back study<sup>104</sup> of which he was Chairman. He said that the majority of people who were young at the time of infection did not progress to cirrhosis at all.<sup>105</sup> In the case of patients who were relatively young at the date of infection who did progress to cirrhosis, the period from that stage to the development of end stage liver disease would be of the order of 10 years or more. Both the period of evolution from infection to cirrhosis and the period of evolution from cirrhosis to death were shorter in people who were older when they were first exposed to HCV.<sup>106</sup> Publications drawing attention to the importance of age first began to appear in about 1997; before that time, the natural history of Hepatitis C in older patients had been misunderstood. Most clinical experience had been based on an understanding of NANB Hepatitis in patients, most of whom died from the disease that had led to intervention in the first place. A diagnosis of NANB Hepatitis was simply the identification of abnormal liver test results that arose after transfusion, for which there were many possible explanations. The view of what NANB Hepatitis did to patients was artificially skewed. It was not until the introduction of testing for HCV in 1991 that it began to be realised that there were many people who had a disease that was very different from the disease as previously understood. In the clinical context there was not much that could be done. The report on Mr Laing, referred to the Inquiry in Term of Reference 6, provides clear evidence of a high rate of progression in an older man with no aggravating factors. (See Chapter 7.)

**13.70** Other evidence supported the view that, among younger patients infected with HCV with no other aggravating factors, progression may be slow and with a mild outcome for considerable periods of time. Long-term follow-up studies over a period of 35 years have been reported of Italian children given HCV-infected 'mini-transfusions' from a single donation at or about the time of birth.<sup>107</sup> In Italy, during the 1960s, mini-transfusion of blood or plasma was a frequent treatment of under-weight or pre-term newborn children. Transfusions of blood from a single donor later found to be HCV-infected were given to 31 children, all of whom were 35 years of age at the date of the report. At enrolment into the study in 1998, 18 were found to have HCV antibody and 16 were HCV-RNA positive. Eleven of the viraemic patients had liver biopsies. Nine of the 11 biopsies showed no fibrosis or mild portal fibrosis, and two had either discrete (Ishak's stage 3) or marked (Ishak's scale 4) fibrosis. None of the individuals was aware of having been transfused during the first weeks of life and none reported a history of jaundice or had signs or symptoms of hepatitis. For all practical purposes, the infections had been silent for 35 years.

<sup>104</sup> The purpose of look-back was to trace NHS patients who had received blood, blood components or blood products derived from donations by donors who tested positive for Hepatitis C antibodies after 1 September 1991, when screening was introduced, and who had previously donated blood which was found by retrospective testing also to have been infective. See Chapter 36, *An Investigation into the Steps Taken to Identify the Individuals Who Were Infected*.

<sup>105</sup> Day 4, pages 35–36

<sup>106</sup> *Ibid* page 36

<sup>107</sup> Casiraghi et al, 'Long term outcome (35 years) of Hepatitis C after acquisition of infection through mini transfusions of blood given at birth', *Hepatology*, 2004; 39: 90–96 [LIT.001.4027]

**13.71** Dr David Mutimer (Consultant Hepatologist, The Queen Elizabeth Hospital, Birmingham) described his experience with relatively young people in the Birmingham area.<sup>108</sup> His data had been derived from a large population of patients who were infected with Hepatitis C. The median time from infection to cirrhosis was thought to be about 30 years: half of the patients had developed cirrhosis at 30 years after infection and the other half had some lesser degree of liver damage at that stage. What distinguished the people who progressed more quickly to cirrhosis was only partly understood. Some factors had been identified but others were not known. The study showed that men progressed more rapidly than women. It had also been established that alcohol would accelerate the progression to cirrhosis. In that cohort it was very rare to see cirrhosis within 10 years of infection in that cohort and it was uncommon to see it within 20 years of infection, unless there were aggravating factors.

### *Duration of infection*

**13.72** Duration of infection is a factor. In the USA, much Genotype 1 infection occurs after blood transfusion, where the onset of infection is known and therefore doctors can work out the duration of the infection, sometimes 20 years later. In Genotype 3, infection occurs mainly in the Asian population and there, in large group studies, it is apparent that a great many of the patients are infected in infancy and the infection turns out in later life to be apparently more severe than Genotype 1. That is probably related to the fact that the reference point at which people present with significant liver disease is 40 years after the onset rather than perhaps 15 or 20 years. Assessing the role of genotypes is frequently confounded by being unable to determine the time when infection was acquired, hence the duration of infection also remains unknown. Immuno-suppression and HIV infection are well documented as being associated with more severe HCV disease. In the haemophilia population, that has clearly been evident, in that those with co-infection have, in the main, had a higher liver-related mortality than those who have had Hepatitis C alone.

**13.73** Haemophilia patients present particular problems of analysis. The level of virus might have been constantly topped up by successive infusion of infected coagulation factor concentrates, as indicated by the observation that some patients had several genotypes of the virus present. In their cases, as distinct from transfusion patients, there was the problem that the date when the first infective dose was administered might be the 'unknown variable'.<sup>109</sup> Successive biopsies over a period of years gave data of developing fibrosis on which clinicians could project the progression of the disease and advise on the need for treatment in the case of an individual patient, essentially to stop progression before Ishak's stage 6 (cirrhosis) but the pattern was variable and generalisation difficult.<sup>110</sup> Furthermore, multiple biopsies in haemophilia patients are hazardous and seldom indicated.

### *Infection with more than one genotype of HCV*

**13.74** The possibility of infection with more than one genotype of HCV raises a question whether that factor of itself increases the rate of progression of disease. Professor Thomas did not know of any data to suggest that but thought that confronting a wider range of infection might well present a greater challenge to the immune system.<sup>111</sup>

## *Aggravating factors*

### Alcohol

**13.75** There are some well-recognised aggravating factors that affect the outcome of HCV infection, though the evidence available to the Inquiry was not uniform. In particular there were conflicting views relating to alcohol. Professor Thomas took the more extreme view of the damaging effects of alcohol in patients with Hepatitis C. He contrasted Hepatitis B and Hepatitis C and his evidence was that alcohol affects the progression of Hepatitis C but not Hepatitis B. Data on liver damage seen in Hepatitis B cases where there is evidence of consumption of alcohol suggests that the liver damage found is the summation of the damage due to alcohol and what is due to the disease: the alcohol does not 'synergise' with Hepatitis B. He said that it is now accepted that alcohol increases the level of replication of Hepatitis C and, as a consequence, the liver damage seen in a patient with Hepatitis C who is, in addition, taking significant amounts of alcohol is greater than the sum of the damage due to the alcohol and the Hepatitis C: the two factors are synergistic in HCV but not in HBV.<sup>112</sup>

**13.76** In Professor Thomas's view, the synergistic effect of alcohol was established around 2004–05 as a result of studies by Dr Ralf Bartenschlager, using a system of cells which supported replication of a model of HCV. In looking at a variety of factors that altered the effectiveness of replication, the synergistic effect of alcohol was observed.<sup>113</sup> Lifestyle advice, particularly relating to alcohol consumption, had long been common but was given added emphasis as a result of this finding. On this approach, the risk of accelerated liver damage in chronic HCV infection may be associated with quite moderate consumption: it is not limited to groups commonly recognised as alcoholics or those who would be described popularly as 'drunks' or who exhibit functional deficiencies in their ordinary lives.<sup>114</sup>

**13.77** For this reason, Professor Thomas said:

[B]efore we had ways of treating patients with Hepatitis C, one important thing to say was that you can slow down the progression of your Hepatitis C if you reduce your alcohol intake, and the ideal scenario would be that you would be abstinent from alcohol.<sup>115</sup>

**13.78** Professor Hayes adopted a different stance. In his unit, patients were generally advised to abstain entirely from alcohol if they had cirrhosis, but if their liver disease was short of cirrhosis then drinking within sensible limits of 21 units a week for a man and 14 units for a woman was considered safe (the same recommended safe limits of alcohol as advised for members of the public generally).<sup>116</sup> He did not think that advice based on that view had changed much over time.<sup>117</sup> He was examined on the advice contained in the Scottish Intercollegiate Guidelines (2006) on the management of Hepatitis C that:

Even moderate amounts of alcohol (within government recommended guidelines) have been associated with increased liver fibrosis compared to those who abstain.

<sup>115</sup> Professor Thomas – Day 52, page 18

<sup>116</sup> Professor Hayes report [PEN.018.0240] at 0243

<sup>117</sup> Professor Hayes – Day 78, page 69

Patients with [chronic Hepatitis C] should be advised that drinking alcohol (even in moderation) can accelerate progression of liver disease.<sup>118</sup>

**13.79** He thought it debatable whether drinking alcohol in moderation created a risk of progression of chronic Hepatitis C in the mild and moderate categories.<sup>119</sup> He had never been persuaded by the evidence and it had not been drawn to his attention that drinking within the recommended limits would accelerate liver disease.<sup>120</sup>

**13.80** Dr Mutimer's experience in Birmingham provided a practical indication of the impact of alcohol. In his experience, the majority of patients with Hepatitis C requiring liver transplants had been infected in their late teens or early twenties and many would have had a history of significant alcohol consumption. He did not suggest that dependency, or the excesses associated with alcoholism, were prerequisites.<sup>121</sup> The average age at which liver transplant was necessary was 55. Dr Andrew Bathgate's findings in that respect were broadly consistent with Dr Mutimer's broadly based investigations.<sup>122</sup>

**13.81** It is not yet possible to resolve completely the issue of the extent to which alcohol consumption affects progression of HCV-related liver disease. The scientific basis for Professor Thomas's evidence is strong. Professor Hayes' clinical experience is extensive. Dr Mutimer's evidence correlated advanced liver disease at a relatively early age with significant alcohol consumption in the late teens or early twenties. In general terms it would appear not unreasonable to conclude that the consequences of consumption of alcohol would depend on a range of factors, including the quantity consumed, the regularity of the practice, the duration of the practice and the patient's liver disease profile.

## Smoking

**13.82** The *Bassendine Review* listed smoking tobacco as an aggravating factor.<sup>123</sup> Recent studies have suggested that heavy smoking generally increases both liver fibrosis and inflammatory activity in chronic HCV infection, supporting the Bassendine finding.<sup>124</sup> Initially, French researchers suggested that smoking cannabis might also stimulate fibrosis. It is now known that there is indeed a mechanism by which cannabis causes fibrosis: some cells have cannabinoid receptors to which the cannabis molecule binds and the cells which stimulate fibrosis also have those receptors.<sup>125</sup>

## Obesity

**13.83** Obesity is an aggravating factor. Professor Thomas said:

[I]t's becoming increasingly the case that three things are operating adversely in many patients. One is Hepatitis C itself. Second is, as we have mentioned, alcohol, and whether there is obesity, which is associated with deposition of fat in the liver. So what's becoming clear with all of these so-called insults to

the liver is that the accumulation of fat, which ultimately may burst the liver cells, is bad news in terms of creating a risk of fibrosis.

... .

And those three things that I have mentioned, alcohol and obesity and certain genotypes of Hepatitis C, all cause an accumulation of fat in the liver. And the genotype that is most involved in the accumulation of fat is genotype 3.<sup>126</sup>

### Co-infection with Hepatitis B

**13.84** Co-infection of Hepatitis C with Hepatitis B is a significant complication. The risks associated with HBV infection vary with age. Children infected at birth, or up to about two years of age, have a 95–100% risk of becoming chronically infected, with a risk of progressive liver disease. In contrast, after two years of age, right through the middle and later years of adult life, 95% of individuals who are infected develop an acute, self-limiting infection and only 5% develop chronic infection. Of those who have a chronic infection and proceed to develop cancer, 30% (almost all of whom acquired infection in early childhood) will develop a cancer before the stage of cirrhosis, and 70% will already have had cirrhosis before the cancer is developed.<sup>127</sup> Increasing knowledge of the pattern of developing disease as understood from time to time has an important bearing on patient care, and the need to provide treatment before a cirrhotic stage is reached. In co-infection with HBV and HCV the viruses interact with each other and affect immune response. HCV may inhibit HBV replication and vice versa. Combined chronic Hepatitis B with Hepatitis C leads to more severe liver disease and an increased risk of development of HCC.<sup>128</sup>

### *Do symptoms persist after successful treatment?*

**13.85** A question arose whether there could be 'occult hepatitis', a persistence of symptoms, or 'extra-hepatic manifestations', after the patient had a negative polymerase chain reaction (PCR) test, showing that the virus had been cleared. Professor Thomas explained the position.<sup>129</sup>

**13.86** He said that there could be situations at or within a few months after the end of a period of treatment when the virus could not be detected in the circulating blood but might be present in the liver or in a cell. That had been described in the case of Hepatitis B.<sup>130</sup> However, the extra-hepatic manifestations he had discussed, the renal and dermatological signs and non-Hodgkin's lymphoma,<sup>131</sup> arose without exception where there was continuing viraemia detectable by HCV RNA PCR test systems. In the case of 'brain fog', the majority of the virus was being produced in the liver and the patients had viraemia. Low physical and mental wellbeing scores were not indicative of continuing infection in the absence of viraemia. After a demonstrable sustained viral response (where more than six months after the end of treatment viraemia is undetectable by the most sensitive HCV RNA tests), residual cognitive or other abnormalities are often associated with non-viral related problems: they are not attributable to a continuing 'occult' presence of the virus.<sup>132</sup>

<sup>130</sup> Ibid pages 65–66

<sup>131</sup> As noted in paragraphs 13.18 and 13.52, non-Hodgkin's lymphoma is not associated with HCV infection in northern Europe, but it is relevant to Professor Thomas' opinion.

<sup>132</sup> Professor Thomas – Day 53, pages 69–70

## Investigation and Treatment

**13.87** Up-to-date knowledge of the natural history of HCV infection is clearly necessary for a proper understanding of the witnesses' evidence. In order fully to understand the evidence of patients and their relatives, however, it is necessary to have regard also to some significant developments in the investigation of the infection and in the treatments available.

### *Investigation*

**13.88** From about 1978 doctors used blood tests to monitor haemophilia patients' ALT levels more or less as a matter of course, although it is not clear whether they had a well-developed understanding of why they were doing so. Biopsy changed the course of investigation. As indicated in paragraph 13.42, by 1981 experts, including Professor Sherlock and Professor Thomas, were already engaged in studies of NANB Hepatitis infection based on biopsy findings.

**13.89** Once established in research practice, histology (microscopic examination of samples of tissue) obtained by conventional liver biopsy was thought to be the most reliable way of monitoring the severity of liver disease. The degrees of necro-inflammation (grade) and fibrosis (stage) were key to interpretation and consequent clinical decision-making regarding treatment.<sup>133</sup>

**13.90** Generally, the standard method for performing a liver biopsy is to introduce local anaesthetics to the skin overlying the liver, insert a needle into the organ and remove a small core of liver tissue. An alternative method of removing a tissue sample involves inserting a long needle through a vein in a patient's neck to their liver, with the benefit of ultrasound examination. Professor Hayes described a method used in patients with haemophilia in Edinburgh in the late 1980s which involved inserting a small telescope into the abdomen and then inserting gas to give a view of the liver. This allowed the doctor to see the liver directly and so see the part of the liver from which the biopsy was taken. Although originally biopsies were taken during these procedures, it later became the practice for the liver to be inspected without removing tissue.

**13.91** Liver biopsy carries with it a risk of haemorrhage and even death, the latter risk being about 1 in 10,000. These risks are significantly increased in patients with haemophilia. Liver biopsy of a patient with haemophilia is not straightforward and there are a few examples of fatal outcomes from the standard method.<sup>134</sup> Occasionally a blood transfusion may be required following haemorrhage. The standard method of liver biopsy causes variable pain but it can be extremely painful.<sup>135</sup> The narrative of the experiences of patients illustrates the impact of these biopsy procedures. More recently the non-invasive procedure FibroScan, using transient elastometry to measure liver stiffness, is employed to assess the degree of fibrosis of the liver.<sup>136</sup>

**13.92** Other investigative procedures include endoscopy, used to examine and monitor the patient for upper gastro-intestinal varices. Many patients find the procedure uncomfortable.

<sup>136</sup> SIGN 133: *Management of Hepatitis C* (2013) paragraph 8.2 [LIT.001.5550] at 5571

## Treatment

**13.93** Brief comments on treatment are contained in paragraphs 2.39–2.44 of the Preliminary Report. An excellent national clinical guideline, *Management of Hepatitis C*, has recently been updated by the Scottish Intercollegiate Guidelines Network (SIGN).<sup>137</sup> The oral evidence, particularly the evidence of Professors Thomas and Hayes, has increased the Inquiry's understanding of the topic. An account of progress in the management of patients and in therapy is contained in Chapters 14–16 *Knowledge of Viral Hepatitis 1 to 3*. At this stage it is sufficient to note a few significant developments.

**13.94** Initially, it was remarkably difficult to treat a condition with an unknown cause. After the Chiron discovery, Alpha Interferon was the first drug that looked promising, though some early trials look less than convincing by contemporary standards.<sup>138</sup> It was used by Professor Thomas and his colleagues from about 1989. In terms of sustained viral response, rates varied between 12% and 15%.<sup>139</sup> This proportion may have been even lower among haemophilia patients.<sup>140</sup> The use of Alpha Interferon in a clinical research setting in 1989 was the first step in England in what would be a lengthy process of controlled trials leading to a licence and approval for use; a licence was granted in November 1994 for Alpha Interferon to be used in the treatment of chronic Hepatitis C. Professor Hayes had no recollection of treating anyone with Interferon before 1991. He treated the first few patients in Scotland in 1991 and 1992.<sup>141</sup> He also found that the drug appeared to be effective in clearing HCV in a minority of patients.<sup>142</sup> It was, however, to be some years before the technology was developed that demonstrated benefit even in those patients.<sup>143</sup>

**13.95** The next significant development was the use of recombinant Interferon with Ribavirin, around 1995–96, and then of pegylated Interferon, a longer acting form of Interferon.<sup>144</sup> From the mid-1990s to the early 2000s access to newer treatments was not available outwith clinical trials until the treatments had been approved and licensed.<sup>145</sup> With each stage in development effectiveness improved, from the base level of 10–20% with monotherapy.<sup>146</sup>

**13.96** Professor Hayes also pointed out that, to be eligible to participate in a trial at that period, a patient had to agree to liver biopsy before and after treatment since liver histology was deemed the 'gold standard' by which to measure the effect of treatment on the liver. It was a regulatory requirement.<sup>147</sup> Because of the hazards of liver biopsy in haemophilia, very few haemophilia patients entered the studies and thereby benefited from early access to more effective treatment.<sup>148</sup> Clinically, biopsy was considered not to be a sensible risk for haemophilia patients to take unless it was required in clinical practice.<sup>149</sup> Whilst not being included in a trial might well have been a source of frustration for a patient who was

<sup>148</sup> Ibid pages 54–55

<sup>149</sup> Ibid page 57

aware of a potential new treatment, Professor Hayes considered that not being included in a trial was not 'a major disadvantage'.<sup>150</sup> He gave two reasons for this. First, even if a patient was included in a clinical trial it did not necessarily mean that he received the new treatment, as half of those participating in a trial received the standard treatment and half the new treatment. Secondly, it took about two to four years for a treatment to become available following a trial and Professor Hayes considered that a wait of that duration was not a major disadvantage since the natural history of the condition from the time of infection until it caused symptoms is measured in decades rather than years.<sup>151</sup>

### **Current guidance**

**13.97** The current SIGN guidelines (see paragraph 13.93, above) for therapy adopt an evidence-based hierarchy, with treatment based upon HCV genotype.<sup>152</sup>

**13.98** For Genotype 1 patients, all 'treatment naïve' patients (those who have not previously undergone antiviral treatment) with Genotype 1 should be considered for treatment with pegylated Interferon and weight-based Ribavirin, with the addition of a protease inhibitor as triple therapy. The same treatment should be considered for those who have failed previous antiviral treatment.

**13.99** For Genotype 2 and 3 patients, standard treatment is pegylated interferon and weight-based Ribavirin for 24 weeks. Non-cirrhotic patients with Genotype 2 or 3 who achieve a 'rapid viral response', in which HCV RNA is undetectable, indicating the efficacy of therapy at week four, should be considered for a shortened duration of therapy of 12–16 weeks.

**13.100** For patients with Genotypes 4, 5 and 6, standard treatment is 48 weeks of pegylated interferon and weight-based ribavirin.

**13.101** In general, a sustained viral response can now be achieved following treatment based upon the above regimes in almost 80% of patients able to tolerate and complete the prescribed courses of treatment. Full details can be found in SIGN 133: Management of Hepatitis C (2013) along with references to the relevant research literature and analysis.<sup>153</sup>

**13.102** HCV particles have a relatively short half life in circulation (that is, the virus particles decay quite rapidly in the bloodstream). In contrast, infected liver cells have a relatively long half life (decay is considerably longer). In patients whose treatment is likely to be successful, the initial rate of disappearance of HCV RNA during interferon therapy is rapid and viraemia does not return. This is reflected in the shortened period of therapy noted at paragraph 13.99 above. In patients whose treatment is likely not to be successful, initial clearance is followed by a second phase of less rapid clearance which may reflect the presence of an interferon-resistant second site of HCV infection within or outside of the liver.<sup>154</sup> If HCV RNA is still positive at the twelfth week of therapy, treatment is usually stopped because the chance of a sustained viral response is insignificant.<sup>155</sup>

<sup>153</sup> SIGN 133: *Management of Hepatitis C* (2013) [LIT.001.5550] at 5577–82

<sup>154</sup> Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1082–83

<sup>155</sup> Professor Thomas – Day 53, page 51

**13.103** In the case of patients treated after they already have cirrhosis, Hepatitis C is unlikely to be cured (partly because they have been infected for so long and partly because they find it harder to tolerate treatment).<sup>156</sup> Cirrhosis does not disappear even when a positive response is achieved and the condition puts the patient at continuing risk of liver cell cancer. In this group clinicians should not be talking about a 'cure' of a patient's overall condition because they are still at risk of this severe complication. However, in these patients the risk of progression to hepatic decompensation and possible HCC is reduced and they are no longer infectious: they have a 'viral cure'.<sup>157</sup>

**13.104** The use of the term 'cure' was the subject of questioning during the oral hearing. The expression that had been commonly used was 'sustained viral response' (SVR), meaning undetectable HCV RNA six months after the end of treatment. Professor Thomas thought that it was now appropriate to speak of treatment 'curing' the patient, provided that treatment was given before the patient had developed cirrhosis.<sup>158</sup> He explained that until there had been many years of long-term follow-up showing that viral relapse was a very infrequent occurrence, clinicians were conservative about translating 'SVR' into the word 'cure'. It was not simply a matter of virological 'cure': one wished to know that, if there was sustained viral response, then fibrosis regressed and scarring was re-absorbed.<sup>159</sup> Generally, if HCV RNA were to reappear, it would be within the first few months after the end of treatment. For those who have SVR before the onset of cirrhosis, the liver should ultimately go back to normal. Professor Thomas emphasised the word 'should': there had been only a few years of observation and it might take longer than that period to progress to normal in terms of scarring of the liver; it is an evolving field of investigation. In relation to haemophilia patients it had not been possible to do frequent biopsies. However, non-invasive techniques, using fibro-elastography technology, are now available to subject the liver to an ultrasound wave and measure how much the organ wobbles. The stiffness of the liver is related to the scarring in it and that stiffness should reduce in somebody with an SVR. The evidence now available shows that it does indeed reduce. It may be several years before the liver actually goes back to normal and to date there has not been a large enough cohort of patients to enable clinicians to state definitively that the liver will go back to normal. However, 'cure' is now held to be an appropriate description in non-cirrhotic cases.<sup>160</sup>

**13.105** This is an important development for people who, perhaps encouraged by stories spread around patient groups, may have resisted treatment on the grounds that Hepatitis C was not curable and that treatment might not be effective and would have serious side-effects.<sup>161</sup> Professor Hayes commented that there are still some patients who seem to have fairly benign disease and who are happy to have no treatment, despite the fact that treatment is improving.<sup>162</sup> People who do not have Genotype 1 are strongly encouraged to go for treatment.<sup>163</sup> About 20% of individuals do not manage to complete treatment, principally due to side-effects.<sup>164</sup>

<sup>156</sup> Professor Hayes – Day 78, page 87

<sup>157</sup> Professor Thomas – Day 53, page 58

<sup>158</sup> Ibid pages 56–58

<sup>159</sup> See also Professor Hayes – Day 78, pages 52–53

<sup>160</sup> Recent analysis carried out for SIGN 133 suggests that occult Hepatitis C may persist in macrophages or lymphocytes in a small number of patients who have achieved SVR. There may be a small chance of relapse in this event.

<sup>163</sup> Ibid page 96

<sup>164</sup> Ibid page 97

### *Side-effects of treatment*

**13.106** Interferon alone produced flu-like symptoms and, taken three times a week, it made patients feel awful.<sup>165</sup> Pegylated Interferon is taken once a week with proportionately better impact, although some people still find it debilitating. The side-effects that most concern clinicians are depression and occasional suicidal ideation (thoughts about or preoccupation with suicide). Ribavirin is also associated with side-effects, particularly anaemia. Professor Hayes said that the patients would best understand the side-effects themselves: individual tolerance varied widely but each addition to the cocktail of drugs expanded the range of side-effects. Managing side-effects by reducing doses impacted on success rates. With Ribavirin, it has proved more effective to maintain the standard (weight-based) dose and support haemoglobin by the use of drugs such as erythropoietin. New drugs, while likely to improve the chance of a cure, are likely to have the same side-effects 'plus extra'.<sup>166</sup>

**13.107** The common side-effects from pegylated Interferon and Ribavirin are summarised in paragraph 2.44 of the Preliminary Report. A more comprehensive list is set out in the SIGN (Scottish Intercollegiate Guidelines Network) guidelines.<sup>167</sup> In summary these are:

- Flu-like symptoms, such as fever, myalgia (muscle pain), rigors ('chills'), arthralgia (joint pain) and headache. These symptoms are similar to those experienced in acute hepatitis when the body produces interferon. In therapeutic use, interferon is administered in larger amounts than a body would otherwise produce, with the result that the same symptoms are caused and magnified.<sup>168</sup> These symptoms are usually treated with paracetamol, increased fluid intake and rest. Patients are advised to coordinate their injections of interferon with periods of reduced activity, such as weekends and holidays.
- Anaemia (decrease in number of red blood cells or less than the normal quantity of haemoglobin in the blood) and neutropenia (an abnormally low number of neutrophils, a type of white blood cell). Anaemia is primarily related to ribavirin. Initially this was treated by reducing the patient's dose of ribavirin which affected the success rate of the treatment.<sup>169</sup> More recently Erythropoietin is prescribed which enables a patient to continue taking the prescribed dose of ribavirin.<sup>170</sup> Likewise, Granulocyte colony stimulating factor may now be prescribed for patients who develop significant neutropenia instead of reducing ribavirin.
- Depression is a commonly reported and serious side-effect of pegylated interferon and ribavirin treatment in patients, whether they have experienced depression before or not. Occasionally patients experience suicidal ideation. All patients receiving this treatment should be monitored for symptoms of depression before, during and immediately after treatment. Those who experience depression should be considered for treatment with antidepressants and referred to a specialist.
- Severe skin reactions are uncommon during treatment but dry skin, pruritus (itch) and diffuse eczematous lesions occur in approximately 20% of patients. Psoriasis may be exacerbated by the treatment. Injection site reactions occur in over 50% of treated patients. Such conditions may be treated by emollients and topical corticosteroids.

<sup>165</sup> It is the body's natural production of interferon that makes a person with flu feel 'fluey'.

<sup>166</sup> Professor Hayes – Day 78, pages 100–104

- Up to 6% of those treated may develop thyroid dysfunction, both over- and under-active thyroid, as a result of interferon therapy. Females are more at risk of this complication. This side-effect is not always reversible and a patient may require long-term treatment as a result.
- Weight loss is commonly reported in patients on antiviral treatment. Nutritional support may be required.
- Shortness of breath is a rarely reported side-effect of treatment. It may be linked to development of anaemia or may be caused by more serious cardiovascular or respiratory conditions.
- Retinopathy (damage to the retina) during interferon treatment is common but it is usually mild and transient. It resolves spontaneously when the treatment stops and treatment is seldom required.
- Alopecia is a relatively common reported side-effect of treatment. Hair usually grows again when the treatment stops.
- Fatigue is one of the most commonly reported side-effects of treatment, with anaemia, under-active thyroid, sleep disturbance and depression all contributing.
- Other reported side-effects include insomnia, poor concentration, oral disease, nausea and post-treatment withdrawal symptoms.

### *Timing of treatment and further procedures*

**13.108** Clinicians' views about when to treat a patient have evolved over the years within the reference period.<sup>171</sup> Prior to 2004, NICE<sup>172</sup> recommended that only those patients with severe disease should be treated and that the assessment of the severity of the disease should be based on a liver biopsy.<sup>173</sup> Due to the additional risks of a liver biopsy for those patients with haemophilia, they were excluded from this requirement.<sup>174</sup> In April 2004 at a Consensus Conference on Hepatitis C in Edinburgh it was decided that a liver biopsy was no longer essential to determine selection of patients for therapy. Then in 2005 the Scottish Executive produced the 'Hepatitis C Action Plan for Scotland'.<sup>175</sup> This highlighted the importance of treating as many people as possible rather than tailoring treatment to those persons clinicians believed needed it most.<sup>176</sup>

**13.109** Issues are raised as to how soon after the known date of infection, treatment should be instituted. Treatment within three months of infection as opposed to treatment within months four to six makes no significant difference and most people clear infection within three months anyway, if they are going to do so spontaneously. In the case of surgeons who may contract or transmit infection from or to patients, tests are carried out every two weeks. If viraemia occurs, treatment is instituted within the period three to six months.<sup>177</sup> This is highly successful.

<sup>171</sup> Professor Hayes' report on Hepatitis C [PEN.018.0240] at 0245

<sup>172</sup> NICE, the National Institute for Clinical Excellence (National Institute for Health and Clinical Excellence since 2005) publishes guidelines for use in the NHS in England and Wales on the use of health technologies and clinical practice.

<sup>173</sup> Professor Hayes – Day 78, page 81; Professor Hayes' Report on Hepatitis C [PEN.018.0240] at 0244. The severity of the disease is assessed by the pathologist who, having had regard to the amount of inflammation and scar tissue, grades the liver biopsy samples as mild, moderate and severe.

<sup>174</sup> Professor Hayes – Day 78, page 82

<sup>175</sup> *Hepatitis C Action Plan for Scotland* [LIT.001.4948]

<sup>176</sup> Professor Hayes – Day 78, pages 84–85

<sup>177</sup> Professor Thomas – Day 53, pages 82–84

**13.110** A person with cirrhosis may be less able to tolerate the treatment complications as well as the problems caused by cirrhosis.<sup>178</sup> It is far better to prevent a person developing cirrhosis than to deal with the consequences of it, although for a clinician it is difficult to identify when adverse developments may occur.

### Hepatocellular cancer

**13.111** The management of hepatocellular cancer (HCC) is complex. Recent literature on the subject has set out a number of options.<sup>179</sup> If possible, transplantation is the preferred treatment in generally 'well-compensated' patients (patients with good clinical and biochemical profiles) who have either one tumour less than five centimetres in size or up to three tumours each less than three centimetres in size. In these cases, there must be no extra-hepatic spread, and the tumour or tumours must not involve any blood vessels. However, the proportion of patients with hepatocellular cancer who are suitable for a liver transplant is very small.<sup>180</sup> Professor Hayes said:

[L]iver transplant is ... certainly indicated in some patients. It has the advantage that it gets rid of the cirrhotic liver. Once you have started to form one tumour in the liver, we believe that you are likely to form more. There is what we call a field change, and it is not uncommon that if you find a tumour you actually find two or three.<sup>181</sup>

**13.112** Liver transplantation is a complex, expensive and risky treatment. Transplant of the liver of a donor without haemophilia cures the haemophilia patient recipient of that condition: the implant synthesises Factor VIII normally.<sup>182</sup> Liver transplantation does not totally remove HCV from the recipient, however, as the virus infects parts of the body other than the liver. Immunosuppressant medication, given to prevent rejection of the transplanted liver, weakens the body's overall ability to deal with the virus. Hepatitis C will therefore always infect the new liver and the natural history from infection to cirrhosis is often considerably accelerated in the transplanted liver – a newly transplanted liver may become cirrhotic within two years of transplantation.<sup>183</sup> One of the reasons for this is that a patient is immunocompromised post-transplant and his ability to clear the virus is therefore impaired.<sup>184</sup> Recent SIGN advice is, therefore, that patients should be considered for antiviral therapy after liver transplant to achieve HCV clearance in cases of recurrent HCV-related liver disease.<sup>185</sup>

**13.113** In a very small proportion of clinically well patients with optimal liver function test scores who have small single nodules, surgical resection (to remove the segment of the liver containing the tumour) may be carried out. Professor Hayes noted that targeted treatment risks leaving a liver that is prone to developing new tumours.<sup>186</sup>

**13.114** In other patients who are not suitable for surgery, percutaneous radio frequency ablation may be used. This is a procedure whereby, under imaging control, heat generated from a high frequency alternating current is inserted directly into the tumour in order to

kill it. Injection with ethanol is indicated for multiple tumours up to three centimetres in size. For tumours up to about five centimetres, trans-arterial chemoembolisation is used if patients do not have widespread disease, vascular involvement, or marked hepatic decompensation. In this procedure the blood vessels supplying the tumour are selectively blocked off following the introduction of the anticancer drugs directly into a tumour via its blood supply. Beyond this, chemotherapy or palliative care is used for cases which are unsuitable for liver transplantation.<sup>187</sup> Chemotherapy treatments are seldom very effective.

### Drug therapy

**13.115** Several drugs in the class of protease inhibitors (Telaprovir and Boceprevir) have recently been licensed for use alongside pegylated Interferon and Ribavirin and, according to trial data, will increase response rates in Genotype 1 patients to 70–80%. Telaprovir was approved for prescription in December 2011.<sup>188</sup> In addition, variations in the IL28 (lambda) gene appear to influence the chance of response (see paragraph 13.67 above) and this genetic predictive test is now finding a place in the selection of patients for treatment.<sup>189</sup> Health economics will affect availability. The side-effects of using protease inhibitors are expected to be more severe. Professor Thomas discussed both aspects:

I think the side effects will be more severe with the protease inhibitors because when similar ... but not identical compounds, are used in HIV, then they have caused liver toxicity... [A]ccumulation of fat in the liver, for instance, has been seen with some of the HIV-active protease inhibitors. So how that will work through with Hepatitis C is not 100 per cent clear.

Telaprevir has been causing quite severe rashes. But the final costing is going to be dependent on ... [the] predictive polymorphism of IL28, which is a lambda interferon ... strongly associated with response to treatment. So it might allow you to pick out those people who are going to respond to pegylated interferon and ribavirin from those who won't, and that latter group might then, instead of going through a trial of the pegylated interferon and ribavirin, they might start initially into those two drugs with the protease inhibitor.

And that will influence the health economics. And then there will be the issue of early-stopping rules of the type... [applied to] interferon and ribavirin because if you can, at an early stage, identify those that are going to be successfully cured, then again that will increase the cost-effectiveness. So there are several groups now looking at, in preparation for NICE, what the management algorithm might look like, and I presume that ultimately that may influence what the costs would be.

....

And the unknown, of course, is the competitive issue as well... telaprovir is made by Vertex and boceprevir is made by Schering-Plough, but they have just been bought by Merck Sharp and Dohme.

....

<sup>187</sup> Ibid pages 89 – 92

<sup>188</sup> Ibid page 130

<sup>189</sup> Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1083

One of the figures that was cited was that it might cost up to £18,000 for a combined course of pegylated interferon, ribavirin and one of these protease inhibitors. And ... I think ... a full year's course of interferon and ribavirin probably costs about £10,000, that sort of level. So they are looking at doubling it in anticipation of the doubling the response rate, so that the cost per cure is slightly improved on what it is now. So when you do the cost-effectiveness analysis, it will come out as a significant improvement.<sup>190</sup>

**13.116** Professor Hayes said that trial data relating to these two new recently-licensed drug treatments suggests that they could herald a 'quantum improvement' in responses, at least for Genotype 1 patients. He also suggested that new treatments, with the added benefit of being taken in oral form over a short course (rather than by frequent injection), might be on the horizon which could be 'remarkably effective'.<sup>191</sup> Professor Thomas said that there was no condition with more drugs in the pipeline than Hepatitis C: by 2015 there will be about 30 waiting in the wings.<sup>192</sup>

**13.117** It is not known at present what the implications are for patients requiring treatment for different genotypes from each of the two relevant treatment groups (haemophilia or post-transfusion patients). Professor Thomas said there was only a relatively small number of relevant patients for whom this is an issue. In the case of haemophilia patients he said:

I think the other thing that has been a problem in treating the haemophilia population is that the interferons have been given subcutaneously and of course, we are worried about forming haematomas by having to inject three times a week. The pegylated interferons ... we only inject now weekly. So that problem is starting to diminish. And initially, when we had to give the injections more frequently, we gave them intravenously to make sure we didn't cause haematomas.

When we were only looking at 12 to 15 per cent response rates, when you are explaining the risk/benefit to the patient, the need for repeated intravenous injections was something that would be considered -- in genotype 1 it would have to continue for a year. That would be discouraging to the patient, I would think.<sup>193</sup>

### Co-infection with HIV

**13.118** Co-infection with HIV complicates the picture.<sup>194</sup> Professor Thomas explained that the issue has always been whether to give highly active retroviral therapy first and then Hepatitis C treatment, or to do it the other way round. In the main, patients are treated for HIV first and then interferon and ribavirin treatment would be added in. The progression of Hepatitis C in the main is much slower than untreated HIV. If the problems can be decoupled by treating HIV first, the situation is improved: a sustained viral response with standard pegylated interferon and ribavirin after treatment of HIV is more likely. Professor Thomas thought that the overall data suggested that the sustained viral response rates in co-infected patients are probably about half what one would otherwise see, so that,

<sup>190</sup> Professor Thomas – Day 53, pages 52–54

<sup>191</sup> Professor Hayes – Day 78, pages 105–106

<sup>192</sup> Professor Thomas – Day 53, page 55

<sup>193</sup> Ibid page 64

<sup>194</sup> Ibid pages 79–82

in the case of a Genotype 1 patient, there might be a response rate of around 20–25%, instead of 40%. How much of that would be corrected by prior treatment of the HIV he did not think was known at the moment but logically one would expect it to be improved. In terms of delay, prior treatment of HIV infection would be insignificant in relation to the progression of Hepatitis C.

### **Morbidity and mortality associated with HCV**

**13.119** The discussion so far has sought to describe the clinical features, natural history and treatment of chronic Hepatitis C, together with co-morbidities and factors which may accelerate the course of the disease. The two 'populations' affected by Hepatitis C who form the subjects for the Inquiry comprise (i) haemophilia patients, almost all male, the majority of whom were infected in the first 30 years of their lives and many of whom were co-infected with HIV; and (ii) those infected as a result of blood transfusion, the majority of whom were over age 40 at the time of infection. Many of the latter group died in the first two to five years after infection as a result of causes quite unconnected with HCV (very often connected, instead, to the primary condition that required medical intervention including blood transfusion). There have been numerous studies of cohorts of patients in each population that have contributed to understanding of the morbidity and mortality associated with HCV and HCV/HIV infection.

#### *HCV associated with haemophilia treatment*

**13.120** The clinical and treatment records of 310 haemophilia patients registered at the Royal Free Hospital Haemophilia Centre were analysed by Dr Thynn Thynn Yee and others.<sup>195</sup> The study provided concrete evidence for the generally held view that almost all haemophilia patients treated with Factor VIII concentrates prior to 1985 (when virucidal treatment of concentrates was introduced) were infected with HCV, at least after the introduction of large-pool clotting factors.<sup>196</sup>

**13.121** The study concluded that the 25-year follow-up of the whole group showed the potentially lethal combination of HIV and HCV co-infection. Individuals infected with HCV alone showed slow progression of liver disease. In terms of prognosis, the article stated:

HCV infection is now recognised as a major risk factor for HCC and there seems to be an incubation period of two or three decades on average ... HCC... is likely to become more common in this group of patients who were infected from 1977 (median year).<sup>197</sup>

**13.122** A major follow-up study among haemophilia patients from Sheffield, Utrecht and including the Royal Free cohort related to 847 patients with HCV antibodies extending for up to 42 years (median 27 years). Of these, 687 (81%) developed chronic Hepatitis C and 210 were co-infected with HIV. There were 199 deaths, 73 of which were attributable to AIDS, and 55 were 'liver related' of whom 31 had HIV/HCV co-infection. Twenty-four HIV-negative patients (4%) had died of liver disease. Seventy-one of the total cohort developed End-stage Liver Disease (ESLD). Thirteen had had a liver transplant. The

<sup>195</sup> Yee et al, 'The Natural History of HCV in a cohort of haemophilic patients infected between 1961 and 1985', *Gut*, 2000; 47: 845–851 [LIT.001.4318]

<sup>196</sup> Factor IX in 1961 and Factor VIII in 1976 in this population.

<sup>197</sup> Yee et al, 'The Natural History of HCV in a cohort of haemophilic patients infected between 1961 and 1985', *Gut*, 2000; 47: 845–851 [LIT.001.4318] at 4323

cumulative incidence of ESLD after 35 years was 11.5% in HIV-negative individuals. The risk of developing ESLD was also associated with age at HCV infection (older patients at date of infection being more at risk) and with history of alcohol abuse.<sup>198</sup>

**13.123** In Canada, the federal, provincial and territorial governments agreed to pay compensation to individuals who became infected with HCV through blood and blood product transfusions between 1 January 1986 and 1 January 1990 on the ground that surrogate marker testing for infection, which had been in place in the USA, had not been implemented in most Canadian jurisdictions. Between 10,000 and 16,000 Canadians were thought to have been infected in that period. Patients with post-transfusion chronic HCV infection, haemophilia patients, patients co-infected with HIV and patients with secondary infections (for example, the sexual partners of those with haemophilia and HCV) were covered by the compensation scheme. Compensation, for viraemic patients, was related to a scale of mutually exclusive stages:

Liver fibrosis stage:

- F0, no fibrosis, to F4, cirrhosis

Clinical status stages:

- Decompensated cirrhosis
- Hepatocellular Carcinoma (HCC)
- Death

**13.124** Accurate prognostic data were required to ensure the sufficiency of the compensation fund and that entailed assessment of the clinical characteristics of the claimant cohort to determine annual fibrosis stage-specific transition probabilities. HCV treatment efficacy was factored into the exercise. Dr Hla-Hla Thein and others reported their findings using base-line clinical data on 5004 patients from 2007.<sup>199</sup> By then, 1231 patients had died (including 401 haemophilia patients) and 3773 were alive (including 904 haemophilia patients). Biopsy evidence was available in 1082 cases (including 225 haemophilia patients).

**13.125** It was assumed that 20% of individuals who acquired HCV infection would clear the infection within six months, with an annual clearance rate thereafter of 2%.<sup>200</sup> The model did not assume a constant rate of progression of liver fibrosis; rather, it assumed use of up-to-date treatment with pegylated Interferon and Ribavirin for all in need. The researchers found that, 20 years after the index transfusion, 10% of all living claimants had cirrhosis and 0.5% had developed HCC. Predicting forward a further 20 years, the risks were computed, giving the following results for haemophilia patients (HCV and HCV/HIV co-infected patients combined):

- Risk of HCV-related cirrhosis      37%
- Risk of HCC                              12%
- Risk of liver-related death          19%

<sup>198</sup> Posthouwer et al, 'Progression to end stage liver disease in patients with inherited bleeding disorders and hepatitis C: an international, multicentre cohort study', *Blood*, 2007; 109: 3667-3671 [LIT.001.4090]

<sup>199</sup> Thein et al, 'Prognosis of hepatitis C virus-infected Canadian post-transfusion compensation claimant cohort', *Journal of Viral Hepatitis*, 2009; 16: 802-813 [LIT.001.4184]

<sup>200</sup> Professor Thomas – Day 52, pages 56-57. The lower end of the range proposed by Professor Thomas was 30%: see Professor Thomas' report on Hepatitis C [PEN.017.1071] at 1074

**13.126** It was noted that haemophilia patients were usually younger than patients infected post-transfusion and were often co-infected with HIV. For the haemophilia group, the cumulative lifetime risk of cirrhosis was estimated at 45%, and of liver-related death 30%. These figures did not include HCV/HIV co-infected patients.

### *Post-transfusion chronic Hepatitis C*

**13.127** Examination of long-term morbidity and mortality from post-transfusion HCV is bedevilled by a number of difficulties. Invariably, a very significant proportion of those infected following transfusion die before the study is completed, often of the morbidity which led to the original need for transfusion. A Scandinavian follow-up over 20 years of over a million transfusion recipients showed standardised mortality rates after one, five and 20 years of 17.6, 2.1 and 1.3 times the general public, respectively.<sup>201</sup> Of these, 65% were dead after 10 years and 77% were dead after 20 years. Furthermore, in look-back studies low proportions of potential subjects come to light and are available for study: there is an unavoidable risk of selection bias and this is reflected in the results brought out.

**13.128** In the UK, Dr Helen Harris and colleagues reported on a study of the natural history of HCV after 16 years of infection carried out on behalf of the HCV National Register Steering Group. The patients all had acquired infection from blood transfusion in the UK on an identified date. All had been traced through the national HCV look-back study. They estimated that at median seven years post-transfusion 61% of the patients identified in the look-back had died.<sup>202</sup> Almost none of these patients would have died of HCV-related causes after this short post-transfusion period.

**13.129** In Denmark, HCV antibody screening was introduced in 1991. Thereafter, 150 HCV-positive donors were identified.<sup>203</sup> A look-back study of post-transfusion chronic HCV in 1996 identified 1018 recipients of blood from those donors. By then 230 were alive, 22.6%, and 77.4% had already died. The Danish health information systems allowed much fuller and more complete ascertainment of subjects than in the UK. Results of a median follow-up of 18 years (21.8 years in survivors) were published in 2011. The authors found that by 2009 only 121 of 1018 known recipients (11.8%) were still alive.

**13.130** In the circumstances, individual studies of morbidity and mortality among surviving patients have to be treated with a degree of caution: the surviving cohort are not necessarily representative of the total population, including those who have died before the date of study. Additionally, data expressed in percentage terms may be misleading. General impressions can nevertheless be gained from a survey of a range of sources. There may be few subjects alive in any sub-group. In the Danish study by Dr Søren Just and colleagues, it was found that there was no difference in all-cause mortality among the 230 HCV-exposed recipients alive in 1996 and followed to 2009 when compared with unexposed controls (a matched group of transfusion recipients not exposed to HCV-infected blood). The authors also found that rates of liver-related disease were not significantly different between the infected and uninfected recipients of HCV-infected blood when adjusted for age, co-morbidity and other factors. Liver-related mortality overall was increased significantly. Relative risk of liver-related death in the HCV-infected group was increased tenfold, although this represented only nine deaths.

<sup>201</sup> Kamper-Jorgensen et al, 'Survival after blood transfusion', *Transfusion*, 2008; 48 [LIT.001.4069]

<sup>202</sup> Harris et al, 'Survival of a national cohort of hepatitis C virus infected patients, 16 years after exposure', *Epidemiology and Infection*, 2006; 134: 472–477 [LIT.001.3898]

<sup>203</sup> Just et al, 'Long-term follow up among Danish transfusion recipients identified in the national hepatitis C lookback', *Transfusion*, 2001 [PEN.018.0507]

**13.131** The study by Harris and colleagues found that, after 16 years of infection, transfusion recipients who tested positive or indeterminate for antibodies to HCV were at increased risk of dying from liver disease compared to anti-HCV negative transfusion recipients. They found that, at median 16 years post-transfusion, the relative risk of all-cause mortality compared with transfused but HCV-negative controls was 1.17 (NS);<sup>204</sup> and that relative risk of death directly from liver disease was 2.71 ( $p = 0.03$ ).<sup>205</sup> There was also a significant – indeed larger – difference in survival to death certified as *liver-related* at 5.04 ( $p=0.003$ ).

**13.132** A very long-term US follow-up (25 years) by Dr Leonard Seeff and colleagues of the original NANB Hepatitis cohort studies in the USA showed overall mortality of 67% in the HCV-positive cohort versus 65% in HCV-negative controls.<sup>206</sup> As with the UK and Danish studies, liver-related deaths, at 4.1% in HCV-positive patients versus 1.3% in controls, were significantly increased ( $p=0.05$ ), but represented only a small fraction of overall deaths. The authors stated that:

For the entire cohort of patients initially infected with HCV, the estimate for progression to cirrhosis is 17%. Thus, over an approximate 25-year interval, HCV infection did not lead to increased [overall] mortality and resulted in severe histological lesions in fewer than 20%.

Whether those with histologically defined chronic hepatitis alone will progress to cirrhosis, and whether mortality and morbidity will continue to derive mainly from those with established cirrhosis, remains to be determined.<sup>207</sup>

**13.133** In the Canadian study by Thein and colleagues, for post-transfusion HCV patients, among 3699 individuals of whom 857 had liver biopsy evidence, modelling showed:

- Risk of HCV-related cirrhosis                      23%
- Risk of HCC    7%
- Risk of liver-related death                              11%

**13.134** Dr Gary Davis and colleagues have recently reported the results of a multi-cohort natural history modelling study of disease progression in what has become an ageing population of US patients.<sup>208</sup> This study, which is most sophisticated and well-informed, used multiple disease cohorts to study cirrhosis, hepatic decompensation, HCC and death. Projections were developed, differentiated for sex, age at infection and duration of infection up to 30 years. Rates of liver-related morbidity and mortality at 30 years were derived as follows:

<sup>204</sup> 'NS' denotes that there is no significant difference, particularly when the difference between two categories is smaller than the amount of error that is expected to be in the data as 'noise'.

<sup>205</sup> A p-value expresses the probability that a given hypothesis is false. The lower the p-value, the more likely it is that the hypothesis is valid. In this case, the p-value indicates that the authors had estimated that, notwithstanding the calculated risk of 2.71 on available data, there was a 3% chance that the calculation was wrong.

<sup>206</sup> Seefe et al, 'Long-term mortality and morbidity of transfusion-associated non-A, non-B, and type C hepatitis: a National Heart, Lung, and Blood Institute collaborative study' *Hepatology*, 2001; 33: 455–463 [LIT.001.3951]

<sup>207</sup> Ibid [LIT.001.3951] at 3958

<sup>208</sup> Davis et al, 'Aging of hepatitis C virus (HCV)-infected persons in the United States: a multiple cohort model of HCV prevalence and disease progression', *Gastroenterology*, 2010; 138: 513–521 [LIT.001.4046]

**Table 13.1: Projections by cohort of all infected patients**

	Percentage after 30 years			
	Cirrhosis	Decompensated cirrhosis	HCC	Liver death
Females: Age 0–30 at infection	4.24	0.44	0.02	0.92
Females: Age 31–50 at infection	7.75	0.79	0.04	1.28
Females: Age over 50 at infection	7.36	0.80	0.12	2.29
Males: Age 0–30 at infection	13.92	1.55	0.19	2.91
Males: Age 31–50 at infection	38.11	5.13	0.50	11.14
Males: Age over 50 at infection	15.24	2.21	0.56	15.06

**13.135** The authors cite a number of other studies showing that, after long-term follow-up, all-cause mortality and non-liver mortality may also be increased in older individuals with chronic HCV infection.

**13.136** One such study, by Dr Anne Guiltinan and colleagues, dealt with a large number of blood donors for whom records were available at 17 blood centres in western and southern USA.<sup>209</sup> They identified 10,259 confirmed HCV-positive donors who had donated blood between 1991 and 2002, and 10,259 HCV antibody-negative donors matched for year of donation, age, gender and ZIP (postal) code. After a mean follow-up of 7.7 years, they found excess mortality in the HCV infected group as follows:

**Table 13.2: Excess mortality in HCV positive donors compared to HCV-negative donor controls<sup>210</sup>**

	HCV positive	HCV negative	Total	Hazard ratio <sup>211</sup>
Liver-related deaths	90	2	92	45.99
Drug/alcohol-related deaths	64	6	70	10.81
Cancer excluding liver	56	53	109	1.09
Trauma/suicide	106	36	142	2.99
Cardiovascular	60	28	88	2.21
Pulmonary	8	7	15	1.18
Stroke	13	6	19	2.20
Infection	23	2	25	11.73
Other/unknown	33	8	41	4.23
Total deaths	453	148	601	3.13

<sup>209</sup> Guiltinan et al, 'Increased all cause, liver, and cardiac mortality among hepatitis C virus-seropositive blood donors', *American Journal of Epidemiology*, 2008; 167: 743–750 [LIT.001.4061]

<sup>210</sup> 'Excess' meaning high relative to the general population.

<sup>211</sup> Hazard ratio: the risk of death expressed as a ratio of [deaths in HCV+ve donors]/[deaths in HCV-ve donors].

**13.137** The authors commented that the estimated annual risk of death due to liver disease was 1:1000 or, cumulatively, about 2% over 20 years of life following infection. Liver cancer accounted for about one fifth of these deaths, about 0.4% cumulative risk over the same period. Multivariate analysis did not change significantly the association between HCV infection and all-cause mortality.

**13.138** The donors were presumed to be unaware of their infection and to have been in apparently good health at the time of donation, having passed blood donor medical selection criteria. Under-reporting of HCV risk factors was likely, however.

**13.139** These studies, in unselected post-transfusion patients with acquired chronic HCV infection and in other populations of those infected with HCV, indicate consistently that after 18–25 years or more post-infection:

- (i) A relatively small proportion of post-transfusion infected patients remain alive, many having died within a few years of transfusion of causes not related to HCV.
- (ii) While mortality directly attributable to liver disease is increased in these patients compared to HCV-negative transfused controls, this has so far amounted to less than five per cent of total deaths among those surviving 10 or more years after transfusion.
- (iii) Of the survivors alive more than 25 years post-infection, a significant proportion (up to 25%) may ultimately go on to develop cirrhosis and become exposed to risk of its complications, namely liver failure and HCC.

**13.140** There is a possibility that, for reasons as yet unknown, those relatively few survivors of post-transfusion HCV, or the haemophilia patients with HCV in the UK who survive for more than 30 years after acquiring HCV infection, may have a slightly increased all-cause mortality and non-liver-related mortality. It seems more likely, however, that such findings in HCV-positive patients as a whole are due to factors associated with their previous lifestyles rather than to some as yet unidentified non-hepatic factor associated with long-term HCV.

**13.141** Many studies have demonstrated that older age at acquisition of HCV infection is associated with more rapid progression of liver disease. However the Inquiry has found no evidence that, in individuals who acquired HCV at younger ages, there is an age-dependent acceleration in the rate of progression of liver disease, independent of other variables (such as alcohol, obesity or smoking, discussed above).

**13.142** Finally, can these studies be improved upon? One of the doyens of the study of Hepatitis C, Dr Leonard Seeff (principal author of the study at paragraph 13.132 above), has recently written:

Some [of those infected with HCV] will even progress through life without ever knowing that they are HCV infected, while others may suffer from varying degrees of fatigue and a decreased quality of life. In order to accurately establish the frequency of these variable outcomes, it would be necessary to mount a life long study of a large cohort from the time of infection and follow them until their demise.... [I]t would be almost impossible to pursue a study of this duration...<sup>212</sup>

<sup>212</sup> Seeff, 'The History of the 'natural history' of hepatitis C (1968 – 2009)', *Liver International*, 2009; 29:, 89–99:[LIT.001.4100] at 4106

**13.143** It now seems unlikely that any further studies will provide much more definitive information in future. Because of the advent of effective treatment, the era of natural history studies of chronic Hepatitis C has probably passed.

#### *Impact of co-infection with HIV*

**13.144** As already noted, in patients co-infected with HIV the rate of HCV replication is higher, and the level of viraemia is also relatively high. In the UK many haemophilia patients became co-infected with HIV and HCV. Very few post-transfusion HCV patients, if any, had this problem. Overall, parenteral drug use has caused the majority of cases of HIV/HCV co-infection and studies of this cohort best inform current understanding of the problem.

**13.145** The Royal Free Hospital, Sheffield and Utrecht study of 847 haemophilia patients exposed to HCV infection, of whom 210 were co-infected with HIV, showed that the cumulative incidence of ESLD among co-infected individuals was 35.1% at 35 years as against 11.5% in HIV-negative subjects. Deaths from liver disease were 21 of 210, plus 73 deaths from AIDS in the co-infected patients.<sup>213</sup>

**13.146** Meta-analysis of 17 studies, reported in 2008, indicated more rapid progression to cirrhosis in patients co-infected with HIV than in patients infected with HCV alone.<sup>214</sup> Drawing on previous reports, 3567 patients were studied. The study also analysed data distinguishing results for patients treated with highly active anti-retroviral therapy (HAART). Over the period studied, HAART did not appear to correct fully the adverse effect on HCV prognosis of co-infection with HIV.

**13.147** The estimated mean transition probabilities between fibrosis stages were calculated. There was a significant association between the duration of HCV infection and the rate of progression of fibrosis: with longer duration the rate of progression slowed. By contrast, among co-infected individuals, it was concluded that the rate of fibrosis progression appeared to be constant.

**13.148** Prevalence of cirrhosis in co-infected individuals was 21% after 20 years and 49% after 30 years. The overall ratio of cirrhosis in co-infected individuals relative to cirrhosis in patients infected with HCV alone was 2:1. It was concluded that chronic Hepatitis C outcomes were worse for co-infected individuals.

#### **Conclusion**

**13.149** As indicated in paragraph 13.2, the narrative of patients' experiences of infection with NANB Hepatitis virus/HCV is best understood in light of the most up-to-date knowledge of the disease. In that way, patients' reports of signs and symptoms associated with infection can now be explained even when they would not have been understood at the time of report to be related to NANB Hepatitis virus/HCV infection. Current knowledge provides the appropriate background for an informed appreciation of the accounts patients and their relatives have given of their experiences of HCV infection, whatever the date or dates of those experiences. However, it has to be repeated that very little of the information relating to the natural history of HCV infection which is

<sup>213</sup> Posthouwer et al, 'Progression to end stage liver disease in patients with inherited bleeding disorders and hepatitis C: an international, multicenter cohort study', *Blood*, 2007; 109: 3667–3671 [LIT.001.4090]

<sup>214</sup> Thein et al, 'Natural history of hepatitis C virus infection in HIV-infected individuals and the impact of HIV in the era of highly active retroviral therapy: a meta-analysis', *AIDS*, 2008; 22: 1979–1991 [LIT.001.4077]

available now, in 2014, would or could have been known until well into the 1990s, after the patients with whom this Report is concerned were already infected by transfusion of blood, blood components or blood products. Hindsight cannot support a view of what should have been understood at earlier periods.

**13.150** The element of hindsight is less material in relation to the pain and discomfort associated with investigative procedures and the side-effects of drug therapy. These factors were available for observation at the time. The general information nevertheless also informs a proper appreciation of the accounts provided.

**13.151** Patients' reports of their individual histories are described in Chapters 4 and 6.

## CHAPTER 14

### KNOWLEDGE OF VIRAL HEPATITIS 1

#### Introduction

**14.1** Early developments in knowledge of viral hepatitis were noted in the introduction to Chapter 6 of the Preliminary Report. Key stages were:

- The discovery, in 1965, of the 'Australia' antigen, HBsAg, the surface antigen to the Hepatitis B virus (HBV), followed by the development of tests for the presence of the antigen, and subsequently other components of HBV, which became generally available from about 1970.<sup>1</sup>
- The identification of the Hepatitis A virus (HAV) by Dr Stephen Feinstone and others, published in 1973.<sup>2</sup>
- The realisation in around 1974–75 that Hepatitis A and Hepatitis B, as then understood, could not account for a substantial proportion of cases of post-transfusion hepatitis, and that there had to be another form or forms of viral hepatitis to explain the clinical manifestations of hepatic (liver) dysfunction that were known or becoming known.<sup>3</sup>

**14.2** In this Report, it is appropriate to discuss more fully the response of the UK Government and other agencies to the emerging knowledge of viral hepatitis during the period when it presented a threat to NHS patients receiving blood, blood components or blood products in the course of medical treatment.

#### Understanding the risk: background

**14.3** The aim of this part of the Report is to describe what was known at critical stages to scientists, practitioners and relevant authorities, not what 'ought' to have been known or accepted. In this early period, scientific developments were reported that, in time, became generally accepted medical knowledge. Developments can often be best identified and described chronologically, by date of publication, as was done in the Preliminary Report. However, inherent in this approach is a risk of representing as contemporaneous knowledge material that would not, and in some cases could not have, at that time, been known or understood by practitioners generally. Further, published data and discussion will reflect work carried out over a period prior to publication. In general, first publication of a finding or theory is more likely to mark the beginning of critical examination of ideas rather than the date of their general acceptance. Scientists exploring the boundaries of current knowledge inevitably develop theories that may be backed up by limited empirical data. Such theories are perhaps unlikely to meet with immediate acceptance by a critical peer group and even less likely to survive challenge by related, or unrelated, specialists. Scientific orthodoxy may resist novel ideas and inhibit their acceptance. Those with control of the funds necessary for the validation of a theory and the implementation of changes required to give practical expression to emerging ideas are even less likely to be easily satisfied.

---

<sup>1</sup> Preliminary Report paragraphs 6.12–6.14

<sup>2</sup> Ibid paragraphs 6.22–6.23

<sup>3</sup> Ibid paragraphs 6.28–6.32

**14.4** On the other hand, the convention that dictates that scientific ideas are presented tentatively where logical absolutes cannot be sustained should not be taken to undermine the impact of publication. Reputation is a significant factor of the author or authors of published work and of the journals in which they publish. It all makes for difficulty in saying when a given scientific proposition was 'established'. All of these comments are as relevant to the early 1970s as they are today.

### The early years

**14.5** The revolution in knowledge brought about by the discovery of the 'Australia' (or 'hepatitis-associated') antigen, later renamed the Hepatitis B surface antigen (HBsAg), the isolation of the Hepatitis A virus and the inference of the existence of one or more non-A, non-B Hepatitis (NANB Hepatitis) viruses can best be understood by looking in greater detail than was done in the Preliminary Report at some of the key early publications.

**14.6** Until the late 1960s, it was generally understood that 'hepatitis' could be transmitted in water-borne (enteral)<sup>4</sup> form or in blood-borne (parenteral)<sup>5</sup> form. It was thought likely that one or more agents causing enteral (also known as 'infectious') hepatitis were viruses and were different from the one or more agents – also thought probably to be viruses – which caused parenteral (also known as 'homologous' or 'serum') hepatitis. It was known that the development of serum hepatitis was associated with blood transfusion but it was thought that the hazard affected a very small proportion of recipients of whole blood, plasma or plasma products. In the mid-1960s, there was no single test or battery of liver function tests which would reliably distinguish carriers of any putative hepatitis virus from those not affected. The consequences of transmission, as understood at the time, varied:

Some patients suffer no upset from the transmitted virus, some may have only a transient liver dysfunction with or without jaundice and yet others may develop a rapidly fatal hepatic necrosis. The incubation period of infective hepatitis is about 20 to 40 days, whereas that of homologous serum hepatitis is 40 to 160 days.<sup>6</sup>

**14.7** The emphasis was on short-term signs and symptoms of infection and the two putative forms of hepatitis were distinguished by their periods of incubation before the appearance of clinical symptoms.

**14.8** A similar focus on the short term was reflected in early publications of the findings of haemophilia clinicians. Researchers in 1963 reported 'reactions' to the infusion of human AHG concentrate (a stable concentrate of human antihæmophilic globulin – a precursor to the industrial scale production of Factor VIII concentrates used for the treatment of haemophilia).<sup>7</sup> The reactions ranged from mild headaches to nausea, vomiting and pain. In all cases, the signs and symptoms of the reactions observed were reported to have disappeared quickly after the end of the infusion. These were almost certainly not related to the transmission of infection but rather were transient mild immune reactions to the 'foreign' proteins introduced by the AHG. The 1963 report also discussed three possible

<sup>4</sup> Strictly speaking, an enteral infection is one spread through the introduction of a pathogen to the gastrointestinal tract.

<sup>5</sup> Again, strictly speaking, a parenteral infection is one spread by a means other than by the introduction of a pathogen to the gastrointestinal tract and, in this general way, does not refer only to blood-borne infections. Medical literature of the time, however, used the term parenteral, at least as regards hepatitis, to mean 'blood-borne' and this usage is retained here.

<sup>7</sup> Maycock et al, 'Further Experience with a Concentrate Containing Human Antihæmophilic Factor', *British Journal of Haematology*, 1963; 9:215 [LIT.001.0063]. Dr Maycock and three of his colleagues were, at the time, associated with the Lister Institute of Preventative Medicine. One colleague was associated with the laboratory at Lewisham Hospital, London.

cases of homologous serum jaundice. It was said that no permanent harm was caused by the patients' reactions. The authors found that jaundice occurred but there was no firm view as to its cause. As with other adverse patient responses, it was not associated with apprehension of any long-term consequences of infection.

**14.9** Blood products were associated with a case of jaundice in a haemophilia patient reported in 1966,<sup>8</sup> and with a second, fatal case following the use of cryoprecipitate reported in September 1969.<sup>9</sup> The 1966 case was described as one of transient jaundice from which the patient recovered after a day of nausea and vomiting. The second case, of fulminant hepatitis (a rapidly progressing form of the disease), in retrospect almost certainly a case of fulminant Hepatitis B, presented after some four months of treatment using a total of 162 units of cryoprecipitate. The patient had developed nausea and continuous vomiting with cold, moist, jaundiced skin. He deteriorated rapidly and died. Post-mortem examination of the liver showed extensive hepatocellular damage. Tests for known viruses were carried out. Apart from a rather high titre (concentration) for cytomegalovirus (CMV), the samples tested were described as normal. Blood tested for serum hepatitis antigen, shortly to be called Hepatitis B antigen, gave a weak positive reaction. The conclusion was that the clinical and post mortem findings were 'fully compatible with a diagnosis of serum hepatitis'.<sup>10</sup>

**14.10** The report in 1969 stimulated correspondence. A letter published in the *British Medical Journal (BMJ)* in November of that year reported a further case with symptoms of nausea, itching and jaundice.<sup>11</sup> Biochemical laboratory tests disclosed high levels of alkaline phosphatase (ALP), and aspartate and alanine transaminase (AST and ALT).<sup>12</sup> A purported causal link between the use of concentrates and viral hepatitis was explicit in the letter but the focus remained on jaundice within a relatively short period after use of concentrates. More generally, the letter identified a need for screening for hepatitis infection to reduce transmission risk. It was recognised that, while careful questioning of donors would exclude those who had experienced clinical jaundice, effective reduction of risk depended crucially on a reliable test. The letter stated:

[U]ntil a reliable serological test for viral hepatitis is available the donor with anicteric hepatitis [hepatitis, that is, without jaundice] will go undetected. Cryoprecipitate will remain a potential source for the transmission of hepatitis virus until previous attacks of this form of hepatitis can be reliably diagnosed or an effective means of sterilization ... is produced.<sup>13</sup>

**14.11** The laboratory tests were not treated as diagnostic. The letter envisaged serum or viral hepatitis as a single entity requiring a single reliable serological test.

**14.12** There was a great deal of uncertainty at the time. The distinction between Hepatitis A and Hepatitis B was not fixed. Dr Rosemary Biggs, a prominent expert at the Oxford Haemophilia Centre, used the terms 'infective hepatitis' and 'viral hepatitis' interchangeably. An editorial in *The Lancet* in August 1970 cast doubt on the use of the terms 'serum' and 'infectious' to distinguish the two types envisaged at the time.<sup>14</sup> The

general state of uncertainty was reflected in a paper presented to the Sub-Committee of Specialists on Blood Problems of the Public Health Committee of the Council of Europe in April 1970, where it was commented that the generally observed distinction between Hepatitis A and Hepatitis B might be artificial.<sup>15</sup>

**14.13** For some official purposes, any distinction between infectious hepatitis and serum hepatitis was treated as irrelevant. In the UK, growing awareness of the prevalence of hepatitis led to provision for the notification of cases of the disease.<sup>16</sup> As regards Scotland, the Public Health (Infectious Diseases) Regulations (Scotland) 1932<sup>17</sup> required notification of infective jaundice, then defined to mean spirochaetosis ictero-haemorrhagica (Weil's disease). Those Regulations were amended by the Public Health (Infectious Diseases) (Scotland) Amendment Regulations 1968<sup>18</sup> after which the relevant notifiable disease was simply 'infective jaundice' without further definition.<sup>19</sup> It was intended that all forms of 'infective jaundice' (including 'serum' hepatitis) would be covered. One aim of the regulations was to facilitate a study of the epidemiology of the disease.<sup>20</sup> The scope of the 1968 Regulations is reflected in the incubation periods mentioned in the relevant Scottish Home and Health Department (SHHD) circular.<sup>21</sup> Infective hepatitis was said to have an incubation period of usually 15–40 days, while serum hepatitis was described as occurring less frequently but as a potentially more serious condition with a longer incubation period of usually 60–160 days. The focus was again on 'jaundice' and, apart from differing incubation periods, the symptoms of jaundice did not appear to give rise to any need to differentiate between infective hepatitis and serum hepatitis.

**14.14** The official view of the scope of the Regulations was not immediately accepted by all. Dr John Wallace of the Glasgow and West of Scotland Blood Transfusion Service (then and thereafter frequently a member of UK expert advisory groups) wrote to Dr Ian Macdonald of the SHHD, on 27 February 1969 asking for the official position on notification of serum hepatitis.<sup>22</sup> The response was that 'infective jaundice' was notifiable and that that included serum hepatitis.<sup>23</sup> For reporting purposes, then, a distinction between infective and serum hepatitis was not recognised by SHHD in these exchanges but it was agreed that the subject of notification was worthy of further consideration by the Transfusion Directors.<sup>24</sup> The Regional Blood Transfusion Directors subsequently proposed that the notification system should disclose the following:

Patients developing infective jaundice at a relevant period after having had blood or blood products.

[And]

Cases where patients are donors and who might have given blood whilst infected.<sup>25</sup>

**14.15** The emphasis on a 'relevant period' appears clearly to have implied that the reporting obligation would still extend only to cases of overt, clinical jaundice.

### UK research projects and reports

#### *Haemophilia Centre Directors' Report*

**14.16** The Directors of the (then) 36 Haemophilia Centres of Great Britain decided in 1967 to make a study of the incidence of transfusion hepatitis and inhibitors,<sup>26</sup> described as 'the two most alarming complications of treatment of patients with coagulation defects'.<sup>27</sup> During the years 1969 and 1970, before the ready availability of HBsAg screening tests, data were sought on the varieties and amounts of therapeutic materials used and on the incidence of 'inhibitors and jaundice'. On 5 April 1971 the results were presented to a meeting of the Haemophilia Centre Directors as a 'Report on the progress of the MRC Cryoprecipitate Working Party Survey of the Incidence of Transfusion Jaundice and the Incidence of Inhibitors in Haemophilic and Christmas Disease Patients'. The Inquiry has not found a follow-up from the Medical Research Council (MRC) to this particular report, although, as noted below (paragraphs 14.20–14.23), a Working Party of the MRC conducted its own research on recipients of blood transfusions at a single hospital in or around the same period. The relationship, if any, between this study and the later MRC study is not clear.

**14.17** The Haemophilia Centre Directors' report noted that transfusion-transmitted hepatitis was thought to be a viral infection and that there was every reason to suppose that the virus was contained in the various protein fractions used to treat haemophilia and Christmas disease (Haemophilia B), listed as cryoprecipitate, human antihemophilic globulin and Factor IX concentrate. It stated:

No attempt was made to record sub clinical hepatitis since the important feature from the point of view of these patients is clinical illness.<sup>28</sup>

**14.18** Of the 1066 patients reviewed in 1969, 34 had not been treated in the year, reducing the relevant cohort to 1032, in which 29 cases of clinical jaundice were recorded, an incidence of 2.8%. All of those patients were severely affected<sup>29</sup> by haemophilia or Christmas disease. The report contained detailed analyses of the materials used and the relationship between donor exposure and infection. The blood of 60 patients was tested for hepatitis associated antigen and antibody; and 11 tested positive, only one of which developed clinical hepatitis. The view expressed was that the overall low incidence of clinical illness was presumed to be due to the fact that the patients developed immunity in childhood. This led to the incorrect conclusion that patients with coagulation defects were very resistant to clinical infection with HBV. Lack of understanding of the natural history of the disease was a major contributory factor leading to incorrect inferences at this time (1971).

<sup>26</sup> Inhibitors are antibodies to Factor VIII. Haemophilia patients, particularly at this time, who developed inhibitors faced additional challenges in terms of therapeutic practice, as infusion of Factor VIII was not possible without serious risk.

<sup>27</sup> Appendix to Agenda for a Meeting of Haemophilia Centre Directors on 5 April 1971 entitled 'Report on the progress of the MRC Cryoprecipitate Working Party survey of the incidence of transfusion jaundice and Factor-VIII Antibodies in Treated Patients with Haemophilia and Christmas Disease' [DHF.001.1811] at 1812.

<sup>28</sup> Appendix to Agenda for a Meeting of Haemophilia Centre Directors 05/04/71 entitled 'Report on the progress of the MRC Cryoprecipitate Working Party survey of the incidence of transfusion jaundice and Factor-VIII Antibodies in Treated Patients with Haemophilia and Christmas Disease' [DHF.001.1811] at 1812

<sup>29</sup> See Chapter 2, *Patients at Risk*, paragraphs 2.24–2.27 for a discussion of the classification of haemophilia in to 'mild', 'moderate' and 'severe' categories.

**14.19** The results of the study were published by Dr Biggs in 1974.<sup>30</sup> By then, the text had been amended to cover the period 1969–71 and screening for HBV had been instituted. The study included 1837 patients, 62 of whom had 64 instances of clinical jaundice, an incidence of 3.48%. Again, most were severely affected haemophilia or Christmas disease patients. A total of 302 patients were tested by various methods for hepatitis associated antigen and antibody. About 30% were antigen or antibody positive. A smaller proportion was noticeably ill. The emphasis in the paper remained on clinically apparent hepatitis, typically manifested by jaundice.

#### ***Blood Transfusion Research Committee Cryoprecipitate Working Party***

**14.20** As noted above, the MRC Blood Transfusion Research Committee Cryoprecipitate Working Party conducted further research in the early 1970s to look into the relationship between transfusion and hepatitis in the UK. Members of the group included Professor Sheila Sherlock, Professor Ari Zuckerman, Dr William Maycock and Dr John Wallace. Its final report was published in 1974.<sup>31</sup> After excluding several groups of patients who fell out of the study for various reasons, 768 patients who had received blood transfusions at the Central Middlesex Hospital were studied intensively for six months after transfusion, both clinically and by laboratory tests for liver function.

**14.21** The overall incidence of icteric and anicteric hepatitis (that is, hepatitis with or without jaundice) was 1%. Of the 768 patients, eight were judged to have developed post-transfusion viral hepatitis on the criteria applied by the group. The study identified 35 other patients who showed ‘conspicuous or sustained’ elevated liver function (specifically, ALT) test results but were judged not to have symptoms or physical signs suggestive of viral hepatitis. A further 115 patients had ALT rises after transfusion but ‘were thought not to have viral hepatitis’.

**14.22** In discussing the criteria used for the diagnosis of hepatitis, the report stated:

Liver biopsy may provide incontrovertible confirmatory evidence of hepatitis but this procedure is seldom undertaken. Where liver biopsy was not performed, that is to say in the majority of the survey patients, reliance was placed on clinical evidence and measurement of serum ALT. The duration and degree of elevation of the enzyme that qualify a patient for inclusion in the hepatitis group must be critically examined. Neither a rise in ALT, nor its magnitude, is a specific indication of hepatitis. In some previous studies a transaminase level was arbitrarily defined below which a diagnosis of hepatitis was not made ... In the present survey no such arbitrary lower limit was set. However, if other factors were present which might have caused the enzyme rise these patients were not considered to be suffering from viral hepatitis; it was accepted that these other factors were a more likely cause of the liver damage ... This rigid exclusion of all patients having other possible causes for their liver damage may have contributed to the low incidence of hepatitis in the present study.<sup>32</sup>

**14.23** Other possible causes of an underestimate were also explored.

<sup>30</sup> Biggs, ‘Jaundice and antibodies directed against factor VIII and IX in patients treated for haemophilia or Christmas disease in the United Kingdom’, *British Journal of Haematology*, 1974; 26: 313–329 [LIT.001.0099]

<sup>31</sup> Medical Research Council Working party on Post-Transfusion Hepatitis, ‘Post-transfusion hepatitis in a London hospital: results of a two-year prospective study’, *Journal of Hygiene Cambridge*, 1974; 73:173–188 [LIT.001.0116]

<sup>32</sup> *Ibid* [LIT.001.0116] at 0127

**14.24** By 1974, the tests available for HBsAg and antibody to Hepatitis B (anti-HBs) remained relatively insensitive. The work of the MRC group was carried out in an era when overt clinical jaundice was still regarded as a good marker of 'post-transfusion hepatitis'. The existence of non-A, non-B Hepatitis (NANB Hepatitis) had yet to be reported and, therefore, the incidence of post-transfusion NANB Hepatitis virus infection could not have been, and was not, discussed. Though understandable in context, the firm exclusion of raised ALT without other clinical manifestations of infection as a diagnostic feature of viral hepatitis, even where there was no other indicator of liver inflammation, was to have a significant and continuing impact on the understanding in the UK of viral hepatitis generally.

**14.25** These studies represented significant initiatives in hepatitis research in the late 1960s and early 1970s. The approach adopted towards the identification of viral hepatitis in those studies would characterise UK research for a considerable period. As a result, in retrospect, the true incidence of post-transfusion hepatitis was underestimated. Dr Harvey Alter and Dr Leonard Seeff later analysed the data relating to the patients reported in the MRC Working Party study and concluded, in retrospect, that 80% of those with sustained elevated liver function test results had NANB Hepatitis, although in the original report the patients were not judged to have had 'post-transfusion hepatitis', as there defined, at all.<sup>33</sup> Arithmetically, if the report's assessment of HBV infection had been sound, the proportion of patients with NANB Hepatitis would have been even higher than indicated by Alter and Seeff.

**14.26** The MRC report represented the views of Professor Zuckerman and Professor Sherlock, both recognised at the time as authoritative commentators. In December 1975, the SNBTS Directors agreed with the main recommendations of the report when it was presented by Dr Wallace, a member of the group from the Glasgow and the West of Scotland Blood Transfusion Service.<sup>34</sup> In light of later knowledge, the MRC study was not a sound basis upon which one could draw conclusions about the prevalence of post-transfusion hepatitis in the UK, though it clearly represented informed opinion at the time. In his evidence to the Inquiry, Dr Brian McClelland, South East Scotland Blood Transfusion Service, stated that when he read the 1974 report in the early 1980s he realised that it did not tell transfusionists and others what they needed to know.<sup>35</sup> His efforts aimed at promoting research into the prevalence of post-transfusion NANB Hepatitis, against the resistance generated by established views, are discussed in Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*. The erroneous conclusion drawn from the study, that post-transfusion hepatitis was rare in the UK, persisted until 1980 and was promoted even later by some experts.

**14.27** At the same time as these studies were taking place, there were also developments at the UK Government level and internationally.

<sup>33</sup> Zuckerman and Thomas (eds), *Viral Hepatitis: Scientific Basis and Clinical Management* 1993; page 472, table 29.2. Ironically, it is possible that the MRC approach was influenced by the views of Professor Zuckerman.

<sup>35</sup> Day 63, page 71

## The Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen: First Report

**14.28** The Department of Health and Social Security (DHSS) responded promptly to advice received in July 1970<sup>36</sup> that it should give any assistance it could in instituting testing for the 'Australia' antigen. In September 1970 the three territorial Health Departments appointed the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen, to advise them on 'the organisation of and responsibility for testing blood donations and other specimens of blood for Australia (hepatitis-associated) antigen and its antibody in the hospital service' and related matters.<sup>37</sup> The initial members of the advisory group included some who would play a central role in the development of policy advice in the UK: Dr Maycock, the chairman, Dr David Dane,<sup>38</sup> Professor Albert Marmion (Edinburgh University Medical School), Dr Wallace (Glasgow and West of Scotland Blood Transfusion Service) and Dr, later Professor, Zuckerman.

**14.29** The Group published a first (revised) report in May 1972.<sup>39</sup> It set out the understanding of viral hepatitis of this group of experts at that date:

The association between the [hepatitis associated/Australia] antigen and serum hepatitis, commonly accepted as the most frequent form of hepatitis observed following the injection of blood and blood products, is well-established and the antigen can now be detected by a variety of laboratory tests .... Australia antigen appears not to be associated with infectious hepatitis which may also be transmitted by blood and blood products.<sup>40</sup>

**14.30** It was suggested that the 'hepatitis agent' might be less widely dispersed in the UK than in some other countries but it was nonetheless recommended that testing, for both the antigen and its antibody, should be introduced generally. The principal recommendations included:

[T]he Regional Transfusion Centres should begin, at the earliest possible date, to test all blood donations for the presence of Australia (hepatitis-associated) antigen and its antibody....

[And]

[A] donor found to be antigen or antibody positive should not be allowed to continue as a donor of blood intended for clinical use.<sup>41</sup>

## World Health Organization Scientific Group on Viral Hepatitis 25–30 September 1972

**14.31** Professor Zuckerman was a member of the Secretariat of the World Health Organization (WHO) Scientific Group on Viral Hepatitis, a body composed of eminent international experts, including Professor Marmion of Edinburgh. The report 'Viral

<sup>37</sup> Revised (first) Report of the Advisory Group on Testing for the Presence of Australia (Hepatitis Associated) Antigen and its Antibody [DHF.001.1980] at 1983

<sup>38</sup> Dr Dane led the team of scientists who, in 1970, discovered the complete Hepatitis B virus.

<sup>39</sup> Revised (first) Report of the Advisory Group on Testing for the Presence of Australia (Hepatitis Associated) Antigen and its Antibody [DHF.001.1980] at 1983

<sup>40</sup> Ibid [DHF.001.1980] at 1984

<sup>41</sup> Ibid [DHF.001.1980] at 2000

Hepatitis', Number 512 of the Technical Report Series, set the scene more widely and reflected an international understanding of the position.<sup>42</sup> The Introduction to the report indicated that the focus for the group was on viral Hepatitis A, epidemic or infectious hepatitis, and viral Hepatitis B, serum hepatitis. In comparison with the group's earlier reports, in 1953 and 1964, it was stated:

[B]ecause of the discovery of the Australia antigen in 1961<sup>43</sup> and its subsequent recognition as a specific marker of infection with the agent of viral hepatitis B, there has been great progress in the understanding of the clinical, epidemiological and immunological behaviour of this form of the disease. Relatively speaking there has been much less progress in the understanding of viral hepatitis A but there have been some advances ....<sup>44</sup>

**14.32** The report noted the change in terminology, from reference to 'Australia' as a descriptive term in describing the antigen and antibody, to the abbreviations 'HB Ag', and 'HB Ab', explaining that:

The terminology of the actual disease is more difficult. The general term viral hepatitis refers, by common usage, to hepatitis caused by two presumptive viruses, although it is recognised that other viruses may also be implicated.

It is proposed that the common forms of viral hepatitis be subdivided principally on epidemiological grounds, taking into consideration the presence of hepatitis B antigen, into:

Viral hepatitis type A,

and

Viral hepatitis type B.

There is substantial historical, epidemiological, and experimental evidence to suggest that these two types of hepatitis are caused by antigenically distinct agents. It is appreciated that it is not possible to allocate every patient with hepatitis to one of these two groups and that viral hepatitis infections exist that are due to other agents, only some of which have been recognised. This is a problem frequently confronting epidemiologists, clinicians, and pathologists that will only be resolved when the different etiological agents of hepatitis have been identified.<sup>45</sup>

**14.33** The clear inference from this discussion is that, while there were other aetiological agents, it was understood that the common forms of hepatitis were caused by what was called 'viral hepatitis type A' and HBV, although the Hepatitis A virus was not isolated until 1973. The characterisation of the most common forms of hepatitis as comprising (only) two aetiological groups was soon to be undermined.

<sup>42</sup> 'Viral Hepatitis: Report of a WHO Scientific Group', *World Health Organization Technical Report Series*, No. 512, 1973 [SGH.002.9746]

<sup>43</sup> 1961 is the date noted, but accurate dates for 'discovery' range from 1965 to 1967. See the quotation from Dr Cash at paragraph 14.56, below.

<sup>44</sup> 'Viral Hepatitis: Report of a WHO Scientific Group', *World Health Organization Technical Report Series*, No. 512, 1973 [SGH.002.9746] at 9750

<sup>45</sup> *Ibid* [SGH.002.9746] at 9751–9752

**14.34** The discovery of the Hepatitis B surface antigen, HBsAg, and demonstration of its persistence, resulted in the re-examination of theories and to the conclusion that HBV had a worldwide distribution similar to that previously attributed only to Type A. The report noted that there was developing understanding that not all cases of post-transfusion hepatitis were caused by HBV infection. It continued:

The proportion due to hepatitis B or other undesigned agents probably varies with the circumstances. However, as more hepatitis B carriers are eliminated from serving as blood donors, the proportion of cases due to other types of hepatitis will increase.<sup>46</sup>

**14.35** The report also commented:

The present widely employed techniques for detecting hepatitis B antigen in blood are thought to be capable of preventing approximately 30% of cases of post-transfusion hepatitis .... Cases not due to virus B are thought to be due to a variety of causes, including Hepatitis A virus, cytomegalovirus, and other, as yet unidentified agents.<sup>47</sup>

**14.36** These comments were an early and explicit recognition that there might indeed be other viruses, in addition to HBV, responsible for post-transfusion hepatitis.

**14.37** At the same time as the understanding of the serology and epidemiology of HBV infection was developing, the use of needle biopsy of the liver was becoming much more routine. Hence, for the first time, attempts could be made to correlate serological, biochemical and clinical features of a disease, Hepatitis B, with pathological features seen in the liver.

**14.38** The report defined a 'carrier state' of Hepatitis B, which might be associated with liver damage, as a persistent state in individuals in whom the antigen had been detected repeatedly for more than three months. A proportion of carriers had been found to have liver abnormalities ranging in severity from minor changes in the nucleus of the cell to severe hepatitis and cirrhosis:

Two forms of the chronic disease can be distinguished, persistent and aggressive. Clinically, chronic persistent hepatitis is a mild, benign disease, while chronic aggressive hepatitis tends to conform to the clinical syndrome of chronic active hepatitis, in which liver cell dysfunction is often severe and the prognosis is poor. However, considerable overlap exists between the clinical categories and their pathological counterparts. Aggressive changes may be seen in the course of uncomplicated acute viral hepatitis, but the prognosis in these cases is usually excellent.

Chronic persistent hepatitis is characterized ... by preserved lobular architecture, portal inflammatory infiltration, and slight or no fibrosis. It is not always preceded by a recognizable acute illness, and malaise, hepatomegaly and minor abnormalities of liver function are the clinical features. There is no progression to cirrhosis and the prognosis is good.<sup>48</sup>

---

<sup>46</sup> Ibid [SGH.002.9746] at 9754

<sup>47</sup> Ibid [SGH.002.9746] at 9762

<sup>48</sup> Ibid [SGH.002.9746] at 9757

**14.39** Discussing prevalence among blood donors, the report stated:

Great variations in the prevalence of hepatitis B antigen in apparently healthy blood donors have been found in different parts of the world. Prevalence also varies with such factors as the socioeconomic status and sex of the donor, whether he is a volunteer or paid, and whether he lives privately or in an institution. Antigen has been detected most frequently in males in the younger age-groups.<sup>49</sup>

**14.40** Further, the picture was changing at that stage:

During the past decade marked shifts in the age- and sex-specific rates for hepatitis have been observed in the USA and some European countries. These changes were subsequently found to be due to an increase in the number of Hepatitis B infections, particularly among males within the 15-29-year age group. The infections were not related to blood transfusion or other medical procedures. These features, together with the loss of seasonal peaks and the increasingly large proportion of urban cases suggested a likely association with the illicit use of drugs. It is quite possible that in addition to the increased risk of parenteral transmission, the mode of life of drug abusers may increase the level of non-parenteral transmission.<sup>50</sup>

**14.41** In addition to discussion of the epidemiology of hepatitis, the paper commented on changing perceptions of the relevance of a history of jaundice. Limited surveys had shown that the prevalence of Hepatitis B antigen was no higher amongst blood donors with a past history of jaundice than in those without such a history:

Studies of Hepatitis B infection among volunteers and those naturally infected with the virus suggest that a greater proportion of individuals who have had a mild or inapparent infection become chronic carriers of the antigen than those who have had a more severe illness. For this reason exclusion from blood donation of individuals with a clinical history of hepatitis B infection, but who do not have detectable antigen, may not materially reduce the frequency of hepatitis among the recipients of blood.<sup>51</sup>

**14.42** Dr McClelland commented that the 'more sensitive techniques' referred to in the report were actually 'very insensitive' and failed to detect many cases of Hepatitis B. In addition, while noting that there might be 'as yet other unidentified agents', the paper did not develop the risk that one or more might be responsible for significant transmission of infection. Dr McClelland said that the paragraph 'slightly confounded' the extent to which the techniques missed cases of Hepatitis B and their inability to detect non-B cases.<sup>52</sup> This was, nevertheless, an important juncture. The report was authoritative. It drew attention to the existence of a 'carrier state' and associated chronic liver disease, at least for HBV, which was not necessarily associated with a history of clinical jaundice. It provided a remarkable and, in many ways, prescient summary. It was the beginning of a move away from the exclusion of donors with a relatively distant history of hepatitis.<sup>53</sup> By 1973, therefore, to some extent at least, the idea that most post-transfusion hepatitis was attributable to HBV was already beginning to be superseded.

## The Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen: Second Report

**14.43** The WHO 1973 report was cited in an article on Hepatitis B in hospitals, published in 1974 by Dr Wallace and others.<sup>54</sup> The article quoted the suggestion that individuals with a history of overt hepatitis may not have a high incidence of HBsAg and commented that Dr Wallace had recently published evidence<sup>55</sup> supporting that contention. It was to have a more direct impact on the second report of the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen. The Group was reconvened on 6 December 1973 and reported in September 1975.<sup>56</sup> By then there had been a considerable advance in knowledge, including a second WHO technical paper, number 570, published in 1975.<sup>57</sup>

**14.44** Membership of the Advisory Group in 1975 comprised, among others, the individuals already mentioned in paragraph 14.28 as members of the original 1970 group. By that stage, the Australia (hepatitis-associated) antigen had become universally known as the Hepatitis B surface antigen. The second Advisory Group report discussed current knowledge of the antigen, HBsAg, its homologous antibody, anti-HBs, and the Hepatitis B core antigen-antibody system which was by then becoming recognised. The report stated:

The association between the presence of HBsAg in donor blood and the occurrence of HBsAg positive hepatitis in the recipients after an incubation period of 40-180 days is established. Blood and blood products can also transmit other forms of hepatitis which do not appear to be associated with the presence of HBsAg.<sup>58</sup>

**14.45** This second topic was not developed. It was thought likely that exclusion of HBsAg-positive donors would diminish the number of cases of Hepatitis B transmitted in blood and blood products, as it had in the USA.<sup>59</sup> It was also thought, on the basis of published reports, that the incidence of Hepatitis B in recipients of antibody-positive blood was no greater than that of recipients of blood in which neither HBsAg nor anti-HBs was demonstrable. The recommendations were amended to confirm the exclusion from clinical use of blood found to be HBsAg-positive but to recommend that donors whose blood contained anti-HBs might be retained on the panel and their blood used clinically.

**14.46** By the date of the second report, it was understood that Hepatitis B antibodies did not necessarily signal recovery from infection. The available evidence suggested that core antibodies might not be protective and that they were present in persistent carriers of HBsAg.<sup>60</sup> The association between HBsAg in donor blood and the occurrence of HBsAg-positive hepatitis in recipients was established.<sup>61</sup>

<sup>60</sup> *Ibid* [SGH.003.0079] at 0083

<sup>61</sup> *Ibid* [SGH.003.0079] at 0083

**14.47** The paragraphs from the WHO 1973 report are substantially paraphrased in the observations that:

Published reports show that the incidence of hepatitis B in recipients of antibody positive [blood] is no greater than that of recipients of blood in which neither HBsAg nor anti-HBs is demonstrable. Therefore... we now recommend that donors whose blood contains anti-HBs may be retained on the panel and their donations used clinically.

....

We have given much thought to the problem of donors with a history of jaundice but in whom neither HBsAg nor anti-HBs is detected. We are not aware of any evidence that a relationship exists between a history of jaundice in donors and the occurrence of icteric or anicteric hepatitis in recipients of their blood. We therefore recommend that the practice of permanently excluding from the panel donors with a history of jaundice should be discontinued provided that HBsAg is not detected by reversed passive haemagglutination or a test of at least equal sensitivity... and that the donor has not suffered from hepatitis or jaundice during the previous twelve months.<sup>62</sup>

**14.48** Individuals positive for HBsAg were to continue to be excluded from blood donation.

### Scotland

#### *The Joint Symposium of the Royal College of Physicians of Edinburgh and the Royal Society of Edinburgh*

**14.49** Scottish experts were represented on the panels reporting nationally and internationally, discussed above. In addition, there was more local study. A joint symposium was held in 1972 by the Royal College of Physicians of Edinburgh and the Royal Society of Edinburgh. The report of the joint symposium provides a base line for assessing Scottish views on many aspects of the topics under review at the start of the reference period.<sup>63</sup> The symposium was largely concerned with blood transfusion and therefore reflected a particular interest within the medical community related to the use of blood and blood products. The discussion also had wider relevance, however.

**14.50** Dr Robert Cumming, Regional Director of the Edinburgh and South East Scotland Blood Transfusion Service at the time, gave an introductory talk.<sup>64</sup> He discussed the prevention of adverse effects of transfusion, highlighting improvements in the equipment for handling blood, processing procedures and changes in practice aimed at minimising the traditional risks of incompatibility and bacterial contamination. However, diminishing risks of incompatibility had been offset by an increase in immune-system based risks arising from repetitive transfusion.<sup>65</sup> He referred to, but did not discuss, the detection of diseases transmissible by blood. He emphasised the need for greater knowledge of the dangers inherent in the intensive use of 'potent therapeutic agents of biological origin'.<sup>66</sup>

<sup>62</sup> Ibid [SGH.003.0079] at 0084–0085

<sup>63</sup> *Proceedings of the Royal Society of Edinburgh Section B (Biology) 1972*; vol 71 Supplement [PEN.002.0407]

<sup>64</sup> Ibid [PEN.002.0407] at 0408

<sup>65</sup> This phenomenon was to re-emerge in the 'antigen overload' theory, developed in the early 1980s as an alternative to the 'infective agent' theory of AIDS. See Chapter 9, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 1*.

<sup>66</sup> *Proceedings of the Royal Society of Edinburgh Section B (Biology) 1972*; vol 71 Supplement [PEN.002.0407] at 0410.

**14.51** Professor Alexander Douglas, Regius Professor of Medicine at Aberdeen University, discussed the use of plasma coagulation factors. His comments on possible adverse effects of therapy were brief:

Side-effects to factor VIII include febrile reactions, the transmission of serum hepatitis and the induction of antibodies to factor VIII .... Using human factor VIII preparations the risk of hepatitis is proportional to the number of donations involved in the material given. In the production, for example, of cryoprecipitate the blood should be screened for Australia antigen.<sup>67</sup>

**14.52** On the other hand, while plasma therapy for Haemophilia B patients was associated with non-specific reactions, in Scotland prothrombin therapy (for Haemophilia B) using concentrated materials was thought to be problem-free.<sup>68</sup>

**14.53** These contributions by Dr Cumming and Professor Douglas reflected similar interests to those investigated by Dr Biggs. Dr Wallace promoted the advantages of pasteurised albumin product (Plasma Protein Solution) as the product of choice thanks to the heating process involved in its manufacture.<sup>69</sup> It could be presented in stable liquid form as Stable Plasma Protein Solution (SPPS), pasteurised at 60°C for 10 hours, and in that form it was said to be free from the risk of transmitting viral diseases, thus eliminating the hazard of hepatitis. He noted that in general surgery there was progress towards the use of blood components in preference to whole blood. A policy of total fractionation (the division of blood in to its component parts) was advocated as the ideal towards which transfusion services should aim.

**14.54** However, it was in the presentation of Dr John Cash,<sup>70</sup> then Deputy Director of the Edinburgh and South East Scotland Blood Transfusion Service, that the risk of hepatitis transmission was most clearly identified.

**14.55** By way of introduction, he wrote:

Although the medical profession has long recognised the concept that there are no therapeutic roses without thorns, there is no doubt that the dangers of blood transfusion, in all its forms, have yet to be fully defined. However, in the ardour of therapeutic endeavour, we are frequently guilty of forgetting those hazards which have already been well documented ....

Recent data published by the Registrar General (1971) would suggest that the numbers of deaths attributable to blood transfusion are comparable to those complicating general anaesthesia. Almost 50 per cent of the post-transfusion deaths were due to hepatitis. While not intending to underemphasise the importance of incompatible red cell, white cell and platelet transfusions, allergic reactions to plasma proteins, systemic effects of bacterial pyrogens and heavily contaminated blood and blood products, air embolism, citrate intoxication and haemosiderosis, the magnitude of the hepatitis problem and the recent explosion of highly productive research in this area is so great that it

<sup>67</sup> Douglas, 'Plasma Coagulation Factors', *Proceedings of the Royal Society of Edinburgh 1972*; Section B (Biology), vol 71 Supplement [PEN.002.0575] at 0578

<sup>68</sup> *Ibid* [PEN.002.0575] at 0579

<sup>69</sup> Wallace, 'New Approaches to the Supply of Blood and Plasma', *Proceedings of the Royal Society of Edinburgh 1972*; Section B (Biology) vol 71 Supplement [PEN.018.1026] at 1029

<sup>70</sup> Cash, 'Principles of Effective and Safe Transfusion', *Proceedings of the Royal Society of Edinburgh 1972*; Section B (Biology), vol 71 Supplement [PEN.002.0559]

seems appropriate on this occasion to consider this particular feature of safety in some detail.<sup>71</sup>

**14.56** Apart from demonstrating considerable literary panache, Dr Cash's assessment of the problem of hepatitis, as then understood, placed it squarely before the medical profession in Scotland. His discussion is, therefore, of particular importance in defining the scope of general knowledge of the risk at this time. He continued:

In 1965, Blumberg *et al* (1965) reported that sera from two multi-transfused haemophiliac patients formed precipitin lines in the micro-Ouchterlony gel diffusion test when tested against serum from an Australian aborigine. The substance in this serum did not appear to be the usual lipoprotein and was tentatively labelled 'Australia antigen'. Subsequent studies revealed that the presence of Australia antigen was closely associated with viral hepatitis (Blumberg *et al*, 1967; Blumberg *et al*, 1968; Prince 1968), and that virus-like particles could be isolated from antigen-positive sera (Bayer *et al*. 1968). Confirmation of these findings came from all over the world along with the observation by Okochi and Murakami (1968) which clearly indicated that hepatitis frequently followed the transfusion of antigen-positive blood.

These primary observations heralded an explosive research effort in which clinicians, biochemists, geneticists, microbiologists and immunohaematologists have all made important contributions.<sup>72</sup>

**14.57** After citing a range of publications on specific issues, which emphasised the familiarity of the NHS in Scotland at this early stage with world-wide research, Dr Cash proceeded:

From the early beginnings of this work, debate has gone on as to whether Australia antigen is responsible for serum hepatitis alone or both infectious hepatitis and the serum form of this disease. Recent work has shown that the classical long incubation (serum) form, while more commonly acquired by the parenteral route, can also be transmitted orally. This suggests that Australia antigen is responsible for the classical serum hepatitis and sporadic cases of infectious hepatitis and that other agents are casually [*sic* – causally] related to epidemic infectious hepatitis (Simon 1971). However, there seems little doubt that the agents responsible for the epidemic variety can be transmitted parenterally and, therefore, by means of blood transfusion (Koff and Isselbacher 1968).

In 1968, Okochi and Murakami first suggested a possible relationship between hepatitis and the administration of Australia antigen-positive blood. This observation was confirmed by Gocke and Kavey (1969) and both groups have confirmed and extended their original findings (Gocke *et al*. 1970; Okochi *et al*. 1970).<sup>73</sup>

<sup>72</sup> Ibid [PEN.002.0559] at 0563

<sup>73</sup> Ibid [PEN.002.0559] at 0564

**14.58** This review was written before Feinstone and Prince's work enabled the provision of markers for HAV and before the publication of evidence for one or more NANB Hepatitis viruses that followed.<sup>74</sup> It appears that, while the presentation contained a number of assertions not ultimately established, the medical profession in Scotland was made aware that (i) there was a causal relationship between transfusion and hepatitis infection; (ii) the Australia antigen/HBsAg was not solely responsible for the transmission of hepatitis infection; and (iii) post-transfusion hepatitis was fatal in some cases. In common with other parts of the UK, some trends in research that were to mark step changes in understanding of viral hepatitis in the USA were not taken into account.<sup>75</sup> It nevertheless appears to be clear that, at the beginning of the reference period, the NHS in Scotland was aware of international research on Hepatitis B and, indeed, was participating in it.

### *Local research*

**14.59** Scottish scientists had certainly played a part in developing knowledge of viral hepatitis, however. By 1970, the Blood Transfusion Centres in Edinburgh and Glasgow had started research on hepatitis.<sup>76</sup> In the case of the Glasgow study, this was a direct response to the 1970 WHO Bulletin recommending the detection and exclusion of blood donors carrying Australia antigen.<sup>77</sup> The study distinguished donors tested for the first time and those returning who had previously tested negative. The reported incidence of 0.115% for the general donor population on first testing was in agreement with the general level of about 0.1% for unpaid donors in the USA and in Western Europe. The Glasgow researchers recognised that their test was relatively insensitive and commented that it was 'too early to assess the full significance of total screening ...'. A contemporaneous study on behalf of the National Blood Transfusion Service (N BTS) for England and Wales found that the incidence of Hepatitis B antigen in donations from new general public and factory donors in 1973 was 1:1107 (0.09%).<sup>78</sup> Routine blood screening for what became known as HBsAg and its antibody, Anti-HBs, was instituted in 1974.

**14.60** In Edinburgh, systematic study of bleeding patterns in haemophilia patients began in the 1960s and 1970s and progressed to the study of risks of virus transmission, initially focused on HBV.<sup>79</sup> These studies continued into the 1980s.<sup>80</sup> They were initiated by Dr Howard Davies of the Edinburgh Haemophilia Centre and Dr John Peutherer, a virologist; Professor Christopher Ludlam became involved when he succeeded Dr Davies.<sup>81</sup> During the early 1970s it was found that, despite screening, about 10% of susceptible patients became infected each year with HBV but that only a tiny proportion of these became infective HBV carriers.<sup>82</sup> Until the end of the 1970s, screening tests for HBsAg were not sensitive enough to detect all blood donations infected with HBV.

**14.61** The incidence of anti-HBs in haemophilia patients suggested that a significant proportion had become infected by HBV. Dr Biggs' 1974 paper, discussed above (paragraph 14.19), recognised that factor concentrates generally were associated with a risk of transmitting hepatitis.<sup>83</sup> Others were more definite in their conclusions. Writing in 1974, Dr Donald Buchholz said that, 'hepatitis reigns supreme as the major cause of transfusion-associated disease'.<sup>84</sup>

**14.62** Dr Biggs' 1974 review also noted that post-transfusion hepatitis was caused by several viruses which might occur in donor plasma and hence in the various protein fractions used to treat haemophilia and Christmas disease. The ability to identify both the Hepatitis B antigen and antibody enabled scientists to estimate the proportion of cases of post-transfusion hepatitis associated with Hepatitis B, within the limits of sensitivity and specificity of the tests available from time to time.

### Research in the United States of America

**14.63** It is appropriate at this point to take note of research that had not entered into the UK reports already discussed. Research projects in the USA in the early to mid-1970s, led by Alter, Aach, Knodell and Seeff, led to a conclusion by 1974–75 that Hepatitis B, the main focus of attention in the UK, was responsible for only a low proportion of transfusion-associated hepatitis. This research is discussed in more detail in the next chapter (Chapter 15, *Knowledge of Viral Hepatitis 2*).

**14.64** The Hepatitis A virus, responsible for most enteric hepatitis was identified in 1973 by Feinstone and others.<sup>85</sup> At that time, however, there were still no blood tests to detect either its presence in the blood or the fact that an individual had been exposed to the virus but subsequently cleared it. That development would come in 1974–75. At the beginning of the reference period, in 1974, scientists were approaching a critical change in understanding that would lead to the identification of forms of hepatitis that were neither form A nor form B, but that stage had not yet been reached.

### Towards non-A, non-B Hepatitis/Hepatitis C

**14.65** Following the opinion that Hepatitis B accounted for a relatively small proportion of cases of post-transfusion hepatitis, doubts grew on epidemiological grounds over whether Hepatitis A could account for the majority of cases of post-transfusion hepatitis as was implied in earlier discussion.<sup>86</sup> In 1974, Alfred Prince and others suggested that a substantial proportion of post-transfusion hepatitis cases were caused neither by the Hepatitis A virus nor by the Hepatitis B virus and they suggested the existence of an additional hepatitis virus or viruses which would require 'identification of a hepatitis virus(es) type C'.<sup>87</sup> It was to be long before the term 'Hepatitis C' entered the vocabulary but Dr Prince and colleagues had clearly noted the need for differentially identified types of hepatitis virus in their original work.

<sup>83</sup> Biggs, 'Jaundice and antibodies directed against factor VIII and IX in patients treated for haemophilia or Christmas disease in the United Kingdom', *British Journal of Haematology*, 1974; 26: 313–329 [LIT.001.0099]

<sup>84</sup> Buchholz, 'Blood Transfusion: Merits of Component Therapy', *The Journal of Pediatrics*, 1974; 84: 165 [LIT.001.0141] at 0145

<sup>85</sup> Feinstone et al, 'Hepatitis A: Detection by Immune Electron Microscopy of a Viruslike Antigen Associated with Acute Illness', *Science*, 1973; 182:1026 [PEN.010.0110]

<sup>86</sup> Preliminary Report, paragraph 6.28

<sup>87</sup> Prince et al, 'Long-Incubation Post-Transfusion Hepatitis Without Serological Evidence of Exposure to Hepatitis-B Virus', *The Lancet*, 3 August 1974 [LIT.001.0363]

**14.66** The identification of the specific Hepatitis A virus by Stephen Feinstone's team provided a basis for proof of Prince's hypothesis.<sup>88</sup> Serological analysis in 1975 of stored sera from the earlier studies revealed that none of the cases of transfusion-associated hepatitis could be attributed to HAV.

**14.67** Following this work, the expression 'non A, non B hepatitis' (frequently abbreviated to 'NANBH' or 'NANB Hepatitis') was coined as a collective term for hepatitis from which, at that time, Hepatitis A and Hepatitis B, as well as CMV and Epstein-Barr virus (both of which can cause liver inflammation), had been excluded.<sup>89</sup> In due course, and much later, further research led to the identification of the Hepatitis C virus as the principal cause of the condition described.<sup>90</sup> As at 1974, knowledge of HAV, HBV and NANB Hepatitis infection was not developed and was not widely disseminated. Awareness of the risk of viral infection from blood and blood products was relatively unrefined and unsophisticated.

**14.68** There is a serious risk, in citing the work of researchers such as Feinstone and Prince, of giving the impression that their ground-breaking research immediately entered the common currency of general medical knowledge and informed clinical practice. That would be as unfair as it would be unrealistic. The view that there were only two relevant hepatitis viruses had support in the UK in the 5th edition of Professor Sherlock's book, *Diseases of the Liver and Biliary System*, published in 1975. The book can be taken to provide an authoritative description of the state of knowledge available to the medical profession in the UK generally in 1974–75.<sup>91</sup> Hepatitis A was not identified as a separate cause of concern; despite Professor Sherlock's observation that the disease might be transmitted parenterally, it was not thought to be associated with transfusion.<sup>92</sup> Hepatitis B was described as a 'long incubation disease'. It was said to be spread classically by therapeutic administration of blood and blood products but could also be spread orally and sexual spread was considered likely.<sup>93</sup> The 5th edition contained no reference to the NANB Hepatitis virus.

### ***Diseases of the Liver and Biliary System (1975)***

**14.69** Professor Sherlock's description of the clinical course of hepatitis included the following comments:

Hepatic involvement, particularly to the extent of jaundice, is an *infrequent* complication of rather a common virus infection. The picture varies widely, ranging from slight malaise to a severe and fatal disease culminating in hepatic coma ....

In general, type A and type B hepatitis run the same clinical course. Type B tends to be more severe and may be associated with a serum sickness-like syndrome. The relationship of type B to chronic liver disease has been established ....

<sup>88</sup> Though published first, Feinstone's work is said to have been later in date (see, for example, *Viral Hepatitis: Scientific Basis and Clinical Management* ed Zuckerman and Thomas: 1993 page 470) but this must be questioned in view of the citation in the Prince paper of one paper read at the 6th symposium of the American Red Cross in May 1974. See the Preliminary Report, paragraph 6.29.

<sup>89</sup> See, for example, Alter et al, 'Clinical and serological analysis of transfusion-associated hepatitis', *The Lancet*, 1975; 2: 838–841 [LIT.001.3926] where Cytomegalovirus (CMV) and Epstein-Barr Virus (EBV) were excluded as causal agents of NANB Hepatitis.

<sup>90</sup> Identified by the Chiron Corporation in spring 1988 and announced on 10 May 1988. See Chapter 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards*. In the mid 1970s, the position was not clear. A letter to *The Lancet* of 16 November 1974 by Fiala and others of California and two Abbott workers, Overby and Ling, in response to Prince, suggested that more work was required on the possible role of cytomegalovirus in hepatitis. Fiala et al, 'Cytomegalovirus in non-B post-transfusion hepatitis', *The Lancet*, 16 November 1974 [LIT.001.3930]

<sup>91</sup> Later editions remained authoritative while Professor Sherlock was general editor.

<sup>92</sup> Sherlock, S. *Diseases of the Liver and Biliary System*, 5th ed. 1975, Blackwell, Oxford, page 305

<sup>93</sup> *Ibid* page 306

The severity is very variable. The mildest attack is without symptoms and marked only by a rise in serum transaminase levels. If it is of type B there is transient HBAg positivity. Alternatively, the patient may still be anicteric but suffer gastro-intestinal and influenzal-like symptoms ....

The usual icteric attack in the adult is marked by a prodromal period usually about 3 or 4 days but even up to 2 or 3 weeks.

....

The prodromal period is followed by darkening of the urine and lightening of the faeces. This heralds the development of jaundice and symptoms decrease .... Appetite returns and abdominal discomfort and vomiting cease. Pruritus [itching] may appear transiently for a few days.

....

The adult loses about 10 lb weight. A few vascular spiders may appear transiently.

After an icteric period of about 1–4 weeks the adult patient makes an uninterrupted recovery .... After apparent recovery lassitude and fatigue persist for some weeks. Clinical and bio-chemical recovery is usual within 6 months of onset.<sup>94</sup>

**14.70** Professor Sherlock noted the possibility of prolonged jaundice, also followed by complete recovery, and commented on 'post-hepatitis syndrome' as a condition leaving the patient feeling 'below par' for weeks or months.<sup>95</sup> She commented that chronic persistent hepatitis, chronic active hepatitis, post-hepatitic scarring and cirrhosis could all develop.<sup>96</sup> Of these, the author described chronic persistent hepatitis as benign. She continued:

*Chronic active hepatitis* often proceeds to or is associated with cirrhosis. Chronic active hepatitis also has many causes. The mechanism by which hepato-cellular necrosis proceeds in any individual to chronic active hepatitis and finally to the irreversible stage of cirrhosis is in most instances unknown. Knowledge of the factors determining this course would give the key to the development of cirrhosis.<sup>97</sup>

**14.71** For comparison, the observations of Prince and others in their 1974 paper are noteworthy. The authors suggested, albeit tentatively, that there were long-term risks associated with Hepatitis B and non-B viruses:

Long-term complications of acute hepatitis-B infection, such as chronic hepatitis, cirrhosis, and hepatoma, have been reported to follow mild anicteric infections more frequently than severe icteric cases; consideration must thus also be given to the possibility that non-B hepatitis may play a role in the aetiology of some forms of chronic liver disease.<sup>98</sup>

<sup>94</sup> Ibid page 321-322 (emphasis in original)

<sup>95</sup> Ibid page 324

<sup>96</sup> Ibid page 333

<sup>97</sup> Ibid page 390

<sup>98</sup> Prince et al, 'Long-Incubation Post-Transfusion Hepatitis Without Serological Evidence of Exposure to Hepatitis-B Virus', *The Lancet*, 3 August 1974 [LIT.001.0363] at 0368

**14.72** Notwithstanding these differences, Professor Sherlock's analysis would have been understood by most, if not all, clinicians in the UK to be an authoritative exposition of knowledge of viral hepatitis at the beginning of the reference period.

### **Knowledge of blood-borne hepatitis at the outset of the reference period:**

#### **Summary**

**14.73** Knowledge of blood-borne hepatitis was rudimentary in the early 1970s. The results of reported studies were just beginning to make an impact on thinking among scientists at the leading edge of research. Among clinicians generally, Professor Sherlock's views would have been definitive of the state of knowledge. In other respects, there was uncertainty:

- The work of Blumberg and others initiated a new era of research but knowledge of hepatitis and the forms recognised at the time remained incomplete.
- Routine (fairly sensitive) testing for HBsAg in all donor blood meant that from this time new cases of post-blood transfusion hepatitis caused by HBV would become rare in the UK, although that would become clear only later.
- Early surveys with relatively insensitive tests suggested that the prevalence of HBsAg positivity was about 1:1000 of the donor population in Scotland and England.
- The fact that at least 20% of haemophilia patients treated with clotting factor had markers of past infection with HBV was recognised.
- Serum markers of HBV in routine use were still confined to HBsAg – correctly thought to be an indicator of potential infectivity – and anti-HBs – correctly thought to indicate past infection with HBV and to indicate immunity from further infection as well as lack of infectivity.
- Understanding of the natural history of HBV infection, and particularly of the groups at risk of developing chronic HBV infection, was still poorly developed.
- Factor therapy had become more and more popular with haemophilia patients and their doctors<sup>99</sup> and there was a consequent significant increase in demand on the supply of blood from which these factors were extracted.<sup>100</sup>

---

<sup>99</sup> In 1974 Peter Jones, a Haemophilia specialist, published *Living with Haemophilia* (Lancaster: Medical and Technical Publishing Co. Ltd). This was written as an introductory guide to haemophilia for haemophilia patients and their families, and reflected the contemporaneous views of haemophilia groups.

<sup>100</sup> See Spencely & Cash, 'Factor VIII replacement in the treatment of haemophilia A – a simple illustration of a need-supply-demand spiral', *British Journal of Preventative Medicine*, 1974; 28: 71 [LIT.001.0149]

**14.74** Matters that were just beginning to be reported yet had a significant impact on knowledge in the UK were:

- Recognition that HBV accounted for only a relatively small proportion of cases of post-transfusion hepatitis was beginning to be reported.
- HAV had been discounted as a cause of most post-transfusion hepatitis infections following Feinstone's characterisation of the virus and the development of serological tests for it.
- The term NANB Hepatitis was coined for hepatitis from which, at that time, HAV and HBV, CMV and Epstein-Barr virus had been excluded as causative agents.
- Prince and colleagues had already reported that long term complications of acute Hepatitis B infection, such as chronic hepatitis, cirrhosis and hepatoma, appeared to have followed mild anicteric infections more frequently than severe icteric cases.
- However, the prevalence of what would become NANB Hepatitis was not known, and there was no understanding of its natural history or of its epidemiology.

## CHAPTER 15

### KNOWLEDGE OF VIRAL HEPATITIS 2 – 1975 TO 1985

#### Introduction

**15.1** This chapter will trace developments in the understanding of viral hepatitis from 1975 to around 1985. As noted at the end of the last chapter, at the end of 1974 expert views published widely in the UK on the aetiology and natural history of viral hepatitis did not reflect developing understanding of the disease in the USA. In this period there were continuing differences in the timing of general acceptance of emerging theories. There were also differences between UK and US sources in the definition of the markers of non-A, non-B Hepatitis (NANB Hepatitis) infection. These differences had a material bearing on the perception of the prevalence of infection in the UK and, correspondingly, of the risks potentially associated with transfusion of blood, blood components and blood products.

**15.2** While much of the information from this period is taken from published sources which were available, at least to relevant experts in their particular fields of study, it is apparent that there were also informal exchanges of information among researchers. For example, on 6 January 1975, Dr J Garrott Allen of the Stanford University Medical Centre wrote to Dr William Maycock, Director of the National Blood Transfusion Service (NBTS).<sup>1</sup> The substance of the letter and Dr Allen's wider involvement in the assessment of risk in the UK are discussed later.<sup>2</sup> It is an example of written communication. More frequently, telephone exchanges and discussion at international conferences maintained the dialogue. It would not be correct to assume that UK experts were entirely unaware of what was happening elsewhere, particularly in the USA.

**15.3** However, between the USA and European countries, including the UK, there were differences in response to emerging knowledge at certain stages. In the background, there was probably a lower prevalence of NANB Hepatitis infection in the UK as a whole than in the USA and the perception that this was the case appears clearly to have influenced opinion. It is therefore appropriate to deal with the bodies of research material from the USA separately from other sources, at least to the end of this period.

**15.4** In this chapter, US research dating from the mid-1970s to about 1981 will be described first. By that stage, some firm views had emerged on the prevalence of NANB Hepatitis as understood in the USA. Progress in UK research over approximately the same period, where there was a different view of the diagnostic features of NANB Hepatitis, will be described next. Thereafter, discussion will focus on the second half of the period, 1980–81 to about 1985, but including publications from 1986 which related to the first half of the decade.

## Viral hepatitis mid-1970s to 1981

### *Aetiology and natural history of NANB Hepatitis: research in the United States of America*

**15.5** For present purposes, it is not necessary to trace in any detail the general history of developments in the knowledge and understanding of hepatitis before about 1973–74. One series of studies on post-transfusion hepatitis in open-heart surgery patients at the National Institutes of Health (NIH), initiated in 1965 and led by Dr Harvey Alter, was to play a major part in developing knowledge, however.<sup>3</sup> Together, these studies reflect the views of a group of respected researchers working after Blumberg's seminal work on the Australia antigen,<sup>4</sup> and before the published work of Prince, Feinstone and others on the prevalence of Hepatitis A in post-transfusion hepatitis, discussed below, that led to the conclusion that one or more non-A, non-B hepatitis viruses were implicated in post-transfusion hepatitis. The initial 1965 study demonstrated that there was a high risk of transmission of icteric and anicteric hepatitis (that is, hepatitis with or without clinical jaundice) associated with commercial blood. The second study, begun in 1968, demonstrated that there was a high risk of developing hepatitis from receiving blood contaminated with Hepatitis B surface antigen (HBsAg): half of the patients infected developed icteric hepatitis. By 1970, when the third study began, it had become feasible to fulfil blood requirements solely from volunteer sources and to screen donor blood prospectively for HBsAg. The study examined the effect of the combined exclusion of all commercial and voluntary HBsAg-positive donations. It was concluded that the exclusion of all commercial and volunteer blood donors testing positive for the HBsAg, significantly reduced the rate of transmission of hepatitis.

**15.6** As noted in paragraphs 14.32–14.36 of the last chapter, research projects in the USA up to the mid-1970s led to a conclusion that the Hepatitis B virus (HBV) was responsible for only a small proportion of the residual cases of transfusion-associated hepatitis. Research based on cardiac patient groups continued and by 1975 the conclusion on HBsAg was more broadly and starkly expressed in an article by Stephen Feinstone and others:

The preponderance of hepatitis after blood transfusion is unrelated to the hepatitis B virus.<sup>5</sup>

**15.7** By 1974–75 it was also understood that Hepatitis A was not implicated to any material extent in post-transfusion hepatitis.

### New York University Hospital

**15.8** Opinion had quickly developed to reach that point, however, and it is appropriate to begin the account at a slightly earlier date, with the article by Alfred Prince and others referred to in the last chapter at paragraph 14.65.<sup>6</sup> The reported research project involved 299 patients. They had undergone major surgery (mostly cardiovascular surgery) at New York University Hospital between May 1969 and August 1972 and presented as an intensively-managed group of patients available for research across a broad front.

<sup>3</sup> Alter et al, 'Posttransfusion Hepatitis After Exclusion of Commercial and Hepatitis-B Antigen Positive Donors', *Annals of Internal Medicine*, 1972; 77: 691-699 [PEN.002.0811]

<sup>4</sup> See Chapter 14, *Knowledge of Viral Hepatitis 1*.

<sup>5</sup> Feinstone et al, 'Transfusion-associated hepatitis not due to Viral hepatitis Type A or B', *New England Journal of Medicine* 1975; 767-770 [LIT.001.0137]

<sup>6</sup> Prince et al, 'Long-Incubation Post-Transfusion Hepatitis Without Serological Evidence of Exposure to Hepatitis-B Virus', *The Lancet*, August 3 1974 [LIT.001.0363]

**15.9** Blood sera from the patients were tested for HBsAg or Hepatitis B antibody (anti-HBs) and serum-transaminases<sup>7</sup> were measured. All cases with transaminase abnormalities were reviewed by a panel of clinicians, to exclude cases likely to have causes of liver-function abnormality other than post-transfusion hepatitis. 'Hepatitis' was defined as two or more consecutive elevations of serum-transaminase above the upper limit of normal when tested internally or, if tested by an outside laboratory, 2.5 times the upper limit of normal applied by that laboratory, all within specified time limits. This was an approach typical of US researchers at the time. Follow-up was completed for 204 patients. Hepatitis, as defined, was developed in 51 and jaundice in 21. Of the hepatitis cases, 15 showed exposure to Hepatitis B virus by HBsAg or anti-HBs response. A Hepatitis B response without developing hepatitis, as defined, was shown in 25 more. The conclusion of the article, as summarised, was:

An agent other than hepatitis-B (HB) virus seemed to be the cause of 36 (71%) of 51 cases of post-transfusion hepatitis identified during prospective biweekly serological follow-up of 204 cardiovascular-surgery patients. The sera of the 36 cases showed no evidence of the antigen or antibody response expected to accompany infection by HB virus and to be detectable by the sensitive assays used. Incubation periods and clinical and epidemiological features were inconsistent with Hepatitis A. Cytomegalovirus-associated seroconversion was no more common among the HB-negative cases than among HB-positive cases or among patients who did not develop hepatitis. The data suggest that a large proportion of long-incubation post-transfusion hepatitis is unrelated to Hepatitis B ....<sup>8</sup>

**15.10** The paper sought to demonstrate that the condition described was probably not Hepatitis A or Hepatitis B and inferred that the cause was some other, as-yet unidentified virus. This agent proved to be elusive and defied many wide-ranging efforts to identify it. As noted in paragraph 14.71 of the last chapter, the article also commented on the risk that the condition might be associated with progressive liver disease and long-term complications such as chronic hepatitis, cirrhosis, and hepatoma.

### National Institutes of Health

**15.11** The article by Feinstone and others, published in April 1975 and cited in paragraph 15.6 above, took matters further, and examined 22 patients. The team had continued their work on patients who had received corrective cardiac surgery, covering patients treated at the National Institutes of Health. They postulated that a viral agent, other than the Hepatitis A virus (HAV) or HBV but yet to be identified, was commonly transmitted by blood transfusion and caused hepatitis. The patients in this cohort were selected for study because a diagnosis of hepatitis was well established, serial serum samples were available and HBsAg had not been detected in acute-phase serum samples obtained from them. Hepatitis was defined by transaminases 2.5 times the upper limit of normal within specified time limits and the exclusion of other possible causes for elevated levels of transaminases. The method of identifying Hepatitis A antibody described by Feinstone and others in 1973 was applied.<sup>9</sup>

<sup>7</sup> Proteins synthesised in liver cells, normally present in low levels in the blood, which become elevated when the liver is disordered by virus infection or other disorders of the liver.

<sup>8</sup> Prince et al, 'Long-Incubation Post-Transfusion Hepatitis Without Serological Evidence of Exposure to Hepatitis-B Virus', *The Lancet*, August 3 1974 [LIT.001.0363]

<sup>9</sup> Feinstone et al, 'Hepatitis A: Detection by Immune Electron Microscopy of a Viruslike Antigen Associated with Acute Illness', *Science*, 1973; 182:1026 [PEN.010.0110]

**15.12** Some of the patients had been exposed to the HAV before transfusion. However, nine patients did not have HAV antibody before transfusion and none of them acquired the antibody after their illness. This was said to be strong evidence that their hepatitis was not caused by HAV. The authors also relied on incubation periods (the common ground of distinction between 'infectious' and 'serum' hepatitis, as discussed in the last chapter) and the lack of intra-familial transmission, in support of their conclusions. As noted in the previous chapter at paragraph 14.66, this work provided a basis for proof of Prince's hypothesis.<sup>10</sup>

**15.13** Further research was reported in an article in *The Lancet* of 1 November 1975.<sup>11</sup> Eight of the cases reported by Feinstone and his colleagues in April of that year were subsequently included in a prospective study of post-transfusion hepatitis by Dr Alter and colleagues (including Feinstone). For the purposes of this study a patient was considered to have post-transfusion hepatitis if, other factors being excluded,<sup>12</sup> between 14 and 180 days after transfusion the patient's alanine-aminotransferase level rose to 2.5 times the upper level of normal and if a second sample not less than a week later exceeded two times the normal level. 108 patients were followed and 12 developed hepatitis, as defined. Four of the 12 developed markers for Hepatitis B in the course of acute hepatitis and the remaining eight were classed as cases of non-B Hepatitis. Testing excluded a serological association with the Hepatitis A virus. The article concluded:

The strongest evidence that non-A, non-B hepatitis is a transfusion-related (and, by inference, virus-related) event is the fact that it appears to occur with a defined incubation period and, more important, that, like type-B hepatitis, it is considerably more common after the receipt of commercial blood than of voluntary donor blood. Thus there is increasing suspicion that there exists one or more previously unrecognised human hepatitis virus(es).<sup>13</sup>

**15.14** These three studies from 1974 and 1975 have been quoted and discussed at some length since they form the cornerstone upon which the recognition of the existence of NANB Hepatitis (subsequently Hepatitis C) is based. The expression 'non-A, non-B Hepatitis' was coined as a collective term for hepatitis in which, at that time, Hepatitis A and Hepatitis B, as well as Cytomegalovirus and Epstein-Barr virus, had been excluded.<sup>14</sup>

**15.15** Studies of post-transfusion hepatitis in the USA over this period increasingly identified the existence of an NANB Hepatitis agent and demonstrated that post-transfusion NANB Hepatitis was by no means uncommon. Depending on the source of the blood, 10% or more of transfusion patients developed ALT levels that remained elevated for weeks or even months, indicating probable non-A, non-B post-transfusion Hepatitis.

**15.16** Further work by Dr Alter and colleagues was reported in 1976.<sup>15</sup> Episodic cyclic patterns of alterations in serum transaminase levels, namely the levels of alanine transaminase (ALT) and aspartate transaminase (AST), had been identified, with raised levels alternating with near normal levels in cases of NANB Hepatitis.

<sup>10</sup> Though published first, Feinstone's work is said to have been later in date (see, for example, Zuckerman and Thomas, ed, *Viral Hepatitis: Scientific Basis and Clinical Management*,: 1993, page 470) but this must be questioned in view of the citation in the Prince paper of one paper read at the 6<sup>th</sup> symposium of the American Red Cross in May 1974. See the Preliminary Report, paragraph 6.29.

### Non-A, non-B post-transfusion hepatitis

**15.17** On 12 March 1977, Jules Dienstag and others (including Feinstone and Alter) produced a report, 'Non-A, Non-B post-transfusion hepatitis'.<sup>16</sup> This study, based on an enlarged group of 32 cardiovascular patients, provided powerful evidence that HAV was not the cause of transfusion-associated hepatitis unrelated to HBV and supported the existence of one or more NANB Hepatitis viruses.

**15.18** In July, 1977, Jay Hoofnagle and others reported the results of a rather singular study.<sup>17</sup> Stored sera from experimental studies in the 1950s, in which volunteers had been inoculated with sera from blood donors suspected of having transmitted hepatitis to transfusion recipients, were re-examined. Feinstone was again a member of the group of researchers. The discussion noted that:

Several clinical and epidemiologic features of non-A, non-B hepatitis have become clear from studies such as the present one. First, non-A, non-B hepatitis closely resembles type B hepatitis. The incubation period, the clinical symptoms and signs, and the potential for chronicity appear to be similar to type B hepatitis. Undoubtedly, what was once referred to as "serum hepatitis" included both type B and non-A, non-B hepatitis. Second, non-A, non-B hepatitis appears to be spread predominantly by the parenteral route. Most cases have been described in association with transfusion, intravenous drug use, or serum inoculation. However, as in type B hepatitis, the importance of "non-parenteral" routes of transmission (by saliva, sexual and intimate contact, biting insects) needs to be assessed. Third, non-A, non-B hepatitis appears to be associated with a chronic carrier state in chronic liver disease ... These "implicated" blood donors were, for the most part, asymptomatic, although liver function tests and liver biopsy examinations frequently showed evidence of underlying chronic hepatitis. Finally, non-A, non-B hepatitis appears to be common ... Previous studies on post-transfusion hepatitis have shown that 40% to 71% of such hepatitis is non-A, non-B. Currently all blood donations are screened for HBsAg by radioimmunoassay (or a method of similar sensitivity). Data generated from post-transfusion hepatitis studies done since the institution of such sensitive screening methods suggest that at the present time more than 90% of post-transfusion hepatitis is due to non-A non-B hepatitis.<sup>18</sup>

**15.19** They also stated that:

More and more evidence ... indicates that non-A, non-B hepatitis is due to a transmissible agent that is most likely a virus.

....

Data generated from post-transfusion hepatitis studies... suggest that... at the present time more than 90% of post-transfusion hepatitis is due to non-A, non-B hepatitis. All these features suggest the presence of one or more other human hepatitis viruses....<sup>19</sup>

<sup>16</sup> Dienstag et al, 'Non-A, Non-B Post-Transfusion Hepatitis' *The Lancet*, 1977, 1:560–62 [LIT.001.0492]

<sup>17</sup> Hoofnagle et al, 'Transmission of Non-A, Non-B Hepatitis', *Annals of Internal Medicine*, 1977; 87:14–20 [LIT.001.3657]

<sup>18</sup> Ibid [LIT.001.3657] at 3662

<sup>19</sup> Ibid [LIT.001.3657] at 3662

**15.20** This important paper strengthened the case for a viral aetiology for NANB Hepatitis, predominantly if not exclusively parenterally transmitted, with a significant association with chronic liver disease.<sup>20</sup> Hoofnagle's figures showed the combined effect of the protective measures introduced, in particular:

- The exclusion of commercial blood and prospective screening of donations for HBsAg from about 1970 in reducing Hepatitis B transmission as a component of total post-transfusion hepatitis.
- The elimination of Hepatitis A as a material component of post-transfusion hepatitis.
- Increasing confidence in the inference that non-A, non-B Hepatitis was the major component of all post transfusion hepatitis.

### Other studies

**15.21** These US studies of surgical patients and blood donors were quickly followed by a study of hepatitis in haemophilia patients, published in 1977 by Henry Lesesne and others.<sup>21</sup> Six haemophilia patients who had persistent raised serum transaminase values over a period of six months were studied. Liver biopsies were taken and half of them were found to have 'chronic active hepatitis', characterised by severe liver cell dysfunction and with a frequently poor prognosis. This was the first study in which liver biopsies were taken from haemophilia patients. Patients in the Lesesne study were given prophylactic clotting factor concentrates prior to the biopsy as liver biopsy studies on haemophilia patients were very difficult to organise due to the risk of bleeding from the biopsy site.<sup>22</sup> The authors argued that biopsy was appropriate in a range of cases because of the therapeutically important histological information obtained and their assessment of the risks associated with the procedure.

**15.22** On 22 June 1978, Joel Spero and others published 'Asymptomatic Structural Liver Disease in Hemophilia' in *The New England Journal of Medicine*.<sup>23</sup> The paper concluded:

Our results suggest that, throughout the world, a large number of asymptomatic hemophilic patients who have received numerous transfusions must have histologic liver disease. In some, it must be severe. Adequate information is not yet available to evaluate fully hemophilic patients treated only with blood products negative by radioimmunoassay for HBsAg in both donors and final product.<sup>24</sup>

**15.23** By 1978, commercial pharmaceutical companies were beginning to issue hepatitis warnings with their blood products. While a reference to 'hepatitis' was explicit, there was little specification. For example, an information leaflet provided in 1978 with Koate, a Factor VIII product produced by Cutter Biological, contained a warning that 'the presence of hepatitis virus should be assumed' and suggested that the risk of administering the

<sup>20</sup> In July 1977 Meyers et al, (including Dienstag) re-examined data previously reported in 1972 and concluded that most cases of post-transfusion hepatitis were not caused by the hepatitis A or hepatitis B virus, but by an as yet unidentified hepatitis agent: Meyers et al, 'Parenterally transmitted non-A, non-B hepatitis: an epidemic reassessed', *Annals of Internal Medicine*, 1977; 87; 57-9 [LIT.001.0183].

<sup>21</sup> Lesesne et al, 'Liver biopsy in Hemophilia A', *Annals of Internal Medicine*, 1977; 86: 703-707 [LIT.001.3712]

<sup>22</sup> It was later estimated in one study that clinically significant haemorrhage occurred in 12.5% of procedures: Aledort et al, 'A study of liver biopsies and liver disease among haemophiliacs', *Blood*, 1985; 66: 367-372 [LIT.001.0505].

<sup>23</sup> Spero et al, 'Asymptomatic Structural Liver Disease in Hemophilia', *New England Journal of Medicine*, 1978; 289: 1373-1378 [LIT.001.0177]

<sup>24</sup> Ibid [LIT.001.0177] at 0182

concentrate should be weighed against the medical consequences of withholding it, particularly for persons with few previous transfusions.<sup>25</sup> A patent for this product was granted, based on discoveries made in the Bayer (Cutter Laboratories) research laboratory during 1978–79.<sup>26</sup> The patent itself specified that therapeutically active proteins isolated from plasma might contain viruses, for example hepatitis viruses. Among commercial pharmaceutical companies, the view underpinning research by the end of the 1970s was that there was viral transmission of hepatitis by these products generally.

### Aggregated research and the emerging ALT screening debate

**15.24** In 1978, Alter and others summarised data from a number of countries concerning post-transfusion hepatitis.<sup>27</sup> Having noted the seminal work of Blumberg and others on Hepatitis B, and Prince and others on Hepatitis A, they stated:

To date, the existence of an infectious agent(s) as the cause of non-A/non-B hepatitis has not been proved since no associated particle has been observed, no growth in tissue culture has been documented, and no specific immunologic test has been developed. In the face of elevated hepatic enzymes, the diagnosis of non-A/non-B hepatitis can only be made by the serologic exclusion of other known hepatitis viruses and by the clinical exclusion of other causes of hepatocellular injury. Nonetheless, there is a rising ground-swell of evidence that substantiates the existence of at least one human hepatitis virus distinct from HAV and HBV....<sup>28</sup>

**15.25** Alter and others tabulated the findings of other researchers for the period 1975–1977, showing that in the cited reports NANB Hepatitis accounted for 63–93% of all cases of post-transfusion hepatitis.<sup>29</sup> In non-transfusion studies a wider range of NANB Hepatitis infection was noted. With no diagnostic viral blood markers, however, NANB Hepatitis remained a diagnosis of exclusion. The underlying hypothesis was that proof of elevated hepatic enzymes, particularly ALT, coupled with the exclusion of other hepatitis viruses and other causes of hepatic damage, was sufficient for a diagnosis of NANB Hepatitis. This was to divide US and UK researchers. In the USA, it was to have practical implications for clinicians.

**15.26** The scene was set for a debate on ALT screening of donors. Dr Alter and his colleagues resisted screening for a time. Their research from the early 1970s had suggested that transaminase tests had not proved to be a practical method of screening donors for hepatitis.<sup>30</sup> Richard Aach and his colleagues, who had been involved in an extensive study in the USA, the Transfusion-Transmitted Viruses (TTV) study, promoted ALT screening as a safety procedure.<sup>31</sup> The TTV study had suggested a significant association between the ALT

<sup>25</sup> See 'Examples of warnings issued with coagulation factor concentrates' [LIT.001.4488] at 4518 and 'Events concerning the safety of blood and blood products with special reference to haemophilia' [PEN.013.0220] at 0229

<sup>30</sup> Alter et al, 'Posttransfusion Hepatitis After Exclusion of Commercial and Hepatitis-B Antigen Positive Donors', *Annals of Internal Medicine*, 1972; 77: 691 – 699 [PEN.002.0811]

<sup>31</sup> The TTV study is described in Aach, RD et al, 'Serum Alanine Aminotransferase of Donors in Relation to the Risk of Non-A, Non-B Hepatitis in Recipients', *New England Journal of Medicine*, 304: 989–994. [LIT.001.0753]

levels of a donor and the likelihood of subsequent hepatitis in the recipient. Alter and his colleagues' reservations had not been overcome by the end of this period, however. The competing positions of the protagonists are discussed more fully in Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*.

### Further research

**15.27** Meantime, fundamental research continued to be reported. *The Lancet* published an article by Alter and others, 'Transmissible agent in NANB Hepatitis', on 4 March 1978.<sup>32</sup> In the study reported, chimpanzees were inoculated with serum from patients with post-transfusion NANB Hepatitis. Histological changes (changes in the microscopic anatomy of cells) in the animals ranged from mild to 'conspicuous' hepatitis and generally correlated with the degree of ALT elevation. There was said to be no evidence of clinical disease and all of the animals went on to biochemical and histological recovery. There was no serological evidence of Hepatitis A or Hepatitis B infection. Hepatitis was transmitted by serum derived from patients with chronic as well as acute hepatitis, strongly suggesting a chronic carrier state for the agent responsible for NANB Hepatitis. It was concluded that NANB Hepatitis seemed to be due to a transmissible agent which could persist and remain infectious for long periods.

**15.28** In July 1979, Dr Mones Berman and others (including Dr Alter) published 'The chronic sequelae of NANBH' in the *Annals of Internal Medicine*.<sup>33</sup> The conclusions from this study included, importantly for present purposes, a finding that although it could be clinically severe, acute NANB Hepatitis after transfusion was usually an anicteric, mildly symptomatic disease and probably went undetected in most patients not prospectively followed. It was suggested that a very large number of NANB Hepatitis cases might occur each year but that an accurate assessment of its incidence would not be possible until tests were developed that could detect specific serological markers. Among other conclusions, Berman reported that many cases of NANB Hepatitis were associated with prolonged elevation of ALT and that the predominant pathological change associated with chronic NANBH appeared to be chronic active hepatitis.

**15.29** In September 1979, Dr Athol Ware and others published a paper entitled 'Etiology of Liver Disease in Renal-Transplant Patients', also in the *Annals of Internal Medicine*.<sup>34</sup> No aetiological agent was defined in 27 of 38 patients found to have chronic hepatitis. They concluded that some if not most of these patients had chronic hepatitis secondary to infection with NANB Hepatitis. Almost without exception, the patients had received blood transfusions at the time of transplantation. The analysis added to the growing body of evidence supporting a viral aetiology for NANB Hepatitis.

### From aetiology to natural history

**15.30** At about this time the debate in the USA was moving on from discussion about whether NANB Hepatitis had a viral aetiology, which was broadly accepted, to discussion of the natural history of NANB Hepatitis infection. In July 1980, Edward Tabor and others made an unqualified comment that:

---

<sup>32</sup> Alter et al, 'Transmissible Agents in Non-A, non-B Hepatitis', *The Lancet* 4 March 1978 [LIT.001.1645]

<sup>33</sup> Berman, 'The Chronic Sequelae of Non-A, Non-B Hepatitis', *Annals of Internal Medicine*, 1979; 91:1-6 [LIT.001.0189] See the description of the study in the Preliminary Report paragraph 6.82

<sup>34</sup> Ware et al, 'Etiology of Liver Disease in Renal-Transplant Patients', *Annals of Internal Medicine*, 91: 364 [LIT.001.1052]

Non-A, non-B hepatitis is a major health problem, present in up to 89 per cent of patients with post-transfusion hepatitis and 25 per cent of hospitalized patients with sporadic hepatitis. Experimental transmission to chimpanzees of human non-A, non-B hepatitis and passage of an agent of non-A, non-B hepatitis to additional chimpanzees have demonstrated the cause to be a transmissible agent or agents.<sup>35</sup>

**15.31** The natural history of the disease continued to attract comment thereafter. On 16 December 1980, Ronald Koretz and others from the University of California, Los Angeles, published the results of research on 'The Long Term Course of Non-A, Non-B Post-transfusion Hepatitis'.<sup>36</sup> Sixty-six patients who had contracted NANB Hepatitis had been followed from 1972 for up to five years, the longest defined follow-up available at the time. Liver biopsy had revealed chronic persistent and chronic active hepatitis in all 18 patients on whom biopsy was carried out. Two developed cirrhosis. A third, not biopsied, had signs and symptoms suggesting cirrhosis. Most had, however, remained asymptomatic. The conclusion drawn was that post-transfusion NANB Hepatitis often resulted in chronic biochemical liver disease. However, if the disease progressed to liver failure it was found to do so over a number of years. It appeared to be benign in most instances. This was an influential paper because it reflected at least two to five years' follow-up of the patients in question.

**15.32** By this stage, the live issues in the USA were the relevance of elevated enzyme levels, particularly in donors, and the long-term prognosis for patients thought to be infected with NANB Hepatitis. Those disputes had not been resolved but, by the end of this period, it can safely be concluded that in the USA it had been established to a high degree of probability that NANB Hepatitis was due to a transmissible agent that was most likely to be a virus or viruses, though the agent(s) had not been identified.

### *Aetiology of NANB Hepatitis: UK and other research*

#### **Diagnosis**

**15.33** The US studies referred to are a few only within a large volume of research reports in the later 1970s and into 1980. There were almost no equivalent studies carried out in the UK. There was a significant difference of opinion on what constituted hepatitis. In the US view, 'hepatitis' was defined by raised levels of the enzyme alanine-aminotransferase by specified percentages or factors within specified periods and the absence of other causes of enzyme elevation, such as congestive heart failure and drug, alcohol or anaesthesia-induced conditions. In their 1974 report, the UK's Medical Research Council (MRC) Working Party included in their definition of 'hepatitis' a finding of enzyme elevation in association with other clinical indications of hepatitis. The requirement for additional positive indicators in the UK automatically reduced the groups of patients likely to be identified and hence yielded much lower numbers of infections attributed to post-transfusion hepatitis in UK studies than in equivalent studies in the USA.

**15.34** In clinical practice, it appears that the same view of the diagnostic features of hepatitis had a bearing on the diagnosis of post-transfusion NANB Hepatitis in the UK until 1990–91 when a test for the Hepatitis C virus (HCV) became available. Professor Peter

<sup>35</sup> Tabor, 'Chronic non-A, non-B Hepatitis Carrier State', *New England Journal of Medicine*, 1980; 303:140–143 [LIT.001.5521]

<sup>36</sup> Koretz et al, 'The Long-Term Course of Non-A, Non-B Post-transfusion Hepatitis', *Gastroenterology*, 1980; 79:893–8 [LIT.001.0201]. The paper was submitted on 18 September 1979 and accepted for publication on 16 May 1980.

Hayes, Professor of Hepatology and Honorary Consultant Gastroenterologist at the Royal Infirmary of Edinburgh, said that until there was a test for Hepatitis C, NANB Hepatitis was a very uncommon diagnosis in the UK. There were many causes of abnormal liver test results and, in his opinion, unless there was a 'trigger event', such as a blood transfusion followed by abnormal results, it was relatively unlikely that a putative viral diagnosis would have been made.<sup>37</sup>

**15.35** The UK approach was, in retrospect, too demanding. The resulting difference in diagnostic criteria applied in the UK probably led to some complacency concerning the prevalence of a possible infective agent affecting UK recipients of blood and blood products (as compared to US recipients) which lasted for over a decade. By way of example only, a comparison of the numbers thought to be infected illustrates the difference. The study by Alter and others (reported in November 1974) identified 12 of 108 patients followed (11%), as having developed hepatitis, as defined in the USA. This compared to the finding of eight out of 768 cases (1%) in which post-transfusion hepatitis had been thought to occur in the UK MRC study reported in the same year. The perception that post-transfusion hepatitis was very rare in the UK appears to have been due largely to the selection of criteria for diagnosis.

**15.36** In the UK in particular, so far as there were studies in the period to about 1981, different views developed among transfusion specialists, haemophilia specialists, virologists and public health doctors and it is appropriate to distinguish the haemophilia specialists from other groups. The response of haemophilia clinicians to the use of blood products in the light of growing knowledge is discussed in Chapters 21 and 22.

### **NANB Hepatitis and haemophilia**

**15.37** Even among haemophilia clinicians, the position was not uniform throughout Europe. In February 1975, Pier Mannucci and others published a paper on the incidence of asymptomatic liver disease in haemophilia patients treated in Milan.<sup>38</sup> Seventy-five patients with Haemophilia A and 16 with Haemophilia B were studied and classified according to age group. All had been exposed to replacement therapy with cryoprecipitate, commercial factor concentrates and, in the case of the older patients, fresh-frozen plasma. In the absence of records of the numbers of transfusions, age was selected as a 'rough but reliable parameter' to investigate any relationship between the degree of transfusion exposure and abnormality of liver function tests. Clinically, all were asymptomatic of liver disease. On physical examination five showed mild to moderate liver enlargement and two had hepatosplenomegaly (enlargement of the liver and spleen, implying possible cirrhosis). On testing, there was a high incidence of abnormal liver function test results, increasing with age. Raised ALT levels were observed in 45% of haemophilia patients, possibly caused by one or more NANB viruses. The article noted that the rate of exposure to agent(s) implicated in post-transfusion hepatitis had probably increased after the introduction of highly purified freeze-dried concentrates of Factor VIII and Factor IX manufactured by pools of plasma from many donors.

**15.38** The paper, which was published at the very outset of this period and probably written before the papers of Prince, Alter, Feinstone and others had appeared, noted that the data collected suggested that, in haemophilia patients, repeated contact with

---

<sup>37</sup> Day 78, pages 46–47

<sup>38</sup> Mannucci et al, 'Asymptomatic Liver Disease in Haemophiliacs', *Journal of Clinical Pathology*, 1975; 28:620 [SNB.008.5621]

the NANB Hepatitis agent might cause chronic liver damage that was not associated with overt illness. The discussion is instructive of the state of knowledge among Dr Mannucci's highly respected team at this time. The paper noted:

The clinical and prognostic significance of the observed abnormalities is presently unknown, and the lack of liver biopsies renders the task of clarifying them rather difficult. The great majority of the patients were completely asymptomatic and free of physical signs of liver involvement. It is possible that constant exposure to the infective agent(s) induces a general immunological tolerance conditioning an attenuated pattern of chronic hepatitis. It also seems reasonable to suggest that antibody to hepatitis B surface antigen occurring in haemophiliacs may offer protection.

However, the evidence accumulated with the investigation of asymptomatic carriers of HBsAg suggests that these humoral abnormalities are not entirely benign, since they may be associated with structural changes of the liver similar to those occurring in patients with chronic hepatitis. In haemophiliacs, an answer to these problems can be given only by a long-term prospective evaluation of any possible relationship between the observed abnormalities and the development of overt hepatic dysfunction.<sup>39</sup>

**15.39** The authors recommended regular testing. While still qualified by reservations, this was probably the first suggestion outside the USA that what became known as NANB Hepatitis occurring in haemophilia patients might be more than just a benign condition.

#### Factor concentrates

**15.40** In the UK, the MRC definition of hepatitis persisted. In August 1975, John Craske of the Public Health Laboratory, Dorset, published data on an outbreak of hepatitis following the infusion of commercial Factor VIII in the Bournemouth Haemophilia Centre.<sup>40</sup> The criteria used for diagnosis of hepatitis were jaundice or raised transaminase levels associated with compatible history and clinical signs of infection. With this publication, NANB Hepatitis had been recognised and reported by a UK haemophilia centre. The references cited did not include the earlier US publications already mentioned. As in the 1974 MRC study, the additional diagnostic criteria differentiated the approach adopted from that generally followed in the USA.

**15.41** Work by Prince and Feinstone, as well as Dr Craske's report from Bournemouth, were among the references cited in a draft protocol dated September 1975 for a prospective study of hepatitis in haemophilia associated with the use of factor concentrates in England and Wales.<sup>41</sup> The reasons for the preparation of the protocol are not clear but, at planning meetings held in 1975 for the World Health Organization (WHO) conference on Economic Aspects of Viral Hepatitis, member states who had sent representatives to the WHO conference in Copenhagen were invited to design 'study protocols' on a limited number of diseases, to carry out pilot studies which would be used to inform regional governments and to invite them to apply and adapt the methodology developed.<sup>42</sup> The UK protocol provides an insight into the views held in the UK at the time. It acknowledged

<sup>39</sup> Ibid [SNB.008.5621] at 5623

<sup>40</sup> Craske et al, 'An outbreak of hepatitis associated with intravenous injection of Factor VIII concentrate', *The Lancet*, 2 August 1975; 221–223 [LIT.001.0360]

<sup>41</sup> Study Protocol [SNB.001.6929]

<sup>42</sup> Report of a WHO Meeting on Economic Aspects of Viral Hepatitis – Copenhagen, 9–11 November 1976 [DHF.003.0283]

that the current assays had been of limited efficiency in excluding HBsAg positive donors and said:

This failure to prevent post transfusion hepatitis may be explained by the following hypotheses:

- (a) That current methods of detecting HBsAg are still not sensitive enough.
- (b) That other known viral agents are responsible, e.g., hepatitis 'A', [Epstein-Barr] virus, cytomegalo virus.
- (c) That other, as yet unknown viruses, cause a significant amount of post transfusion hepatitis which is supported by the recent work of Feinstone et al.<sup>43</sup>

**15.42** Against the background of emerging data, the study proposed to address the question:

“Does the administration of factor VIII concentrates to haemophiliacs on regular replacement therapy significantly increase the incidence of transfusion hepatitis?”<sup>44</sup>

**15.43** The proposed study also aimed to identify any difference in ‘attack rates’ as between commercial and NHS products; the value of the HBsAg positive test; further information on unknown viruses or agents; and the role of radioimmunoassay (RIA) testing for HBsAg of Factor VIII concentrates in the prevention of post-transfusion Hepatitis B. A pilot study was proposed, with the results to be provided at a meeting in Glasgow with a view to enlisting all of the UK Haemophilia Centres in the study. Had the study been carried fully into effect, it would have been a major exercise along the lines of the US investigations initiated in 1974. It was not, however, fully implemented in the UK.

### False trails

**15.44** UK experts were not alone in finding difficulties with the identification of NANB Hepatitis. At this stage, eminent researchers worldwide continued to develop hypotheses to explain NANB Hepatitis, which were later disproved. In October 1978, Ryoichi Shirachi and others published a paper entitled ‘Hepatitis “C” antigen in non-A, non-B post-transfusion hepatitis’.<sup>45</sup> They claimed to have found evidence for a new hepatitis-specific antigen in sera obtained from patients with post-transfusion NANB Hepatitis. They proposed the designation ‘hepatitis C (HC) antigen’. It was to prove to be among a number of false trails.<sup>46</sup>

**15.45** The work of the UK Haemophilia Centre Directors Hepatitis Working Party was an example of another. The Working Party met in Glasgow on 30 September 1980.<sup>47</sup> Dr Craske presented the Working Party’s report for 1979 which set out the results of surveillance for 1978 and 1979.<sup>48</sup> The report noted that the prevalence of hepatitis was about the same level as that observed in 1976–77. There had been an increase in the

<sup>43</sup> Study Protocol [SNB.001.6929]

<sup>44</sup> Ibid [SNB.001.6929]

<sup>45</sup> Shirachi et al, ‘Hepatitis “C” antigen in non-A, non-B post-transfusion hepatitis’, *The Lancet*, 21 October 1978 [LIT.001.0383]

<sup>46</sup> The overall consensus at the end of 1978 is summarised in the Preliminary Report at paragraph 6.74

<sup>47</sup> See Minutes of the Eleventh Meeting of UK Haemophilia Centre Directors Held in Glasgow, 30 September 1980 [SNB.001.7296] and the Preliminary Report para 6.99. Substantially the same material was repeated by Dr Craske at an International Symposium held on 1 and 2 October 1980 at the Royal College of Physicians, Glasgow, on ‘Unsolved Problems in Haemophilia’ [DHF.003.0649]. See also: Preliminary Report para 6.100

<sup>48</sup> Dr Craske’s report [LOT.003.5665]

proportion of cases of NANB Hepatitis reported in patients with mild disease receiving concentrates for the first time to cover operations. It was suggested that the observed increase in mildly affected haemophilia patients contracting hepatitis was probably due to the fact that most severely affected patients had already been exposed to viruses present in all brands of concentrates and were therefore immune to re-infection, while patients with mild disease had not been so exposed.

### Further haemophilia and factor concentrate research

**15.46** The natural history of NANB Hepatitis was not understood: as is now known, exposure to HCV does not confer immunity. It was concluded at the time, however, that transaminitis (elevated liver enzyme levels in the blood) was unrelated to current Factor VIII therapy and the level of anti-HBs antibody and was unrelated to a previous history of overt hepatitis. The report stated:

These results suggest that if transaminitis is related to viral hepatitis, the patients who become carriers and develop chronic liver disease will only contract mild or symptomless acute hepatitis, and the most overtly jaundiced patients will fully recover. This is supported by our observations of hepatitis B infections in haemophiliacs.<sup>49</sup>

**15.47** There were other views. As already noted in Chapter 13, *Knowledge of Viral Hepatitis Now*, paragraph 13.45, in 1978 Dr David Triger and colleagues, of Hallamshire Hospital, Sheffield, published the results of liver biopsies carried out on haemophilia patients with persistent abnormal liver function test results.<sup>50</sup> These provided a comparison with the work of Lesesne (paragraph 15.21, above). They considered it reasonable to conclude from their findings that a large proportion of haemophilia patients receiving treatment with Factor VIII had important chronic liver disease and that NANB Hepatitis may well have been an important factor, supported by observations in half of the cohort of patients studied. One patient had chronic lobular hepatitis and one micronodular cirrhosis. As indicated earlier, this work does not appear to have had wide immediate impact for the reasons set out in Chapter 13, *Knowledge of Viral Hepatitis Now*, paragraphs 13.43–13.44.

**15.48** In Europe and the USA, however, commercial companies' research had moved ahead and reflected the view that transmission of viral hepatitis by blood products, which was otherwise implicitly assumed, could be avoided by changes to manufacturing processes. A prominent example was illustrated in the work of Norbert Heimburger and a group of employees of the German pharmaceutical company Behringwerke, who in 1980 wrote a paper entitled 'Factor VIII concentrate – now free from hepatitis risk: progress in the treatment of haemophilia'.<sup>51</sup> Behringwerke had produced a heat-treated factor concentrate which they claimed did not transmit hepatitis. The product was called Factor VIII HS (ie 'hepatitis safe') and had been heated in solution to 60°C for 10 hours. It had been tested first on chimpanzees and then on 12 patients. Both groups had been monitored for a period of six–12 months and there had been no evidence of hepatitis infection. This was claimed to be the first heat-treated concentrate produced and reflected the commercial

<sup>50</sup> Preston et al, 'Percutaneous Liver Biopsy and Chronic Liver Disease in Haemophiliacs', *The Lancet*, 19 September 1978; 592–594 [LIT.001.0387]. Details are given in Preliminary Report paragraph 6.71. Professor Thomas identified this as Dr Triger's work: Day 52, page 129.

<sup>51</sup> Heimburger et al, 'Factor VIII concentrate – now free from hepatitis risk: progress in the treatment of haemophilia', *Die Gelben Hefte*, (trans. *The Golden Notebook*), 4:165–174 [SGF.001.1761]

appreciation of transmission risk and of the need to deal with it. This topic is discussed more fully in Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*.

**15.49** In November 1980, Dr Craske, in a report to the Department of Health, 'Studies on the epidemiology and chronic sequelae of FVIII and IX associated hepatitis in the UK, Appendix II: Chronic Liver disease in Haemophiliacs', stated that, despite multiple transfusions and large numbers of grossly abnormal liver function tests, very few patients showed any evidence of chronic liver disease.<sup>52</sup>

**15.50** Subsequently, on 19 March 1983, the *British Medical Journal (BMJ)* published a report on behalf of the UK Haemophilia Reference Centre Directors on the treatment of haemophilia and related disorders in the UK between 1976 and 1980.<sup>53</sup> The paper tabulated the numbers and percentages of patients treated who developed acute hepatitis. The diagnosis was based on clinical and laboratory findings and did not include patients with a known previous history of persistent abnormalities in liver function tests. Furthermore, the term 'acute hepatitis' was not defined in the report and it is likely to have missed many asymptomatic cases of NANB Hepatitis with low elevation of ALT. In the years 1976–80 the incidence in patients with Haemophilia A varied between 1.7% and 3.5% of those treated in any year and was very little different from that seen in the period 1969–74. However, with the first use of US commercial Factor VIII concentrates on a wide scale in haemophilia centres in the UK, the overall incidence of diagnosed hepatitis in patients with Haemophilia A rose from 2.3% to 5.2% in 1974 and then declined to 3.1% in 1976, remaining at about that level thereafter. Although the incidence of overt hepatitis had increased, the level of infection in the UK remained below levels in the USA. The report included the following statement:

In view of the widespread concern about the transmission of hepatitis viruses by giving blood products it is interesting to note that only two deaths were attributed to hepatitis during the five year period. There have been several reports recently of persistently abnormal liver function values and abnormal histological findings in liver tissue from haemophiliacs treated with blood products. Most of these patients are asymptomatic but it remains to be seen how many will develop severe chronic liver disease with the passage of time.<sup>54</sup>

**15.51** In 1981, a paper by Dr May Bamber and others, 'Short incubation NANB transmitted by Factor VIII concentrates in patients with congenital coagulation disorders', was published in the journal *Gut*.<sup>55</sup> The patients studied had received infusions of cryoprecipitate and commercial and NHS Factor VIII concentrate. This paper was produced by the leading UK liver unit at the Royal Free Hospital, London, in conjunction with the Royal Free Hospital Haemophilia Unit. Professor Sherlock and Professor Thomas were involved. It described 10 cases of NANB Hepatitis occurring after infusion of Factor VIII concentrates and was mainly concerned with the acute clinical course of the disease. In one group of five cases there was evidence of a direct link to a specific single infusion. In the others the patient's

<sup>54</sup> Rizza et al, 'Treatment of haemophilia and related disorders in Britain and Northern Ireland during 1976-80: report on behalf of the directors of haemophilia centres in the United Kingdom', *British Medical Journal*, 286:929–933 [LIT.001.0234] at 0238

<sup>55</sup> Bamber et al, 'Short incubation NANB transmitted by Factor VIII concentrates in patients with congenital coagulation disorders', *Gut*, 1981; 22: 854–859 [LIT.001.0483].

history of therapy confused the position. In another group of five cases the disease was asymptomatic and anicteric but in five it was more severe. None of the patients recovered within six months. The paper concluded that the failure of these patients to recover within the period of study (six–45 months) suggested that NANB Hepatitis was an important cause of liver disease in patients with coagulation disorders. The paper dealt with the histology (appearance under the microscope) of the liver in these patients. The clinical course was not dissimilar to the other clinical descriptions around that time and became much quoted. The paper stated:

Follow-up, both clinical and histological, will be needed to establish the natural history of this disease.<sup>56</sup>

**15.52** The paper also stated that there was evidence for more than one type of short incubation NANB Hepatitis virus, 'only one of which has a high rate of induction of chronic liver disease'. This view was wrong but was entertained by others at the time. The findings were affirmation of the work done at Sheffield, which had previously been controversial.<sup>57</sup> The Bamber paper, published in 1981, marked the beginning of a significant change in expert opinion. US research published in 1982 pointed in the same direction.<sup>58</sup>

**15.53** On 4 July 1981, an editorial in the *BMJ* discussed the risk to haemophilia patients. It described post-transfusion hepatitis as the major complication of the modern treatment of haemophilia and stated:

The diagnosis is usually inferred from abnormalities in the results of hepatic biochemical tests rather than from clinical evidence.<sup>59</sup>

**15.54** It referred to the biopsy-based research by Eric Preston and others at Sheffield, reported in 1978, (paragraph 15.47, above) as indicating that changes in liver architecture had occurred in haemophilia patients which were consistent with previous viral assault, including chronic persistent and chronic active hepatitis and cirrhosis. The editorial narrated rather starkly that, in some cases, early death from liver disease might prove to be the price paid by haemophilia patients for the improved quality of life afforded by the easy availability of clotting-factor concentrates. Steps taken to counter the risks were focused on three practices: the risks of collecting plasma from paid as opposed to volunteer donors; the optimum size of the donor plasma pool; and attempts at removing the several viruses of hepatitis from blood products.

**15.55** The editorial went on to identify NANB Hepatitis viruses (at least two) as the main cause of chronic liver disease in patients with haemophilia. In relation to the volunteer/paid donor issue, it referred to US evidence of a material reduction in risk when a hospital changed from commercial to volunteer blood. In relation to the attempts at removing viruses of hepatitis from blood products, there was again relevant evidence. The final paragraph stated:

[I]n the absence of specific markers for non-A, non-B hepatitis, overall protection against hepatitis appears remote. A more likely possibility is that hepatitis-free blood products will become available ....<sup>60</sup>

<sup>56</sup> Ibid [LIT.001.0483] at 0489

<sup>58</sup> Koretz et al, 'Non-A, non-B post-transfusion hepatitis: disaster after decades', *Hepatology*, 1982; 2:687 [LIT.001.3738]; Professor Thomas' Report [PEN.017.1079] at 1080

<sup>59</sup> 'Post-transfusion hepatitis', *British Medical Journal*, 4 July 1981 [LIT.001.0227]

<sup>60</sup> Ibid [LIT.001.0227]

**15.56** The editorial referred to three recent reports dealing with heat-inactivation, chemical treatment with  $\beta$ -propiolactone and wet-heat treatment processes as more likely to achieve the removal of viral contamination.<sup>61</sup> By this stage it was being recognised that where NANB Hepatitis was established in blood coagulation patients it carried a risk of chronic liver disease and the biopsy findings reported by Preston and colleagues were being noted.

### Post-transfusion NANB Hepatitis

**15.57** In contrast to the work published in relation to hepatitis in haemophilia patients, work on post-transfusion hepatitis between 1975 and 1981 was less homogeneous and tended to arise from specific issues. At government level, a plethora of committees and working parties was established by the Department for Health and Social Security (DHSS), the MRC and the Haemophilia Centre Directors. NANB Hepatitis and its relevance to transfusion and haemophilia therapy were discussed, but no studies of post-transfusion hepatitis were established in the UK comparable to the several carried out in the USA.

**15.58** There were some peripheral developments in regulation. In the context of public health, 'infective hepatitis' had been listed as a notifiable disease from 1968.<sup>62</sup> In February 1976, 'viral hepatitis' was prescribed as an industrial disease for the purposes of the Social Security Act 1975. Employees infected in the course of work became entitled to certain forms of benefit, including injury benefit. The circular announcing the development stated:

The prescription includes the two commoner forms of viral hepatitis known as hepatitis A (infectious hepatitis) and hepatitis B (serum hepatitis; Australia antigen positive hepatitis).<sup>63</sup>

**15.59** NANB Hepatitis, in absolute terms or relative to Hepatitis A and B, was not acknowledged.

**15.60** Precisely because the signs and symptoms were so mild and the blood tests lacking the results of a comprehensive study, the general opinion in Scotland (outwith haemophilia care) at this stage was that NANB Hepatitis was a rare and relatively unimportant disease. In a letter written on 26 March 1975 to John Wallace, Regional Director of the Glasgow and West of Scotland Blood Transfusion Service, Major General Jeffrey, National Medical Director, SNBTS, commented that in the light of current knowledge a few cases of post-transfusion hepatitis were 'bound to arise'. The letter was copied to Dr McIntyre at SHHD. The General referred to US literature which was clearly known but which, at that stage, had not impressed him as giving rise to significant concern.<sup>64</sup>

**15.61** In 1979, Dr Ajay Chaudhuri and others published in the *Communicable Diseases Scotland Weekly Report* a paper based on haemophilia and non-haemophilia patients, 'Viral Hepatitis in Glasgow, 1976 – 1977'. It found that:

During the two-year period from January, 1976, to December, 1977, 164 patients with viral hepatitis were admitted to the Infectious Diseases Units at Ruchill and Belvidere Hospitals, Glasgow. Of these, 52 (32 per cent) patients had hepatitis B as they were found to be HBsAg positive. In 112 patients who

---

<sup>61</sup> The article refers to them as 'specific processing by chemicals, ultraviolet light, or heating'.

<sup>62</sup> See Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraph 14.13.

<sup>63</sup> Scottish Home and Health Department circular [SGF.001.2818]

<sup>64</sup> General Jeffrey's letter [SGF.001.2780]

were HBsAg negative, a diagnosis of non-B hepatitis was made; however, in a majority of these patients, epidemiological findings and clinical course suggested a diagnosis of hepatitis A.<sup>65</sup>

**15.62** Retrospective testing for antibody to HAV showed that two thirds of the non-B cases were attributable to Hepatitis A. Under the heading 'Non-A – non-B Hepatitis' the authors stated:

In four patients with non-B hepatitis, hepatitis developed within 2-6 months of transfusion of blood products. Three male haemophiliacs and a female patient with Christmas disease had received numerous transfusions of factor VIII and cryoprecipitate. These four patients and also two drug addicts with hepatitis had no evidence of hepatitis B infection, nor of hepatitis A infection nor of infection with cytomegalovirus, nor EB virus. At present they are classified as cases of non-A -- non-B hepatitis. Evidence from other countries suggests that a virus (or viruses) may be associated with this type of hepatitis and that a carrier state is possible. With laboratory tests now permitting definitive diagnosis of hepatitis A virus infection, as well as hepatitis B, in 1979 it should be possible to determine the prevalence of non-A – non-B hepatitis in the general population in West Scotland.<sup>66</sup>

**15.63** The paper reflected experience in an infectious diseases unit: only a small proportion of NANB Hepatitis patients had overt clinical symptoms of disease sufficiently severe to lead to referral to the infectious diseases hospital.

**15.64** In the international context, there was some recognition of the risk of hepatitis other than A or B at a WHO meeting on the Economic Aspects of Viral Hepatitis in Copenhagen, held between 9 and 11 November 1976. Viral hepatitis was defined as acute inflammation of the liver caused by HAV, HBV, 'or by other hepatitis viruses'. It was reported:

Progress in the specific diagnosis of viral hepatitis has revealed a new type of hepatitis that is unrelated to hepatitis A or B virus. It appears to be now the most common form of hepatitis occurring after blood transfusion in some areas. There are no laboratory tests available as yet for identifying this agent or agents.<sup>67</sup>

**15.65** This report indicated an increasing international awareness of a problem but little direction towards a solution.

**15.66** On 8 January 1979, a doctor (name redacted) of the School of Pathology, the Middlesex Hospital, wrote to the DHSS advising that the stimulus for re-convening the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen was to 'upgrade' the 'viral safety' of UK Factor VIII concentrates. The letter also stated:

I have a note to write to you about non-A, non-B hepatitis.

If one or more of these viruses is responsible for the abnormal livers which are evidently common among haemophiliacs then chronic liver disease due to

<sup>65</sup> Chaudhuri et al, 'Viral Hepatitis in Glasgow', 1976-1977', *Communicable Diseases Scotland Weekly Report*, 1978; 78(8) [PEN.002.0511]

<sup>66</sup> Ibid [PEN.002.0511] at 0513

<sup>67</sup> Report of a WHO Meeting on Economic Aspects of Viral Hepatitis – Copenhagen, 9–11 November 1976 [DHF.003.0283] at 0285

these viruses might also be found among other transfused individuals. What I was asking Y [name redacted]<sup>68</sup> was whether she could question her patients with chronic liver disease about past transfusions. There could be merits in starting with an actual clinical problem and working backwards.

If we are going to consider non-A, non-B seriously in the Advisory Group it would be logical to co-opt Z [name redacted]<sup>69</sup> of the PHLS, Manchester. He is making a continuing study of the problem of hepatitis in haemophiliacs.<sup>70</sup>

**15.67** The identity of the author of this letter is not disclosed but may have been Dr David Dane. If it was Dr Dane (a member of the original and reconvened Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen, an eminent pathologist and commentator),<sup>71</sup> it is unlikely that he was at this stage unaware of the US literature on NANB Hepatitis among transfused patients: the work of Prince and others in and after 1974 had reported on cardiac surgery patients. That they were at risk was known from the earliest days of NANB Hepatitis. However, it appears at least to have been an opening for study of the wider problem and progress followed.

#### Medical Research Council ad hoc meeting

**15.68** On 7 February 1979, a letter was sent out by a Senior Medical Officer of the MRC thanking individuals for agreeing to attend an ad hoc meeting to be held on 12 February 1979.<sup>72</sup> The meeting was to discuss growing anxiety about the threat of NANB Hepatitis to patients and laboratory staff and the need for research to characterise the agent causing the disease and to develop a test for the organism or its marker. The letter noted that a commercial concentrate had been found to transmit NANB Hepatitis to chimpanzees and, as a result, it had not been given a licence. It quoted advice received from the Institute of Allergy and Infectious Diseases, Bethesda, Maryland:

1) The non-A, non-B agent has not yet been purified from the livers of infected individuals or animals, or from the stool. Most recently it has been reported that the agent has been transmitted to chimpanzees. There is a preliminary report that the non-A, non-B agent has been visualized by electron microscopy in the livers of infected chimpanzees. This, however, needs further documentation. While the chimpanzee is a clumsy experimental animal, this will provide new opportunities for characterising the agent. As with all the hepatitis viruses, non-A, non-B has yet to be cultivated.

2) Your second question concerns antigenic markers and diagnostic tests. These are not yet available, because of the negative results listed in the paragraph above.<sup>73</sup>

**15.69** On 12 February 1979, the MRC hosted the proposed ad hoc meeting.<sup>74</sup> The meeting was attended by eminent experts including Professors Sherlock and Zuckerman, Sir William Maycock, Dr Craske and Dr Philip Mortimer. Professor Zuckerman had led

<sup>68</sup> Y was probably Dame Sheila Sherlock.

<sup>69</sup> Z was probably Dr Craske, who by this time had moved to Manchester.

<sup>70</sup> Letter of 8 January 1979 [DHF.003.0324]

<sup>71</sup> See Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraph 14.28

<sup>72</sup> Letter of 2nd February 1979 [DHF.003.0323]

the previous MRC study published in 1974. The discussion of parenterally transmitted NANB Hepatitis provides an insight into the state of knowledge at the time. There was a view, advanced by Dr Thomas Cleghorn and supported by Professor Sherlock, that post-transfusion hepatitis (PTH) 'must now be rare and that it would be difficult to find many cases.' The ground for the observation appears to have been that, despite the transfusion of 1.5 million units of blood in the previous year, 'very little had been heard of non-A, non-B PTH'. Professor Zuckerman countered by observing that much NANB Hepatitis might be anicteric and that the risk of progression to chronic liver disease remained, however mild the initial infection. Professor Sherlock was concerned about the risks of transmission associated with imported commercial products but Dr Craske reported that his group had also found NANB Hepatitis associated with blood products of NHS origin. The conclusion of this discussion was reported as follows:

The Chairman [Professor Mollison] then asked what exactly constituted a case of non-A non-B hepatitis. It was agreed that HBV infection must be excluded by sensitive tests for HBsAg and anti-HBc, and that recent infection with HAV, EB virus and cytomegalovirus must also be excluded. Blood enzyme tests, particularly SGPT, could be a useful pointer to non-A non-B infection, but there was an urgent need for specific markers of non-A non-B viruses. The Chairman suggested, and Professors Sherlock and Zuckerman agreed, that until there were such markers, a survey of PTH – as suggested by Sir William Maycock – was not warranted.<sup>75</sup>

**15.70** More limited research and arrangements to store sera for later examination were then discussed. The decision not to initiate a survey of post-transfusion hepatitis was to lead to the serious long-term consequences of postponing investigation of the prevalence of post-transfusion NANB Hepatitis in the UK. At that time there was no reasonable prospect of developing a specific marker for NANB Hepatitis in early course. Rather, diagnosis depended on exclusion of other causes of hepatitis in the patient and the participants clearly understood that, as the minute shows. The committee's remit was related to the allocation of research funds and that may explain the decision taken that, until specific markers for non-A, non-B viruses had been developed, a survey of post-transfusion hepatitis was not warranted. The discussion demonstrated, however, that among this eminent group the risk of transfusion-transmitted NANB Hepatitis as understood in the USA was not accepted, though a paper by Dr Alter and colleagues on the 'Transmissible Agent in Non-A, Non-B Hepatitis' was included in the literature before the committee.<sup>76</sup> As events were soon to show, it was the view of Dr Brian McClelland<sup>77</sup> that a well-structured study could be devised but the decision at the 1979 meeting hardened views against that course.<sup>78</sup>

**15.71** The Regional Transfusion Directors held their 176th meeting on 3 October 1979.<sup>79</sup> It was reported that the Advisory Group on the Testing for the Presence of Hepatitis B Surface Antigen and its Antibody was concerned about the incidence of post-transfusion

<sup>79</sup> Meeting minutes [DHF.002.8109]

jaundice. The group was particularly anxious to receive from the regions details of patients suffering from NANB Hepatitis and stated that it would appreciate receiving samples of serum from these patients. Directors were reminded of the need to report all cases of post-transfusion hepatitis. It is noteworthy that, as far as the Transfusion Directors were concerned, post-transfusion hepatitis was still being discussed in terms of jaundice at this date.

**15.72** At about this time, other evidence of severe liver disease associated with NANB Hepatitis was being reported. In 1979 Sten Iwarson and others reported two cases in which there was a well-documented progression to serious liver disease, in a paper entitled 'Progression of hepatitis non-A, non-B to chronic active hepatitis'.<sup>80</sup>

### Working Party on Post-Transfusion Hepatitis

**15.73** The ad hoc meeting in February 1979 led to the MRC setting up a Working Party on Post-Transfusion Hepatitis which met for the first time on 14 February 1980.<sup>81</sup> The Working Party was chaired by Dr Harold Gunson<sup>82</sup> and its members included Professors Sherlock and Zuckerman, Dr WJ Jenkins,<sup>83</sup> Dr McClelland, Drs Craske, Polakoff and Tobin of the Public Health Laboratory Service (PHLS) and Dr Diana Walford of the DHSS.<sup>84</sup> The function of the Working Party was agreed to be:

[T]o promote research to assess the nature and size of the problem of PTH in the UK, with particular reference to changes in transfusion practice .... Studies should include (1) an assessment of any further need for research into Hepatitis B... (2) investigations to assess the incidence of non-A, non-B hepatitis in the UK, particularly with the risk of introducing the infection by blood transfusions, and (3) the position of research to characterise the agent(s) associated with this form of hepatitis, and to derive diagnostic tests.<sup>85</sup>

**15.74** In respect of the incidence of post-transfusion hepatitis in the UK, it was noted that '[n]o cases of NANB Hepatitis related to whole blood transfusions had yet been reported despite enquiry of hospitals in London where open heart surgery was carried out'. Dr McClelland proposed a multi-centre study, which might be sponsored by the MRC, into the association of NANB Hepatitis with blood transfusion. It was minuted that this proposal was deferred.

**15.75** Deferral of Dr McClelland's proposal in effect repeated the decision taken at the ad hoc meeting of the MRC. However, Dr McClelland proceeded to propose a multi-centre prospective study at the next meeting of the Working Party, held on 25 June 1981.<sup>86</sup> In his evidence to the Inquiry Dr McClelland stated that, in doing so, he clearly behaved as though there had been no agreement to defer the study.<sup>87</sup> Whatever the accuracy of the minute, Dr McClelland made no progress.

<sup>87</sup> Day 63, page 63. See Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*.

**15.76** The second meeting of the MRC Working Party, on 25 June 1981, proved to be the last.<sup>88</sup> Professor Zuckerman gave a summary of the research work that had been carried out over the past two years on post-transfusion hepatitis among other forms of the disease. He and Dr Howard Thomas spoke of difficulties that had been encountered in devising serological and radioimmunoassay techniques for identifying NANB viruses. Other aspects of the meeting, related to the question of a prospective study of post-transfusion hepatitis and particularly in relation to potential surrogate screening, are dealt with in paragraphs 27.78–27.83 of Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*. However, in brief, the demise of the Working Party, implying the exhaustion of its wide remit, put an end to Dr McClelland's proposal for the time being.

**15.77** Dr McClelland was not alone in his concern that there should be an investigation. The Advisory Group on the Testing for the Presence of Hepatitis B Surface Antigen and its Antibody presented its third report in 1981.<sup>89</sup> The group included Professor Sherlock, Professor Zuckerman, Dr Craske, Professor John Cash and Dr Edward Follett among others. In relation to NANB Hepatitis, it stated:

Non-A, non-B hepatitis viruses are a common cause of PTH in the United States and are thought to have been responsible for cases of PTH in the UK. Hepatitis due to these viruses is common among haemophiliacs and follows the administration of imported, and occasionally of British Factor VIII and Factor IX. There is evidence for the occurrence of sporadic cases of non-A, non-B hepatitis in the general adult population and in association with cryoprecipitate therapy in the UK.

There are at the present time no screening tests for detecting non-A, non-B hepatitis viruses in blood donation.

We recommend that research is undertaken in the UK to determine the extent and severity of PTH due to non-A, non-B hepatitis viruses. Unless this is done we will not have the knowledge on which to base any possible future recommendations about screening blood donations for these viruses.<sup>90</sup>

**15.78** Reporting of relevant evidence was encouraged. Separately, in relation to liver function tests, the report stated:

Several categories of people are found to have raised blood transaminase levels which are not associated with viral hepatitis. Some 3% of new donors may be excluded if the criteria of one raised transaminase level is applied. In addition to the need for confirmatory transaminase testing the worry and inconvenience caused to donors would be unlikely to be compensated for by any clinical benefit. Therefore we advise against these tests in screening blood donors at the present time but the subject should be kept under review.<sup>91</sup>

### ***Knowledge of NANB Hepatitis: Summary as at 1981***

**15.79** The relevance of elevated enzyme levels was still a live issue in the USA at this stage. The final paragraph of advice quoted above was not altogether out of line with

<sup>89</sup> Third Report of the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen and its Antibody [DHF.003.0037]

<sup>90</sup> Ibid [DHF.003.0037] at 0045–46

<sup>91</sup> Ibid [DHF.003.0037] at 0046

that position. However, along with the reports from other meetings in and after 1979 discussed above, it reflects some of the confusion prevalent at the time. It was correctly acknowledged that several categories of people can have raised transaminases not associated with viral hepatitis. Alcohol and obesity may play a part, for example, but unless all cases of elevated liver enzymes were associated with those categories there had to be a cohort whose elevated enzyme levels might be associated with NANB Hepatitis. The recommendation that there should be research was not followed up, however.

**15.80** There were clearly differences in attitude to the possible occurrence of NANB Hepatitis infection. By 1980–81, haemophilia doctors saw NANB Hepatitis as a very frequent infection in haemophilia patients but one usually mild in both course and outcome. Haemophilia clinicians had close and continuing contact with their patients and haemophilia care involved frequent testing of patients' blood. Other health professionals saw NANB Hepatitis following blood transfusion as rare and relatively unimportant. That there were these differences was due at least in part to the fact that there had been no appropriate studies of post-transfusion hepatitis in the UK for a decade.

**15.81** Things were, however, beginning to change. By the start of 1981, the UK Advisory Committee on Dangerous Pathogens had been established.<sup>92</sup> In Scotland also, there was some practical progress. In March 1981, Professor Cash, Medical Director, SNBTS, prepared a brief report for discussion by the SNBTS Directors entitled 'Hepatitis and the Transfusion Service'.<sup>93</sup> He proposed that the West of Scotland Centre should be nominated as a Hepatitis Reference Centre and that it should establish and issue the necessary protocols and reagents for effective quality assurance. Provision was made for supervision, procedures and reporting. The report set out specific proposals for optimal collection of plasma, screening for anti-HBs and standards for testing. Professor Cash proposed to ask Professor Zuckerman for advice on the safety of current vaccination preparations. There were specific proposals for infants born of mothers who were chronic HBsAg carriers.

**15.82** The series of US studies referred to above show that, while there was no proof to the standard of the mathematical certainty of a viral aetiology, the clear balance of opinion in the USA was that a viral aetiology for NANB Hepatitis had been established, probably by the end of 1978 and clearly by 1980.<sup>94</sup>

**15.83** The position in the UK is less easy to define. Virologists and public health experts appear to have implicitly accepted in their publications that there was a viral aetiology. Dr Craske's reports adopted that position in August 1978 and it was implicit in his November 1978 paper. The same position can be inferred from the Middlesex Hospital and MRC letters of January and February 1979. The view was explicit in the reason for setting up the Hepatitis Advisory Group in September 1980. The *BMJ* editorial of 4 July 1981 explicitly noted two or more NANB Hepatitis viruses as the main cause of chronic liver disease in haemophilia patients.

**15.84** So far as haemophilia clinicians were concerned, while some may have been less committed to a viral aetiology, most commentators were aligned with Dr Craske. The papers from Bamber, the Haemophilia Unit at the Royal Free Hospital and from Norkrans and colleagues and the *BMJ* editorial all subscribed to a viral aetiology. Dr Craske's third and final report of the Oxford project of the United Kingdom Haemophilia Centre

<sup>92</sup> Minutes of Advisory Group on Hepatitis Meeting, 5 December 1980 [DHF.001.0620]

<sup>93</sup> Hepatitis and The Transfusion Service – Status Report and Proposals for Discussion by SNBTS Directors [SNB.003.5831]

<sup>94</sup> Paragraph 15.30: Tabor and colleagues.

Doctors Organisation (UKHCDO), for 1980–81, as presented to the UKHCDO Hepatitis Working Party in September 1980, referred explicitly to NANB viruses. It was not strongly questioned. The minutes of the Glasgow meeting of the Working Party appear less positive. 'Transaminitis' was not unequivocally accepted to be associated with viral hepatitis. The report as published in 1981 still treated the question of the significance of chronic hepatitis in patients with chronically elevated transaminases as unanswered.

**15.85** Most UK blood transfusion directors still maintained that NANB Hepatitis was a rare condition, seldom seen because they were looking for the wrong thing: acute jaundice. They did, however, acknowledge that a viral aetiology was very probable.

**15.86** The 6th edition of *Diseases of the Liver and Biliary System* by Professor Sheila Sherlock was published in 1981. Excerpts from the book are quoted in the Preliminary Report at paragraphs 6.110–6.114. Significant points made were:

- NANB Hepatitis was largely spread by blood and accounted for about 75% of PTH and possibly 15–20% of sporadic hepatitis; and
- Haemophilia patients receiving factor concentrates obtained from commercial sources were particularly at risk.<sup>95</sup>
- The NANB Hepatitis agent had not been 'conclusively identified' and its identity remained uncertain; and
- The clinical course of the disease progressed to a 'mild, chronic hepatitis' in about a quarter of patients but this usually improved with time although cirrhosis could develop.<sup>96</sup>

**15.87** Professor Sherlock commented that:

Non-A, non-B hepatitis often progresses to a mild chronic hepatitis. The prognosis of this is, at the moment, uncertain but probably benign.<sup>97</sup>

**15.88** Commenting on this edition, Dr McClelland said in oral evidence:

Well, all I can really say to that is that Professor Sherlock was obviously the doyenne of hepatology in the UK at the time. I would assume that in preparing the various successive editions of her textbook, she would have firstly read the literature pretty well and secondly have consulted experts internationally. So I mean this has to be considered as an authoritative view, which may not be the same as being a correct view.<sup>98</sup>

**15.89** By the end of 1981 there had been further advances. However, particularly because there was still no known reliable marker for the putative virus or viruses causing NANB Hepatitis, there was continuing controversy around the natural history of the disease. Differences among professional groups reflected the fact that, by 1981, there was still very little evidence as to the natural history of NANB Hepatitis – whether arising post-transfusion in general medical or surgical contexts or among haemophilia patients.

---

<sup>96</sup> Ibid page 258

<sup>97</sup> Ibid page 259

<sup>98</sup> Day 9, page 66

**15.90** The apparent incidence of post-transfusion NANB Hepatitis varied substantially according to the population of blood donors used and to the methods used to detect it, adding to the complexity of the issues. However, positive developments included the following:

- Discussion was beginning concerning ways of reducing post-transfusion hepatitis by using possible surrogate markers to identify blood carrying a high risk of transmitting NANB Hepatitis virus(es). (The subject of 'surrogate markers' – markers, short of a reliable serological test, that might be indicative of infection – is dealt with in Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*).
- The first attempts were made at viral inactivation in blood products and the recognition (though not satisfactory resolution) of difficulties of maintaining yield of effective Factor VIII and Factor IX activity during processing, especially with heat treatment methods (dealt with in Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*).
- There was recognition that there was already a problem, namely that the vast majority of severely affected and moderately severely affected haemophilia patients receiving replacement therapy already had been exposed to NANB Hepatitis virus(es) and that many had chronic, although, it was perceived, probably usually mild and asymptomatic, liver disease.

**15.91** At this stage, there was no understanding, or probably even perception, of the less tangible symptoms of lethargy, depression and other neurological symptoms of chronic HCV infection which have come to be understood increasingly over the last 15 years. These symptoms are discussed in Chapter 13, *Knowledge of Viral Hepatitis Now*. At the beginning of the 1980s, and for long thereafter, descriptions of patients as 'asymptomatic' referred to recognised symptoms of significant chronic liver disease, regardless of cause, as they were perceived from time to time. It is now impossible to know what proportion of individuals described as having 'asymptomatic chronic liver disease' did in fact have less tangible, but real, symptoms of disease, since no systematic inquiry was carried out.

**15.92** In the UK, studies based on biopsy findings in haemophilia patients with putative NANB Hepatitis, first published by researchers in Sheffield in 1978, were just beginning to be taken up more widely. Work at Sheffield and the Royal Free Hospital was reported at the 11th meeting of the UKHCDO on 30 September 1980.<sup>99</sup> This would make an impact as the second half of the period progressed.

### **Viral hepatitis 1982–1985**

**15.93** The most pressing issues in the period 1982–85, for those dealing with blood and blood products, were AIDS and the steps taken to tackle that disease. These are more fully discussed elsewhere in this Report.<sup>100</sup> There was increasing apprehension of a disease of epidemic proportions with high mortality. There is at least an element of artificiality in discussing events that had a direct bearing on the developing knowledge of NANB Hepatitis dissociated from the far more pressing background preoccupation with AIDS. As it became accepted that AIDS was a viral disease, the implications of viral infection

<sup>99</sup> Minutes of the Eleventh Meeting of UK Haemophilia Centre Directors Held in Glasgow on 30 September 1980 [SNB.001.7296] at 7304

<sup>100</sup> Chapters 9 and 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 1 and 2* and Chapter 12, *HIV/AIDS – Response and Clinical Practice*.

more generally, including NANB Hepatitis infection, were inevitably examined in a wider context. However, there were important developments in knowledge of NANB Hepatitis, even while the major preoccupation was with AIDS, and the following discussion seeks to identify and comment on these developments.

**15.94** In the period 1982–85, evidence from biopsy investigation became more significant in promoting an understanding of the natural history of NANB Hepatitis. A number of studies were reported between 1982 and 1985 in which liver biopsies were taken from patients with NANB Hepatitis – both haemophilia patients and those with presumed NANB Hepatitis following blood transfusion. The studies showed that some patients developed cirrhosis.<sup>101</sup> These histological findings of extracted liver samples under microscopic analysis suggested that the disease might be more serious than previously thought, despite the fact that few patients, even among those who developed cirrhosis, otherwise suffered clinical symptoms.

**15.95** Also in this period, studies in England showed that most haemophilia patients who routinely received Factor VIII and Factor IX blood products, whether manufactured by the National Health Service (NHS) or by commercial companies, were likely to develop NANB Hepatitis.<sup>102</sup>

**15.96** Early heat-treated Factor VIII concentrates were developed but were found to transmit NANB Hepatitis notwithstanding heat-treatment.<sup>103</sup> Effective heat-treatment would be developed and brought into the production processes after the end of this period.

**15.97** Throughout this period, the Hepatitis C virus had still to be identified with the result that there was no direct test for the virus or its antibody. Instead, consideration was given to testing blood donations for certain indirect, or surrogate, markers in the blood of donors (particularly elevated ALT and antibody to the Hepatitis B core antigen (anti-HBc) that studies in the USA had indicated might be so closely associated with the development of NANB Hepatitis in recipients as to be indicative of infection).

**15.98** Much of the source material for this period is set out in Chapter 7 of the Preliminary Report. Sources are not repeated here unless it is necessary for an understanding of developing knowledge on particular matters. As before, developments in the USA are noted first.

### ***NANB Hepatitis aetiology and natural history: research in the United States of America***

**15.99** In the USA, published research dealt increasingly with the natural history of NANB Hepatitis. In 1982, there were conflicting reports of biopsy results. A study by Koretz and others of presumed post-transfusion NANB Hepatitis found chronic hepatitis and/or cirrhosis in about a third of patients. There was a significant association of cirrhosis with

<sup>101</sup> The following studies, and the conclusions drawn from them at the time, are more fully discussed below: Realdi (1982), Koretz (1982), Mannucci (1982), White (1982), Stevens (1983), Hay (1985), Aledort (1985).

<sup>102</sup> Fletcher et al, 'Non-A non-B hepatitis after transfusion of factor VIII in infrequently treated patients', *British Medical Journal*, 1983; 287:1754–57 [LIT.001.0239]; Kernoff et al, 'High risk of non-A, non-B hepatitis after a first exposure to volunteer or commercial clotting factor concentrates: effects of prophylactic immune serum globulin', *British Journal of Haematology*, 1985; 60:469–479 [LIT.001.0800]

<sup>103</sup> Informally reported by Professor Mannucci at a meeting of the European Society of Haematology in Barcelona in September 1983. (See Mannucci, 'AIDS, hepatitis and hemophilia in the 1980s: memoirs from an insider', *Journal of Thrombosis and Haemostasis*, 2003; 1:2065–69 [LIT.001.1101] at 1104) and subsequently published by Colombo et al, 'Transmission of [NANB Hepatitis] by heat-treated factor VIII concentrate', *The Lancet*, 1985; 2:1–4 [LIT.001.0369]

those who had persistently abnormal ALT values.<sup>104</sup> They reported that cirrhosis developed in a clinically silent fashion and usually only after years of virus activity. In another 1982 paper, RJ Gerety and DL Aronson reported progression to chronic hepatitis characterised by widely fluctuating serum aminotransferase levels and histologically severe liver disease in a high proportion of infected individuals and referred to similar findings by Pier Mannucci.<sup>105</sup>

**15.100** In contrast to these reports, the study by Gilbert C White and others of 15 haemophilia patients with intermittently (not persistently) raised ALT, values found no suggestion of chronic liver disease.<sup>106</sup> They reported that liver biopsies showed chronic persistent hepatitis or other mild forms of liver disease including mild chronic portal inflammation. The authors concluded:

The high frequency of liver function abnormalities in patients with hemophilia coupled with biopsy evidence of chronic active hepatitis and the documentation of progression to cirrhosis have led some authors to question current policies of replacement with concentrates of factor VIII for some patients. While some patients, primarily those with moderately severe and severe enzyme elevations, will have histologic evidence of chronic active hepatitis and/or cirrhosis, the results of the present study indicate that a larger proportion of patients will have milder degrees of enzyme abnormalities and predominantly chronic persistent hepatitis or milder forms of liver disease. Thus, for many transfusion-requiring hemophiliacs, the frequent exposure to factor VIII concentrates is not accompanied by the development of the more severe forms of chronic liver disease.<sup>107</sup>

**15.101** A review by Dienstag in 1983 concluded that after transfusion with blood or blood products, as many as 40–60% of patients with acute NANB Hepatitis would have chronic elevations of serum aminotransferase activity, often in a fluctuating pattern, and histologic features of the liver consistent with chronic active hepatitis, with approximately 10–20% of chronic cases eventuating in cirrhosis.<sup>108</sup>

**15.102** Against this uncertain background, regulators were cautious. The issue of *Morbidity and Mortality Weekly Report (MMWR)*, the journal of the US Centers for Disease Control (CDC), of 7 June 1985 set out a fairly comprehensive statement of current knowledge in the USA of hepatitis viruses and diseases, with guidance on protection against viral hepatitis, including vaccination.<sup>109</sup> Reflecting only established scientific knowledge, the treatment of NANB Hepatitis was brief. The paper noted that the epidemiological characteristics of NANB Hepatitis were similar to those of Hepatitis B, occurring most commonly following blood transfusion and parenteral (injecting) drug use. Multiple episodes had been observed in the same individuals and were thought to have perhaps been due to different agents. Chronic hepatitis following acute NANB Hepatitis infection varied in frequency from 20%

<sup>109</sup> *MMWR* 7 June 1985 [LIT.001.0465]

to 70%. Experimental studies in chimpanzees had confirmed the existence of a carrier state which might be present in up to eight per cent of the population.<sup>110</sup> There were no recommendations for action, although other US comment was more forthright.

**15.103** The tentative views set out in the *MMWR* proved to be incorrect in certain respects. The conclusion that apparent multiple episodes of NANB Hepatitis in the same individuals might be due to different agents would turn out to be incorrect. Also incorrect was the speculation that a carrier state might be present in up to 8% of the general population. It is important, however, to emphasise that these were views of recognised experts and represented advanced thinking based on the data that CDC, reasonably in the circumstances, considered to be reliable.

**15.104** In 1985 Dr Alter of the NIH set out what was known, in his view, about post-transfusion hepatitis at that time.<sup>111</sup> His report provides an important point of reference on this topic. In relation to the natural history of NANB Hepatitis, he stated that the importance of the disease was not in its acute manifestations but in its chronic sequelae, the long-term abnormal conditions resulting from the disease. An 'astounding' number of cases progressed to chronic hepatitis, as judged by persistent ALT elevations. There was accumulating evidence that some cases progressed to severe chronic liver disease. At least 10% of patients who developed chronic ALT elevations following acute post-transfusion hepatitis progressed to cirrhosis. His view was that if these findings were validated, then the clinical implications of NANB Hepatitis were somewhat more serious than previously anticipated. This view was shared by some US specialists but was not universally endorsed by US haemophilia clinicians and other specialists.

**15.105** In August 1985 Louis Aledort and colleagues (from different disciplines in New York and other international centres) reported on the largest study at the time of liver biopsies and liver disease among patients with haemophilia.<sup>112</sup> Dr Aledort was one of the doyens of US haemophilia (and hence world haemophilia) specialists. The other authors represented some of the world's leading and best liver pathologists (from the USA, the UK, Belgium and Switzerland) and at least one leading US clinical liver specialist. Although this paper was published in August 1985, it is of interest that it was submitted for publication on 5 July 1983 and that parts of it were presented at a meeting towards the end of 1981, according to a note in the paper.<sup>113</sup> Liver samples and associated clinical data were collected from 155 patients from haemophilia centres in the USA and Western Europe. For 115 there were reports of liver biopsies and for the remaining 40 there were autopsy findings.

**15.106** The authors reported that in those subjects with haemophilia the incidence of cirrhosis (15%) and chronic active hepatitis (7%) was lower than previously reported. The frequency of severe liver disease (chronic active hepatitis or cirrhosis) in patients receiving large pooled concentrates was no greater than in patients treated principally with cryoprecipitate or plasma. This had not originally been predicted since patients receiving cryoprecipitate or plasma were exposed to far fewer donors per dose as compared to those receiving concentrate. The finding led the authors to conclude that there appeared

<sup>110</sup> Ibid [LIT.001.0465] at 0478

<sup>112</sup> Aledort et al, 'A study of liver biopsies and liver disease among haemophiliacs', *Blood*, 1985; 66:367–372 [LIT.001.0505]. Preliminary Report paragraphs 7.83 and 7.84

<sup>113</sup> Presented in part at the American Society of Hematology meeting, San Antonio, Tex December 1981.

to be no indication to alter current therapy patterns because of concern over plasma product-related liver disease. It was acknowledged that the comparative lack of severity of the histopathological findings in the materials studied might not be entirely reassuring in the light of other recent findings.<sup>114</sup> In retrospect, the reservations underestimated the seriousness of the potential progression of the disease, but the assessment reflected a common view at the time among haemophilia specialists.

**15.107** The difference of opinion apparent in these reports reflected differences of experience and approach. Dr Aledort (and other haemophilia clinicians in the USA and Europe) had seen the transformative effect of factor concentrates on the lives of patients and had good reason to take a sanguine view of the possible adverse effects of NANB Hepatitis. Dr Alter, Dr Dienstag (two leading US authorities in their field) and others were, however, beginning to understand that what they saw of post-transfusion NANB Hepatitis in liver biopsies might represent a serious cause for concern.

**15.108** Dr Dienstag and Dr Alter reviewed the position reached in 1986, after the publication of hundreds of articles. Acknowledging at the outset that 'our understanding of NANB hepatitis is still unsettled and evolving...' and that '[s]trikingly clear is just how much we do not know about NANB hepatitis', they wrote presciently:

In the decade since its discovery, the concept of NANB hepatitis has evolved from that of a benign elevation of aminotransferase activity to that of a serious disease with significant long-term consequences. The longer patients are followed, the more obvious it becomes that [chronic active hepatitis] and cirrhosis are a very real part of the natural history of NANB hepatitis.<sup>115</sup>

**15.109** Since the recognition of NANB Hepatitis as a distinct form of viral hepatitis, studies had shown biochemical evidence of chronic hepatitis in approximately 50% of cases related to transfusion. Among those with chronic ALT elevations who were biopsied, approximately 60% had chronic active hepatitis, cirrhosis, or both. Overall, 10–20% of those with chronic ALT elevations had cirrhosis on initial or repeat biopsy.<sup>116</sup> Among cases described in published reports, of 20 patients in whom cirrhosis had developed after transfusion, five had died of liver failure. The finding in Dr Aledort's study<sup>117</sup> of liver biopsies from persons with haemophilia, that cirrhosis had developed in 15% of patients, a prevalence similar to that obtained in non-haemophilia, transfused populations, was said to be alarming. Dienstag and Alter commented:

Although there is a divergence of opinion as to the progressive nature of ... histologic abnormalities in hemophiliacs, a substantial proportion of these patients end up with cirrhosis, an unequivocal histologic diagnosis that leaves little room for argument....<sup>118</sup>

**15.110** The authors noted, furthermore, that indirect evidence for an association between NANB Hepatitis and hepatocellular carcinoma (liver cancer) was beginning to accumulate.<sup>119</sup>

**15.111** On 20 June 1986, the *MMWR* reported 13 cases of NANB Hepatitis among patients who had undergone cardiovascular surgery and, because of bleeding during surgery, had received Factor IX produced by Alpha Therapeutic Corporation.<sup>120</sup> The report noted that clotting factor preparations had frequently been linked to the transmission of NANB Hepatitis. In haemophilia patients who routinely received commercial factor preparations, episodes of NANB Hepatitis were common: as many as 50% were observed to go on to develop signs of chronic liver disease. Studies in first-exposed haemophilia patients and in surgical patients who received clotting factor preparations, suggested that the risk of NANB Hepatitis might be close to 100%.<sup>121</sup>

**15.112** The balance was moving towards the views of Dr Alter and his colleagues.

### *NANB Hepatitis aetiology and natural history: UK and other research*

**15.113** The discussion of reported research from sources other than those from the USA is necessarily more diffuse and it is difficult to form a view of the circulation and acceptability of other opinion from outside the UK in this period. As with the US source material, much of the relevant published research is described in Chapter 7 of the Preliminary Report and is not repeated in this chapter unless necessary.

### **Haemophilia**

**15.114** In the UK, Dr Gunson's report to the European Health Committee of the Council of Europe on 25 June 1982 commented that there appeared to be a low contamination rate of NANB Hepatitis in the UK in patients receiving cryoprecipitate but a high rate following transfusion of Factor VIII concentrates prepared from large pools.<sup>122</sup> He suggested that avoiding the use of large-pool fractions for those with mild coagulation defects was a practical way of reducing the incidence of post-transfusion NANB Hepatitis. The discussion that followed did not deal with the natural history of infection.

**15.115** Comment on the natural history of NANB Hepatitis came in September 1982 when Mannucci and colleagues published a follow-up to their 1978 report on liver disease in haemophilia patients.<sup>123</sup> One patient had died of gastrointestinal bleeding. Four of the remaining 10 patients continued to have chronic persistent hepatitis, two had developed chronic lobular hepatitis and there was spontaneous improvement of disease activity in three cases. The majority were asymptomatic. The emphasis in the authors' comments was similar to that reported by Aledort and colleagues. Progressive disease was not the rule in haemophilia patients with chronic NANB Hepatitis and only two patients had died from cirrhosis. This view was supported by data from the UKHCDO which showed that apparently only two haemophilia patients had died of cirrhosis in the UK between 1976 and 1980.<sup>124</sup>

**15.116** At that stage, it was thought that there was no evidence that chronic liver disease was a prominent cause of morbidity and death in haemophilia patients. The authors speculated that the course of chronic liver disease in those patients who had progressive

<sup>123</sup> Mannucci et al, 'Nonprogressive course of non-A, non-B chronic hepatitis in multitransfused hemophiliacs', *Blood*, 1982; 60:655–658 [LIT.001.0543] Preliminary Report paragraphs 7.21 and 7.22

<sup>124</sup> Rizza et al, 'Treatment of haemophilia and related disorders in Britain and Northern Ireland during 1976-80: report on behalf of the directors of haemophilia centres in the United Kingdom', *British Medical Journal*, 19 March 1983 [LIT.001.0234]

disease might be unfavourably influenced by their continuous exposure to blood-borne viruses and by repeated and long-lasting challenge by allogenic plasma proteins transfused in the concentrates, a suggestion that was also to become prominent in relation to AIDS in the early stages of study of that disease.<sup>125</sup>

**15.117** An official from the Public Health Laboratory Service (PHLS) wrote to the DHSS on 10 January 1983, enclosing the terms of a letter which it was proposed to send to *The Lancet*.<sup>126</sup> The draft commented:

There is no evidence of which we are aware that indicates that re-exposure to non-A, non-B hepatitis viruses present in concentrates received by patients with severe coagulation defects predisposes them to a higher incidence of serious chronic liver disease than patients with mild disease who receive less frequent transfusions. If the 'hepatitis reduced' concentrates prove to be associated with a reduced risk of non-A, non-B hepatitis with an insignificant loss of factor VIII activity, then these products should be reserved in the first instance for patients with no prior exposure to factor VIII concentrates or those who have received less than 5 batches of factor VIII in the past. Similar considerations would apply to NHS factor IX concentrate, but we have as yet no accurate information concerning the risk of non-A, non-B hepatitis associated with NHS factor IX concentrate. Another study in patients undergoing open heart surgery reported an attack rate of 100% non-A, non-B hepatitis related to transfusions of factor IX concentrate, whereas an attack rate of 3% was reported in patients who received transfusions of whole blood only.<sup>127</sup>

**15.118** It appears that the cut-off point of five batches was an empirical idea not, at that stage, based on rigorous scientific analysis. In a practical sense it provided a ready test of whether a patient had been infrequently transfused. The official's comments were reasonably consistent with the predominant view among haemophilia doctors in the UK in 1982–83 (with the exception of Preston and colleagues).<sup>128</sup> Haemophilia doctors increasingly recognised the high frequency of NANB Hepatitis infection but still considered its clinical consequences to be benign.

**15.119** Among haemophilia experts, significant comment on the natural history of NANB Hepatitis was advanced with the publication in 1983 of the paper by Richard Stevens and others reporting on their study of 12 haemophilia patients in Manchester, 'Liver disease in haemophiliacs: an overstated problem?'<sup>129</sup> All patients were multi-transfused and all had persistently abnormal liver function tests. Otherwise, patient selection was random. The historical background that effectively set out the position challenged, as reported by Mannucci, Lesesne, Preston, Spero, Schimpf and others, was said to be:

The increasing use of plasma products has resulted in an improved quality of life for many haemophiliacs. However, over the past decade there have been reports of a high prevalence of abnormal liver function tests in multitransfused haemophiliacs. Liver biopsies carried out in such patients have been reported as

<sup>125</sup> The 'immune overload hypothesis' is discussed, in the context of HIV/AIDS, in Chapter 11, *AIDS Aetiology*.

showing that up to half the cases are associated with abnormal liver histological appearances including chronic active hepatitis.<sup>130</sup>

**15.120** The outcome of the Stevens study was different. Only one patient showed evidence of severe chronic active hepatitis with progression to cirrhosis although a further four patients showed some evidence of mild chronic active hepatitis. On the basis of their findings, the authors stated that the results represented a much lower incidence of severe histological liver damage than many previous reports. They suggested that the true incidence of severe histological liver abnormality in multi-transfused haemophilia patients might be less than previously reported but similar to the more recent results of 115 liver biopsies carried out worldwide by Dr Aledort and colleagues.<sup>131</sup>

**15.121** At the beginning of 1983, pharmaceutical companies continued with practical preparations for the introduction to the market of modified products, reflecting the underlying view that the agent of transmission was a virus that was susceptible to inactivation. It was anticipated in government that the companies would seek to avoid the requirement for a formal clinical trial by the use of transfusions on a named patient basis (an expanded access programme for as-yet unlicensed drugs).<sup>132</sup>

**15.122** On 28 September 1983 Dr Craske produced the Annual Report for 1982–83 of the UKHCDO Hepatitis Working Party.<sup>133</sup> The report referred to the Oxford study, started in 1981, of hepatitis in infrequently treated haemophilia patients.<sup>134</sup> The findings had confirmed that the risk of contracting NANB Hepatitis from Factor VIII concentrates on first exposure was 100%, whether NHS or commercial Factor VIII was used. An internationally based trial of Hyland/Travenol's heat-treated Factor VIII (Hemofil T)<sup>135</sup> had commenced and an Armour heat-treated product (Factorate HT)<sup>136</sup> would soon be available for evaluation. Mannucci had already announced at the European Society of Haematology that the Hyland product transmitted NANB Hepatitis.<sup>137</sup> The problem of AIDS had begun to overshadow these developments, however. Directors required to consider the ethical problem of exposing persons with mild haemophilia to commercial material. The ethical problem was expressed as follows:

Since the only way of ensuring the susceptibility to non-A, non-B viruses is by using patients who have not previously received factor VIII or IX concentrate, a choice will have to be made between using heat treated products from commercial sources, which might carry a small risk of AIDS transmission, or using NHS concentrate which appears to carry a 100% chance of transmitting non-A, non-B hepatitis.<sup>138</sup>

<sup>138</sup> UK Haemophilia Working Party Annual Report 1982/3 [SNF.001.0948] at 0952; Preliminary Report, paragraph 7.45

**15.123** The report also referred to the Behringwerke heat-treated product mentioned above (paragraph 15.48).

**15.124** A report of the Oxford study was published on 10 December 1983.<sup>139</sup> The factual information presented was the same in all material respects as Dr Craske's report to the UK Haemophilia Hepatitis Working Party on 28 September 1983.

**15.125** The Discussion section of the published study included the following observations:

This study shows a high incidence of non-A non-B hepatitis in patients treated with factor VIII who had either not received it previously or had received it only infrequently. All of those who received commercial concentrates developed hepatitis regardless of their transfusion history; those who received NHS factor VIII were less likely to develop hepatitis if they had been treated before. All nine patients who received NHS factor VIII for the first time developed hepatitis, while only eight out of the 15 who had received it previously did so .... It may be that the pool size of NHS concentrates has now increased to the point where the benefit conferred by using plasma from volunteer donors has been lost.<sup>140</sup>

**15.126** The discussion indicated the basis for many of the assertions of risk that were made at about this time and for some time thereafter. The fact that all nine 'virgin' patients developed NANB Hepatitis was the basis of the view that the exposure of new patients to Factor VIII concentrates, of UK origin or otherwise, carried a '100%' risk. The conjecture that the pool size of NHS concentrates may by then have increased to the point where the benefit conferred by using plasma from volunteer donors had been lost reflects the same attitude. These were important observations at the time.

**15.127** In an accompanying *BMJ* editorial,<sup>141</sup> Dr Jones (Newcastle Haemophilia Centre) stated that liver function tests were 'abnormal in most severely affected haemophiliacs who have had repeated transfusions'. Most post-transfusion hepatitis was now thought to be NANB. Despite the gloomy observations of others, he thought that probably most of the observed changes in liver function represented chronic persistent (perceived to be non-progressive) rather than chronic active (and progressive) hepatitis. Mortality from liver disease remained low. Life expectancy in haemophilia was near normal, due entirely to the widespread introduction of Factor VIII concentrates and comprehensive care.

**15.128** It is apparent that by the end of 1983 haemophilia specialists and the medical profession generally had been informed that UK Factor VIII concentrate was highly likely to transmit NANB Hepatitis virus(es) in a majority of those previously transfused and in every person transfused with Factor VIII for the first time. With the benefit of hindsight, however, some commentators were in error as to the long-term prognosis. Because they did not understand the natural history of NANB Hepatitis they thought that it could be inferred, from the observations over the year following infection which showed that most liver tests stabilised and no one remained very 'ill' with hepatitis, that NANB Hepatitis was unlikely to be a serious, long-term problem. That was despite the voices from Sheffield

<sup>139</sup> Fletcher et al, 'Non-A non-B hepatitis after transfusion of factor VIII in infrequently treated patients', *British Medical Journal*, 1983; 287:1754–57 [LIT.001.0239]. Preliminary Report paragraphs 7.50 and 7.51.

<sup>140</sup> Ibid [LIT.001.0239] at 0241

<sup>141</sup> Jones, 'Acquired immunodeficiency syndrome, hepatitis, and haemophilia', *British Medical Journal*, 1983; 287:1737–38 [LIT.001.0243]

suggesting that this might not be the case and the prevalence of chronic active hepatitis (known by liver doctors to carry a risk of progression), with or without cirrhosis, in 20–35% of the haemophilia patients whose biopsy results had been reported in the series of published studies.

### Post-transfusion hepatitis

**15.129** As in the USA, early reports of post-transfusion hepatitis in this period were associated with major surgical procedures. In 1982, a five-year study by Giuseppe Realdi and others (Padua, Italy) on post-transfusion hepatitis was reported as showing that five of 21 patients with post-transfusion hepatitis followed for five years or more developed cirrhosis.<sup>142</sup>

**15.130** In 1983 the 7th edition of Patrick Mollison's standard textbook on blood transfusion medicine in the UK was published.<sup>143</sup> In a discussion of NANB Hepatitis, it was noted that:

As a rule, non-A, non-B hepatitis is symptomatically mild. Patients seldom need to be admitted to hospital. Nevertheless, up to 60% of cases have abnormal [ALT] levels for more than 1 year; if a liver biopsy is taken, most of the cases show histological evidence of a significant chronic liver disease and approximately 10% show features of cirrhosis.<sup>144</sup>

**15.131** The textbook noted the results<sup>145</sup> of the USA-based TTV Study of 1981:

Although non-A, non-B hepatitis develops in some patients who have received only blood from donors with normal ALT levels, it can be deduced that at least 21% of cases of transfusion-associated hepatitis might be prevented by excluding only 3% of the present donor population ....<sup>146</sup>

**15.132** It was also noted by Mollison that the minimum carrier rate of the NANB Hepatitis virus in volunteer blood donors in the USA had been estimated to be 1.6% and in commercial blood donors to be 5.4%.<sup>147</sup> The textbook further noted that there was evidence that non-A, non-B viruses played a smaller part in the UK than in the USA.<sup>148</sup>

**15.133** At the meeting of the UK Blood Transfusion Services' Working Party on Transfusion Associated Hepatitis on 27 September 1983, there was discussion of 'apparent non-A non-B hepatitis-like illnesses' in patients receiving high doses of intravenous human normal immune globulin.<sup>149</sup> Incidence of infection was higher than in intramuscular infusion, the other standard route of delivery. The signs noted were early transaminitis. Dr Thomas

<sup>142</sup> Realdi et al, 'Long-term follow-up of acute and chronic non-A, non-B post-transfusion hepatitis: evidence of progression to liver cirrhosis', *Gut*, 1982; 23:270–275 [LIT.001.0528]. Preliminary Report, paragraph 7.10 gives further details

<sup>148</sup> Mollison, *Blood Transfusion in Clinical Medicine*, 7th edition, 1983, Blackwell Scientific Publications, page 774; Preliminary Report, paragraphs 7.31–7.33

<sup>149</sup> Human normal immune globulin is a therapeutic product which provides antibodies to Hepatitis A, rubella, measles and other viruses for specific types of patient; broad-spectrum passive protection to premature babies; broad-spectrum protection for immunocompromised patients; and other beneficial uses. Importantly for this discussion, it is a product prepared from moderate-to-large plasma pools (often containing 1000 donations or more).

thought that the picture was similar to that seen of commercial Factor VIII concentrates from the USA.<sup>150</sup>

**15.134** There were several published reports on these patients.<sup>151</sup> The most relevant for present purposes is a paper by Dr Andrew Lever and others, published much later, on 10 November 1984.<sup>152</sup> They reported that the illnesses were acute NANB Hepatitis, clinically and histologically identical to the short-incubation NANB Hepatitis seen in haemophilia patients receiving Factor VIII concentrates. The comments made included the then common view that there were at least two parenterally transmitted NANB Hepatitis viruses with different incubation periods. In relation to the natural history of the postulated short incubation form of the disease, it was stated that the disease was usually mild during the acute phase but that a large proportion, usually greater than 80%, would go on to acquire chronic lesions, sometimes culminating in cirrhosis. Of the postulated long-incubation type, the paper stated that it was also a mild illness, but 20–40% of patients still had abnormal liver function progressing sometimes to cirrhosis.

**15.135** Leaving aside the distinction between the types, later disproved, the paper placed a new stress on the natural history of the disease and a growing appreciation in the UK of the potential for serious outcomes associated with NANB Hepatitis infection. Given the date of its publication, the paper may have had more significance for the general dissemination of knowledge in the next sub-period, 1984–1985, but the commentary is illustrative of the views of this group of UK experts at about the end of 1983. The paper made a further comment of some importance:

[T]he finding that the virus can be transmitted in [human normal immune globulin] concentrates suggests either that the general population has a very low level of antibodies to the putative virus or that such antibodies are not virus-neutralising.<sup>153</sup>

**15.136** The second proposition was correct and the first was not irrelevant to other work at the time. A prospective study of post-transfusion hepatitis in patients undergoing heart surgery, reported in November 1983, found that the incidence of post-transfusion NANB Hepatitis after cardiac surgery was low compared with similar studies in other countries, suggesting that blood transfusion using blood collected locally from volunteers rarely led to clinically significant chronic liver disease.<sup>154</sup>

### 1984–1985

**15.137** The next two years saw some convergence of opinion among experts from a number of groups. The National Institute for Biological Standards and Control (NIBSC) met on 9 February 1984 to discuss the infectious hazards of blood products.<sup>155</sup> This important body gave scientific advice to the UK licensing authority and to the Committee on the Safety of Medicines. The importance of the meeting lay in bringing together a range of

<sup>150</sup> Notes of the Minutes of the UK Working Party on Transfusion Associated Hepatitis Held at Edgware on Tuesday 27 September 1983 [SNB.001.3443] at 3444–45

<sup>151</sup> Preliminary Report paragraphs 7.44 and 7.47.

<sup>153</sup> Ibid [LIT.001.0449]

<sup>154</sup> Collins et al, 'Prospective study of post-transfusion hepatitis after cardiac surgery in a British centre', *British Medical Journal*, 1983; 287:1422–24 [LIT.001.0212]. The incidence was 14.6% in one study in the USA, in Italy 17.8%, in Sweden 18.9% and 30.4% in Japan. A study in the Netherlands had found a low incidence of post-transfusion NANB Hepatitis (3.4%) which was closely comparable with the results of the Newcastle study. Preliminary Report paragraph 7.48

<sup>155</sup> NIBSC Meeting Minutes [SNB.004.8628]; Preliminary Report, para 7.55

presentations by specialist contributors. There were a number of significant contributions from those whose views had already influenced opinion in specialist forums.

**15.138** Dr Thomas (NIBSC) commented on the finding that the first exposure to factor concentrate, from whatever source, was associated with 100% infectivity with NANB Hepatitis. Dr Craske (PHLS, Manchester) provided data on the incidence of jaundice in persons with haemophilia in the UK from 1969 to 1979, and on the prevalence of NANB Hepatitis in the haemophilia population. Dr McClelland (SNBTS, Edinburgh) presented statistical data on the risk to haemophilia patients of transmitting NANB Hepatitis by blood transfusion and factor therapy. In discussion, Dr Eibl (Imuno, Vienna) commented on European experience of managing the blood donation programme. Dr Lane (BPL, Elstree) and Dr Schild (NIBSC) gave information about current work by fractionators aimed at minimising infectious hazards. There were no executive decisions relating to NANB Hepatitis but the NIBSC had collected much relevant information which would be available to government and to the bodies the NIBSC advised. It was an important stage in the development of information available to inform decision-making bodies in the UK.

### Haemophilia

**15.139** On 9 January 1984 a report was prepared by the Blood Products Sub-Committee of the Haemophilia Society which reviewed the policy of the Society in relation to the supply of blood products in the UK.<sup>156</sup> It was recorded that the main ground for believing that British-made products were medically preferable to imported products had been the greater risk of hepatitis infection, particularly Hepatitis B infection, from imported products. Improved screening for anti-HBV and improved donor selection procedures employed by manufacturers had resulted in commercial material being of comparable standard to NHS material.<sup>157</sup> The report commented that:

- Hepatitis B remained a transfusion hazard.
- Regarding the risk of NANB Hepatitis, recent developments suggested that UK material was no better (and might be worse) than imported material.

**15.140** In light of the discussion, the Sub-Committee suggested that there was no continuing reason to prefer NHS products. A manuscript note on a copy of the report said that this view would not help convince Regional Health Authorities (in England and Wales) to use the NHS product.

**15.141** Trials of the new, possibly safer, imported products became an important topic for Haemophilia Directors. Details are set out in the Preliminary Report and need not be repeated in full.<sup>158</sup> On 29 March 1984, the Chairmen of the UKHCDO and its Hepatitis Working Party asked for cooperation between the Haemophilia Centre Directors in coordinating trials of the new heat-treated blood products.<sup>159</sup> The base-line information on transmission was that there was still a 63% infection rate of NANB Hepatitis on first exposure in patients who had not previously received Factor VIII concentrate.

<sup>156</sup> Haemophilia Society Blood Products Sub-committee Report [DHF.001.5151]

<sup>157</sup> This was a reference to the Oxford study: Fletcher et al, 'Non-A non-B hepatitis after transfusion of factor VIII in infrequently treated patients', *British Medical Journal*, 1983; 287:1754-57 [LIT.001.0239] Preliminary Report paragraph 7.54

<sup>158</sup> Preliminary Report, paragraphs 7.57, 7.58

<sup>159</sup> Memo [DHF.002.8963]

**15.142** On behalf of the UKHCDO, Dr Craske proceeded to coordinate a prospective study of hepatitis in previously infrequently treated haemophilia patients.<sup>160</sup> By that stage, clinical trials had been completed on only one product. A total of eight products were in preparation or available for trial, including two NHS Factor VIII concentrates. Dr Craske sought the cooperation of Directors in identifying suitable patients for coordinated trials.

**15.143** In reply to the UKHCDO's request for cooperation in entering suitable patients into trials, Professor Christopher Ludlam (Edinburgh Haemophilia Centre) replied that he wished to reserve places for any patients he might have, for testing Scottish product.<sup>161</sup> His patients constituted a group that had been treated consistently with PFC Factor VIII and he was unwilling to jeopardise the advantages of their selection for study exclusively in relation to the Scottish product by exposing them to imported products. Professor Cash was anxious to have a study carried out in the West of Scotland.<sup>162</sup> He wished to assess the incidence of hepatitis and transaminitis in 'virgin' (previously untreated) haemophilia patients who received SNBTS 'hepatitis reduced' Factor VIII by coordinated clinical trials. There were, however, few qualifying patients in Scotland as a whole at the time, or in any given period, available for the sort of study proposed by Professor Cash. The study was aimed at collecting information about what was clinically essential treatment for these patients. Most existing patients receiving factor concentrates for haemophilia therapy had by this date been infected with NANB Hepatitis. Only new patients requiring treatment by factor concentrates for the first time, might benefit if the modified product was effective in removing or reducing the risk of transmission. They constituted a small group at any given time.

**15.144** These studies and proposed studies treated NANB Hepatitis as a threat to the health of haemophilia patients that had to be dealt with. They were not primarily concerned with the natural history of the disease or with the analysis of its progression. At this stage, one way of tackling the risk was the development of effective virus-inactivated products. That depended on government funding and, in that context, the balancing of risk and benefit was relevant. The views of SHHD medical advisers were reflected in a memorandum by Dr Bell dated 23 May 1984, commenting on the Common Services Agency's case for funding the production of heat-treated Factor VIII.<sup>163</sup> Dr Bell noted that, at that time, nearly all newly-treated haemophilia patients became infected with NANB Hepatitis, though not usually of dramatic severity, and that about 40% also showed evidence of infection with Hepatitis B. He said that the longer-term effects of such infection in people with haemophilia were not known with certainty because, until relatively recently, haemophilia patients had little prospect of living into middle or old age. However, he thought that a significant proportion of non-haemophilia patients infected with Hepatitis B went on to suffer severe liver impairment which, apart from the personal aspect, made significant demands on health care resources. The clear implication was that the experience of haemophilia patients was likely to be similar.

**15.145** In 1985, reports were published that reflected the results of studies of the incidence of infection. The work of Peter Kernoff and others at the Royal Free Hospital, London, is dealt with in the Preliminary Report.<sup>164</sup> They found that all of their haemophilia

<sup>164</sup> Preliminary Report, para 7.76; Kernoff et al, 'High risk of non-A, non-B hepatitis after a first exposure to volunteer or commercial clotting factor concentrates: effects of prophylactic immune serum globulin', *British Journal of Haematology*, 1985;60:469-479 [LIT.001.0800]

patients treated with commercial Factor VIII developed acute NANB Hepatitis. Ten out of 12 patients who were prescribed NHS concentrate also developed acute NANB Hepatitis. The results were not surprising given the size of the donor pools. The report by Massimo Colombo and others of their study of transmission of NANB Hepatitis by Hyland/Travenol's Hemofil T Factor VIII confirmed that NANB Hepatitis had an attack rate close to 100% in haemophilia patients not previously exposed to blood or blood derivatives who were given that commercial product.<sup>165</sup> Preston and others reported similar results in two previously untreated patients who were given Armour's heat-treated product, Factorate.<sup>166</sup>

**15.146** The focus of interest changed in June 1985 with the publication by Charles Hay and others (Sheffield) of 'Progressive liver disease in haemophilia: an understated problem?' The authors' discussion is informative. They stated:

Our observations show that progressive liver disease is a potentially serious problem in haemophilia. Of 79 haemophilic patients .... 17 had evidence of progressive liver disease (9 cirrhosis, 8 CAH). Serial liver biopsies showed progression of [Chronic Persistent Hepatitis] to [Chronic Active Hepatitis] and cirrhosis within a period of 2 – 6 years.

The prevalence of abnormal liver function tests in haemophiliacs increased rapidly with the widespread introduction of factor VIII and IX concentrates in the mid-1970s. These abnormalities are believed to arise as a sequel to viral infection transmitted by blood products .... Almost all previously untreated haemophiliacs acquire NANB hepatitis after administration of factor VIII concentrate, and regular users may have multiple attacks from more than one NANB agent.<sup>167</sup>

**15.147** As indicated in the Preliminary Report, Hay and others discussed their clinical findings and compared their results to those of Mannucci and colleagues in 1982, discussed above. The discussion continued:

Cirrhosis may take several years to develop and it is consequentially not surprising that cirrhosis was more common in our series than in earlier studies with shorter periods of follow-up. This is especially important in view of the fact that the high prevalence of liver disease probably dates from the introduction of factor VIII concentrates ....

A notable feature of our series is that 4 patients with CPH have shown progression to CAH and cirrhosis; this is at variance with the generally accepted view that CPH is benign and non-progressive and leads us to speculate that repeated exposure to hepatitis viruses may modify the usually benign course ....

Although few reports of death attributable to liver disease in haemophilia have appeared, we predict that this will become more common.<sup>168</sup>

<sup>165</sup> Preliminary Report, paragraph 7.81; Colombo et al, 'Transmission of non-A, non-B hepatitis by heat treated factor VIII concentrate' *The Lancet*, 1985;ii:1-4 [LIT.001.0369]

<sup>166</sup> Preliminary Report, paragraph 7.82; Preston et al, 'Non-A, non-B hepatitis and heat treated concentrates', *The Lancet*, 27 July 1985:213 [LIT.001.0464]

<sup>167</sup> Hay et al, 'Progressive liver disease in haemophilia: an understated problem?', *The Lancet*, 29 June 1985:1495-98 [LIT.001.0335] at 0336. The title was, as Dr Hay stated in testimony on Day 8 (page 5), in response to the 1983 publication by Stevens et al (Manchester) entitled 'Liver disease in haemophiliacs: an overstated problem?' *British Journal of Haematology*, 1983; 55:649-655 [LIT.001.0008]; Preliminary Report paragraphs 7.78-7.80

<sup>168</sup> Hay et al, 'Progressive liver disease in haemophilia: an understated problem?', *The Lancet*, 29 June 1985: 1495-98 [LIT.001.0335] at 0337

**15.148** Mannucci's response is set out in paragraph 7.85 of the Preliminary Report. Since this is an important juncture in the published debate, it is important to note the details:

[S]ince our patients had similar ALT pattern and length of follow-up as those investigated by Hay et al, we think that other factors must be considered to explain the different courses of liver disease. The fact that our patients were considerably younger than those studies by Hay et al ... suggests that the degree of liver damage might be inversely related to the age at which patients become infected. Children with chronic hepatitis B tend to have high levels of virus replication in the liver without severe liver disease. So, in view of the many epidemiological similarities between hepatitis B and non-A, non-B hepatitis, it is not surprising that children with non-A, non-B infection tend to have less progressive and more "tolerated" liver disease than adults with the same infection.<sup>169</sup>

**15.149** The findings by Hay's group were not challenged. A possible explanation of the different outcome was suggested. At least in the case of adult haemophilia patients, the risk of progressive liver disease had been shown to be greater than previously anticipated. In time, this was to become clearer and, as indicated in Chapter 13, *Knowledge of Viral Hepatitis Now*, paragraphs 13.68–13.73, it is now established that the rate of progression is related to age in patients infected with HCV.

### Post-transfusion hepatitis

**15.150** In 1984, 'Notes on Transfusion principles and practices' was published jointly by the DHSS, Scottish Home and Health Department (SHHD) and the Welsh Office on behalf of the NBTS and SNBTS.<sup>170</sup> The 'Notes on Transfusion' discussed Hepatitis A and Hepatitis B in the context of donor selection, and commented:

Very similar illnesses can also be caused by other viruses including the so-called 'non-A non-B' viruses. The latter are also transmissible by transfusion, but as yet no specific laboratory tests have been developed to identify them. The incubation period is also variable extending up to 70 days or more. The clinical course may be acute, or chronic leading to cirrhosis.<sup>171</sup>

**15.151** The notes concluded with instructions on the collection of samples and on the reporting duties of clinicians finding hepatitis. The notes were concerned with practical guidance but would have brought to the attention of any transfusion doctor that there was a risk of transfusion-transmission of viral hepatitis generally and NANB Hepatitis in particular.

**15.152** In its annual report to the Office of the Chief Scientist of the DHSS, lodged in May 1984 by the London School of Hygiene and Tropical Medicine, it was stated:

The development of specific serological tests for detection of markers of infection with parenterally-transmitted forms of non-A, non-B hepatitis continues to elude laboratory workers in this field. Similarly the viruses have not yet been identified.<sup>172</sup>

<sup>169</sup> Manucci and Colombo, 'Liver Disease in Haemophilia', *The Lancet*, 5 October 1985 [LIT.001.1656]

<sup>170</sup> Notes on Transfusion [DHF.003.0394]

<sup>171</sup> Ibid [DHF.003.0394] at 0412

<sup>172</sup> Annual Report to the Office of the Chief Scientist of the Department of Health and Social Security on the Work of the Hepatitis Laboratory [DHF.003.0101] at 0107

**15.153** The development of specific laboratory tests for NANB Hepatitis remained a matter of high priority.

**15.154** In marked distinction to the developments in haemophilia, there was less appreciation among those involved with transfusion, in the UK generally and in Scotland in particular, of the nature of the risks presented by NANB Hepatitis. In July 1984 Dr Follett (laboratory virologist at the Regional Virus Laboratory, Ruchill Hospital, Glasgow) and Dr Brian Dow (Senior Technician, SNBTS, Glasgow) presented the final report on a study of 'Non-A Non-B Hepatitis in the West of Scotland'. The first part of the report examined all notified clinical cases diagnosed as likely to be due to non-B post-transfusion hepatitis in the region over four years. Excluding four haemophilia patients who had been multiply transfused with Scottish and imported blood products, they concluded that there were nine likely cases. The second part of the report contained an examination of ALT levels, and the results of other serological tests, of 10,655 blood donations. They found elevated ALT levels in 367 individuals (3.4%), and markedly elevated levels in 96 cases (0.89%).<sup>173</sup>

**15.155** Interestingly, prison session donors (a number of whom recognised as intravenous drug users) showed 10 times more donations with grossly elevated ALT levels than among other groups of donor. These results discouraged SNBTS from continuing to hold donor sessions in prisons to collect blood for transfusion purposes.<sup>174</sup>

**15.156** The study was poorly funded, however, and limited in scope. There was no follow-up of the 10,655 blood donations. No valid conclusions could be drawn as to the frequency of post-transfusion NANB Hepatitis. Drs Follett and Dow concluded, however, that on the basis of the nine reported clinical cases, NANB Hepatitis was very rare in the region. The authors recognised that sub-clinical forms of post-transfusion hepatitis probably occurred but were not notified.<sup>175</sup> Like previous studies based on reported incidents, this work probably missed the vast majority of cases of post-transfusion NANB Hepatitis. The sub-clinical forms of infection were noted but not taken into account, although it later transpired that they were the dominant component in the actual pattern of transmitted infection.

**15.157** Most unfortunately, the report and the erroneous conclusion drawn, that NANB Hepatitis was very rare in the region, were firmly grasped by the SHHD and its medical advisors and held to be valid, until about 1987–88. This was to lead to a significant lack of understanding of the post-transfusion NANB Hepatitis problem and a marked reluctance to fund other studies.

**15.158** Dr McClelland (SNBTS, Edinburgh) presented a rather similar view to that of Drs Follett and Dow at the 18th Congress of the International Society of Blood Transfusion held in Munich in July 1984.<sup>176</sup> He stated that the risk of Hepatitis B following transfusion of blood or its components was extremely rare. Coagulation factor concentrates had a very high risk of transmitting NANB Hepatitis but clinically apparent post-transfusion NANB Hepatitis was a small problem. A few transfused patients developed asymptomatic elevations of liver enzymes but the importance of that remained undefined.

<sup>176</sup> Abstracts of the 18th Congress of the International Society of Blood Transfusion [SNB.008.6696] at 6697. Preliminary Report paragraph 7.62

**15.159** Scottish blood transfusion experts were not alone in expressing such views in 1984. An article by Drs Barbara and Tedder (North London Regional Transfusion Centre and University College and Middlesex School of Medicine, London) published in October 1984<sup>177</sup> commented that most NANB Hepatitis infections were not apparent and were only detected by mild elevation of transaminase levels. It was noted that raised transaminase levels could be caused by other viruses or by factors such as drugs, alcohol, obesity and medications. There were major uncertainties about the consequences of NANB Hepatitis, according to these authors who stated that the usually mild acute NANB Hepatitis infections in haemophilia patients would have little significance but for their possible association with the development of chronic hepatitis. However, they stated, even that was frequently self-limiting and resolved within two years in most cases.

### Summary

**15.160** By the end of 1985, different views were beginning to emerge, especially among haemophilia clinicians and other experts such as Dr Lever and colleagues. It seems however, that the majority, reputable view from leading groups around the world, outside the USA, was that the likelihood was fairly remote that NANB Hepatitis would become a very significant long-term problem, with many individuals developing cirrhosis. Most reports had lacked any lengthy follow-up and had concentrated on the acute changes which researchers saw in blood tests and liver biopsies over the month or two of the initial illness. While there were a few voices suggesting that chronic liver disease/cirrhosis attributable to NANB Hepatitis was becoming, or likely to become, more and more of a problem, these were in a minority. However, to a great extent, the opinions expressed reflected the researchers' natural biases: differences were of the 'glass half full, glass half empty' variety.

**15.161** It seems reasonable to conclude that, until the end of 1985 at the earliest, it was a very tenable position to hold that infusion of Factor VIII concentrates presented a risk of significant long-term liver disease but that fatal liver disease was a very small risk. This position is exemplified by Dr Craske's remark that, to his knowledge, only two patients with haemophilia had died of cirrhosis in the previous 10 years.<sup>178</sup> It is likely that the view of the majority of these authorities (for most groups anyway) was that the relatively few deaths from cirrhosis among haemophilia patients during the 1970s and early '80s had been caused by the 'rump' of the Hepatitis B cases.

**15.162** At that time, commentators were all, to some extent, working in the dark. Research produced findings that could be, and were, described. However, the significance of the findings, in terms of the natural history of NANB Hepatitis, was often unclear.

**15.163** In the period between 1975 and 1985, increasingly sensitive tests for the Hepatitis A virus (HAV) and Hepatitis B virus (HBV) were developed. In particular, as the range of HBV viral markers improved, there was increasing understanding of which markers indicated present infection and infectivity and which indicated past infection and immunity. However, until the mid-1980s it was unclear what the various markers which commentators were describing for present infection with Hepatitis B in the blood signified in assessing the long-term prospects for the patient.

---

<sup>177</sup> Barbara and Tedder, 'Viral Infections Transmitted by Blood and Its Products', *Clinics in Haematology*, 1984; 13: 693–707 [LIT.001.3739]

<sup>178</sup> Meeting on the Infectious Hazards of Blood Products NIBSC, 9 February 1984 [SNB.004.8628] at 8630

**15.164** The significance of the various histological appearances of the liver – chronic persistent hepatitis, chronic lobular hepatitis, and chronic active hepatitis – in terms of likelihood of progression to serious liver disease or regression to normal, was also unclear at that time. Few of the patients studied in this period, either in the USA or in Europe, had any specific symptoms. Such evidence as had emerged on relatively long-term follow-up (up to five years) suggested that in most individuals chronic liver inflammation engendered by the putative NANB Hepatitis virus(es) would generally die down. It was only towards the later part of the period that suggestions began to emerge that, in perhaps 10% of those chronically infected, irreversible liver damage – cirrhosis – could develop.

**15.165** Although the vast majority, if not all, of the clinical studies of NANB Hepatitis associated with Factor VIII use, up to the end of 1985, had set out descriptions of liver disease acquired in real time before the arrival of HIV/AIDS, by late 1985 all major groups were preoccupied with HIV/AIDS and NANB Hepatitis was regarded as a less urgent problem. Furthermore, as was about to become apparent, co-infection with NANB Hepatitis and HIV/AIDS was to become relatively common and was to further complicate understanding of liver disease for the next two or three years.

**15.166** At the end of this period, there remained substantial deficits in knowledge of NANB Hepatitis and its natural history. The clinical dilemma as to whether to provide treatment with available human blood-derived therapeutic products remained but the perceived risks of infection had increased. At the meeting called by NIBSC on 9 February 1984, Dr Thomas expressed the problem clearly: 'The undoubted therapeutic benefit of Factor VIII concentrates was clouded by a well recognised side-effect, namely hepatitis, and also, more recently, by AIDS.'<sup>179</sup>

**15.167** There were, however, widely differing views at that meeting about the nature and the extent of the risks to patients. Dr McClelland's estimate of the risk of transmitting NANB Hepatitis by blood transfusion was 1 in 100 and he commented that the risks for haemophilia patients were much greater because of their exposure to large numbers of donors. In relation to hepatitis, Dr Craske reported that 30–40% of UK haemophilia patients had abnormal liver function tests, indicative of possible chronic liver damage. However, by 1983 only two haemophilia patients had died of liver disease in 10 years. Throughout this period the low mortality reported in haemophilia patients from complications of hepatitis had a significant impact on the assessment of risk/benefit for the patient receiving blood products.

**15.168** The 7th edition of Professor Sherlock's *Diseases of the Liver and Biliary System* was published in 1985. It provides a useful summary of the position regarding NANB Hepatitis in the UK at that time. At the end of the period discussed in this chapter, it can be taken to represent the information likely to have been available to the general body of clinicians and others in the UK concerned with liver disease at this time. Professor Sherlock noted four clinical types of NANB Hepatitis (among many).<sup>180</sup> Two were enterically spread and can be ignored for present purposes. The two parenterally spread types were (a) a blood transfusion related type with a relatively long incubation period, and (b) a type associated with the administration of blood products to haemophilia patients, distinguished by a short incubation period. The clinical course of infection was the same in each case. The acute attack was mild but could occasionally be fulminant (rapidly progressing). Approximately

<sup>179</sup> NIBSC Meeting on the Infectious Hazards of Blood Products, 9 February 1984 [SNB.004.8628]

<sup>180</sup> Sherlock S, *Diseases of the Liver and Biliary System*, 7th ed, Blackwell, Oxford, page 270

68% of patients developed chronic hepatitis. In 19%, this progressed slowly and almost without symptoms to cirrhosis. Fluctuating transaminases were said to be typical of the chronic state. It was commented, significantly, that a relationship to hepatocellular cancer had not been established. It was noted that there was no test for NANB Hepatitis and that there had been limited progress both in diagnosis and in assessing treatment.

**15.169** Professor Sherlock's preface was dated October 1985 and the text is likely to have been completed some months earlier. It is unlikely to have taken account of research in the second half of the year in which Professor Sherlock was not involved. Nevertheless, although it cannot be assumed that there was general knowledge of up-to-date research, the emerging position by the end of 1985, in both the USA and the UK, was that:

- There was increasing concern in some quarters about the potential seriousness of NANB Hepatitis, whether following blood transfusion, in relation to which there was more knowledge and more concern in the USA, or in haemophilia treatment.
- Almost all haemophilia patients who regularly received treatment with concentrates were likely to have been infected by the disease.
- First generation heated concentrates continued to transmit NANB Hepatitis.
- The debate over the benefits and drawbacks of screening blood donors for surrogate markers of NANB Hepatitis continued.

**15.170** The last two topics are discussed in Chapters 23 and 27. The next chapter takes up the developing story of NANB Hepatitis after 1985.

## CHAPTER 16

### KNOWLEDGE OF VIRAL HEPATITIS 3 – 1986 ONWARDS

#### Introduction

**16.1** This chapter continues the account of the development of knowledge of non-A, non-B Hepatitis (NANB Hepatitis) from 1986 through to the discovery of the Hepatitis C virus (HCV) and beyond. Some of the later developments described are also reflected in Chapter 13, *Knowledge of Viral Hepatitis Now*. They are repeated here for the context in which they arose and particularly to provide chronological references for developments in screening blood and testing blood donors, further developments in the treatment of blood components and products and other topics dealt with separately.

**16.2** As noted in the previous chapter (paragraphs 15.108–15.110), in 1986 expert opinion in the USA was moving towards general support for surrogate testing as a means of excluding from the donor pool as many donors infected with NANB Hepatitis virus(es) as possible.<sup>1</sup> That development resulted in the general introduction of surrogate screening of blood for alanine transaminase (ALT),<sup>2</sup> and testing of donors for antibodies to the Hepatitis B virus. That course was not to be followed in the UK however, although in other respects opinion in the UK began to change in the same period. Correspondence in *The Lancet* in February 1986 marked the beginning of a change in attitudes towards NANB Hepatitis.

#### Changing attitudes towards non-A, non-B Hepatitis

##### *Correspondence in The Lancet*

**16.3** A letter by Klaus Schimpf (Heidelberg, West Germany) published on 8 February 1986,<sup>3</sup> expressed agreement with the report in 1985 by Dr Charles Hay and his colleagues in Sheffield<sup>4</sup> that progressive liver disease in haemophilia patients was an understated problem. In Schimpf's study 52 biopsies were carried out on 45 patients between 1972 and 1985. There were signs of subsided hepatitis in 24% of the patients, of chronic persistent hepatitis in 27% and of progressive liver disease in 29% (16% chronic active hepatitis, 13% cirrhosis). Schimpf also noted that the multi-centre study by Louis Aledort and others had come to a similar conclusion regarding the frequency of cirrhosis.<sup>5</sup>

**16.4** The same edition of *The Lancet* contained an update on the condition of 12 patients who had developed NANB Hepatitis after treatment with a new intravenous gammaglobulin preparation produced by the Blood Products Laboratory, Elstree (BPL, the manufacturer of NHS blood products in England).<sup>6</sup> At least half of the patients had evidence of progressive liver disease, with cirrhotic changes in three. While specific to patients with primary hypogammaglobulinaemia (an immune deficiency characterised by

<sup>1</sup> A surrogate marker is a directly measurable physical entity (usually measured in a blood test) that has a statistical association (correlates) with a disease where it is not possible to test directly for the disease or where any direct test would be problematic. See Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*.

<sup>2</sup> Proteins synthesised in liver cells, normally present in low levels in the blood, which become elevated when the liver is disordered by virus infection or other disorders of the liver.

First reported in 1984 by Lever et al (including Webster), 'Non-A, Non-B hepatitis occurring in agammaglobulinaemic patients after intravenous immunoglobulin', *The Lancet*, 1984; 1062–1064 [LIT.001.0449]

a reduction in gamma globulins and treated with blood products), the letter emphasised that NANB Hepatitis was a serious complication that should be controlled by discarding plasma donations with raised ALT levels.

**16.5** An editorial in *The Lancet* of 2 August 1986 stated:

The risk of contracting [NANB Hepatitis] from factor VIII and IX concentrates was first recognised ten years ago. The requirement for large pools of plasma, of up to 7000 donations in the UK ... and even larger pools with some commercial preparations, has produced attack rates approaching 100% in recipients after first exposure to unheated factor VIII. The acute illness was often mild .... Unfortunately, it is now clear that there is a substantial long-term risk of chronic sequelae, such as chronic active hepatitis and cirrhosis of the liver. Reports of serial liver biopsies in patients regularly treated with factor VIII and IX suggest that the risk of serious chronic liver disease may be as high as 16%.

....

Despite intensive research, the virus or viruses associated with non-A, non-B (NANB) hepatitis have not been isolated or characterised.<sup>7</sup>

**16.6** By the end of 1986, informed opinion in the USA (as typified by Alter and colleagues) and in parts of Europe had shifted decisively to reflect suspicion that the long-term progression of chronic NANB Hepatitis infection was not benign but severe, whether following blood transfusion or in haemophilia patients.

### *Increasing concern*

**16.7** In 1987, the 8th edition of the standard UK textbook on blood transfusion was published.<sup>8</sup> Post-transfusion NANB Hepatitis was said to be present when, between two and 26 weeks after transfusion, two consecutive blood samples showed a twofold increase in ALT levels – effectively the approach to diagnosis adopted in the USA. That method of diagnosis was described by Patrick Mollison, the author of this authoritative text, as ‘most unsatisfactory’ and was said to have led to ‘a great deal of uncertainty about the true incidence’ of post-transfusion NANB Hepatitis. It was estimated that NANB agents had caused 20–42% of sporadic cases of hepatitis in the USA,<sup>9</sup> compared with 13% within the UK.<sup>10</sup> Mollison wrote:

[NANB post-transfusion hepatitis] is usually mild and asymptomatic during the acute phase .... However, prospective studies in the USA have shown that the chronic sequelae of [NANB post-transfusion hepatitis] may be serious. Over 50% of patients develop chronic hepatitis as judged by persisting or fluctuating rises in [ALT] levels lasting for at least 1 year after onset of the disease and in most for more than 3 years .... Although the chronic phase of [NANB post-transfusion hepatitis], like the acute phase, tends to be mild,<sup>11</sup> some patients

develop severe chronic liver disease and 10% of these patients progress to cirrhosis which is generally milder than alcoholic cirrhosis.<sup>12</sup>

**16.8** It was noted that the available data were based on biopsies in very small numbers of patients.<sup>13</sup>

**16.9** In a letter to the *British Medical Journal (BMJ)* published on 14 February 1987, Dr John Gillon and Dr Brian McClelland (both of the Edinburgh and South East Scotland Blood Transfusion Service) commented that only one study of the long-term consequences of post-transfusion NANB Hepatitis infection had been reported.<sup>14</sup> This was a reference to the Alter study.<sup>15</sup> The letter narrated that of the 50% of cases which became chronic as evidenced by raised ALT levels persisting for more than six months, 10–15% might be expected to show evidence of clinically important liver disease. As noted in the Preliminary Report,<sup>16</sup> applied to the UK these figures were almost certainly an overestimate. However, it is of greater importance that at this time the authors did not have locally relevant data to draw on. There was still considerable uncertainty but some growing understanding. At an international symposium on viral hepatitis and liver disease held in London in May 1987, Dr Alter said:

NANB remains a frustrating and perplexing dilemma. Nonetheless we know a little more about its physical properties, we know considerably more about its clinical outcome, and we know of multiple ways in which it can be inactivated. What we do not know exactly is where to go next, or what can be done to create the breakthrough that will allow progress with NANBH to parallel that with hepatitis B and hepatitis A.<sup>17</sup>

**16.10** There were other international meetings at the time, reflecting increasing concern. As noted in the Preliminary Report, the European Health Committee of the Council of Europe held its 21st meeting between 29 June and 1 July 1987.<sup>18</sup> The prevailing uncertainty was reflected in the extract of a report of the 10th meeting of the Committee of Experts on Blood Transfusion and Immunohaematology circulated for that meeting.<sup>19</sup>

### *Scientific developments: discovery of the Hepatitis C virus*

**16.11** The scientific background was about to change. On 10 May 1988, the Chiron Corporation announced that:

Scientists at Chiron Corporation have identified, cloned and expressed proteins from a long-sought blood-borne hepatitis non-A, non-B virus, and have developed a prototype immunoassay that may lead to a screening test for hepatitis non-A, non-B antibodies ....<sup>20</sup>

<sup>20</sup> News Release dated 10.05.88 from Chiron Corporation announcing the cloning of the NANB Hepatitis virus [PEN.016.0290]

**16.12** Scientific details were not published at that time,<sup>21</sup> although the report of the Chiron discovery in *Nature* said: 'The search for the elusive viral agent responsible for [NANB] hepatitis may be over.'<sup>22</sup> Throughout the remainder of 1988 there was little in the way of published material on HCV and no technical support for the claim. In the UK public sector, research was focused on virus inactivation. There was powerful support for that approach. In an article published in *The Lancet* in December 1988, Dr Alter and others stated:

Because [of] the increasing number of direct and indirect donor screening measures required to protect the blood supply, the most promising approach to the reduction of transfusion-associated disease is the biophysical removal or biochemical inactivation of hepatitis and other blood transmitted viruses ...<sup>23</sup>

**16.13** Work in that area is discussed in Chapters 23 and 24.

**16.14** In the short term, the Chiron report was scarcely noted in published statements by commentators who remained pre-occupied with the natural history of the disease. Although there was growing appreciation that there were risks associated with the use of plasma products, the prevailing view among Scottish Home and Health Department (SHHD) medical staff remained that NANB Hepatitis was generally benign – a view that would have received support from the 7th edition of Professor Sherlock's book (discussed in the last chapter at paragraph 15.168). In Scotland, there had been a report of four cases of infection that might have been transmitted by intravenous immunoglobulin manufactured at the Protein Fractionation Centre (PFC, the manufacturer of NHS blood products in Scotland), Edinburgh, during 1987.<sup>24</sup> In an internal memorandum to Mr Hamish Hamill at the SHHD dated 30 August 1988, Dr John Forrester noted that the product was under suspicion of transmitting NANB Hepatitis, but concluded:

[T]his particular hepatitis is so benign, at least in the short term, that evidence of transmission has to be specially sought, the patient not being ill at all in the ordinary sense.<sup>25</sup>

### *Progressive disease as an aspect of the natural history of non-A, non-B Hepatitis*

**16.15** There were still differences of view among medical practitioners generally about the seriousness of NANB Hepatitis infection. An editorial in *The Lancet* in December 1988 summarised the recent history of 'Chronic liver disease and haemophilia'.<sup>26</sup> The editorial noted that while acute post-transfusion hepatitis and chronic increases in liver enzyme concentrations had long been associated with both Factor VIII and Factor IX infusion, those caring for haemophilia patients were slow to accept chronic progressive liver disease as an important complication. It was noted that few haemophilia patients had any signs or symptoms of liver disease, deaths from hepatic failure were rarely reported and raised ALT levels were attributed to chronic persistent hepatitis rather than chronic active hepatitis. The results from studies of early series of patients undergoing liver biopsy

<sup>21</sup> Scientific details of the discovery were not published until April 1989: Choo et al, 'Isolation of a cDNA clone derived from a blood-borne non-A non-B viral hepatitis genome', *Science*, 1989; 244:359–362 [LIT.001.0629] and Kuo et al, 'An assay for circulating antibodies to a major etiological virus of human non-A, non-B hepatitis', *Science*, 1989; 244:362–364 [PEN.017.2764]

<sup>25</sup> Memo [SGH.002.4672] at 4673

<sup>26</sup> 'Chronic liver disease and haemophilia', *The Lancet*, 1988; 1465–66 [LIT.001.3838]

were generally reassuring in that most of them showed either chronic persistent hepatitis or mild chronic active hepatitis, with little to suggest severe liver damage.<sup>27</sup> However, as noted in paragraph 16.3 above, Hay and colleagues (1985) had documented a significant progression from chronic persistent hepatitis to chronic active hepatitis to cirrhosis.<sup>28</sup> Their assessment was echoed by Schimpf (paragraph 16.3, above).<sup>29</sup>

**16.16** Similar figures were provided in a contemporaneous report from Dr Elizabeth Miller and colleagues in London (1988).<sup>30</sup> The editorial stated:

The evidence that chronic progressive liver disease is an important complication of haemophilia treatment is therefore becoming increasingly persuasive. Furthermore, experience with other types of viral hepatitis suggests that cirrhosis and hepatocellular carcinoma may first appear decades after infection.<sup>31</sup>

**16.17** Opinion was moving towards acceptance of more progressive disease as an aspect of the natural history of NANB Hepatitis.

### Reactions to the Chiron announcement and further scientific developments

**16.18** There were mixed responses to the initial announcements of Chiron's discoveries. The American Association of Blood Banks (AABB) reported that, while there remained some scepticism about the results, a leading expert in the field, Harvey Alter (US National Institutes of Health) had said that Chiron's identification of the NANB Hepatitis protein was 'what we've been looking for for 10 years... one has to be skeptical but the data I've seen looks very good'.<sup>32</sup> The AABB commented:

Because Chiron has not yet published its results some scepticism remains about their findings....

Health experts agree that further testing still needs to be performed because the protein identified may be one of several capable of causing non-A, non-B hepatitis.<sup>33</sup>

**16.19** At the end of 1988 publication of scientific analysis of Chiron's work was still awaited.

**16.20** Dr Brian Dow, at the time a Senior Grade Scientific Officer at the West of Scotland Blood Transfusion Service, gave evidence that he thought he had been aware of Chiron's discovery at this time but had been unwilling to believe it was true until the first generation tests were available.<sup>34</sup> It appears that this was a common attitude.

<sup>27</sup> Reference was made to the following reports: (1) Lesesne et al, 'Liver biopsy in hemophilia A', *Annals of Internal Medicine*, 1977; 86:703–707 [LIT.001.3712]; (2) Preston et al, 'Percutaneous liver biopsy and chronic liver disease in haemophiliacs', *The Lancet*, 1978; 592–594 [LIT.001.0387]; (3) Spero et al, 'Asymptomatic structural liver disease in hemophilia', *New England Journal of Medicine*, 1989; 293:1373–78 [LIT.001.0177]; (4) Mannucci et al, 'Nonprogressive course of [NANB] chronic hepatitis in multitransfused hemophiliacs', *Blood*, 1982; 60:655–658 [LIT.001.0543] and (5) Stevens et al, 'Liver disease in haemophiliacs: an overstated problem?', *British Journal of Haematology*, 1983; 55:649–655 [LIT.001.0008]

<sup>34</sup> Day 67, page 90

**16.21** Details of Chiron's discovery and resulting test were not published until the following year when, on 21 April 1989, Qui-Lim Choo and others published scientific details of the isolation of the genome of HCV.<sup>35</sup> At the same time, George Kuo and others (Chiron, US National Institutes of Health and others) published details of an assay to detect antibodies to HCV.<sup>36</sup> The test had been developed by Ortho Diagnostics Systems (Ortho) in conjunction with Chiron.

### *The science of discovery*

**16.22** Chiron had inoculated a chimpanzee with a serum sample<sup>37</sup> from a patient with post-transfusion hepatitis and had cloned the putative virus. Serum was taken from another patient who had recovered from post-transfusion NANB Hepatitis and was assumed to have produced antibodies to the NANB agent. The antibodies were 'labelled' and introduced to the putative virus. An appropriate reaction was observed which showed the connection required to verify the hypothesis that the cloned material was, or included, the agent of transmission of NANB Hepatitis.<sup>38</sup>

**16.23** It is appropriate to set out the story a little more fully to indicate why the discovery had such an impact on understanding of the infection. At the outset of the process, the subject, a patient who was known to have had a transfusion, was believed to have become ill with NANB Hepatitis about three weeks after the procedure. To test that hypothesis, serum from the patient was injected into a chimpanzee called Rodney. Rodney developed hepatitis, an essential step in removing any doubt whether the episode in the patient was due to an infectious agent, since it demonstrated transmissibility.<sup>39</sup>

**16.24** A sample of serum was taken from Rodney and RNA and DNA were extracted. At that stage it was not known whether the postulated transmissible agent was an RNA or DNA virus.<sup>40</sup> Reverse transcriptase, an enzyme that allows RNA to convert into DNA, was added to the genetic material extracted from Rodney's serum, with the result that the whole genetic material present was DNA. The DNA would include chimpanzee DNA but it would also include the DNA of the putative virus if it were present. That material was then put into plasmids, a vehicle that enabled the expression (synthesis) of the DNA code of whatever proteins had been introduced, in the case of a virus in the same way as the virus would normally synthesise proteins.<sup>41</sup> The product of that exercise was then put into E-coli for propagation in the hope that, as the bacteria reproduced, the introduced DNA from the chimpanzee and the putative virus would also reproduce genetically in the bacterial cells. This was the only way in which the viral DNA would encode for the protein which was part of the structure of the putative virus.<sup>42</sup>

**16.25** At that stage, serum was taken from a patient who was known to have had post-transfusion NANB Hepatitis and who was assumed to have developed antibodies to the virus. Using an appropriate ligand, a radioisotope or an enzyme label that creates a coloured substrate, the antibodies were labelled as human virus antibodies. When introduced to

<sup>39</sup> Professor Thomas – Day 52, pages 21–22

<sup>40</sup> Ibid pages 22–23

<sup>41</sup> Ibid page 29

<sup>42</sup> Ibid pages 22–24

the material propagated in *E. coli*, the labelled antibodies were expected to differentiate and bind to any human virus protein or DNA present and not to chimpanzee DNA. Such a reaction would be identified radioactively or by chemi-luminescence.<sup>43</sup> The reaction was observed in a tiny minority of the wells into which the samples were dispensed but showed the necessary connection.

**16.26** Chiron's overall procedures and approach to finding the virus and its procedures were not fundamentally unique: many researchers had tried similar approaches, but without success. There may have been many reasons for failure, including the use of virus material that did not include an antigenic component common to all the genotypes of the virus.<sup>44</sup> However, so much effort had been expended in searching for the putative virus in so many centres worldwide that by 1987–88 many people had given up believing that there was a virus, preferring the explanation that a chemical reaction caused the transaminase rise in patients in much the same way as some drugs used in medication can cause hepatitis.<sup>45</sup> Chiron's advantages were having 'well-pedigreed' chimpanzee sera to establish the transmission of hepatitis through passage (the sequential process from the initial patient through two chimpanzees in succession which proves the existence of a transmissible agent); and sera containing a large amount of virus. The infective serum from the first chimpanzee was diluted until it no longer transmitted hepatitis,<sup>46</sup> enabling Chiron to calculate the amount of virus in the initial sample.<sup>47</sup> For this work Chiron was granted a patent and lengthy and complex litigation followed. So far as is material, the challenge to the patent failed.<sup>48</sup>

**16.27** The publication of details of the Chiron discoveries marked the beginning of a period of research, both into the characteristics of HCV and into the effectiveness of markers of HCV infection and corresponding developments in treatment. The term 'Hepatitis C' almost entirely supplanted 'NANB Hepatitis' in the discussion of liver disease following Chiron's breakthrough in the understanding of NANB Hepatitis. The terms have never, however, been truly synonymous.

**16.28** The articles by Choo and others and Kuo and others referred to above were highly technical. The identification of the virus depended on the characterisation of the clones produced. The conclusions, and claims, were significant:

Thus, our data indicate that clones 5-1-1 and 81 are derived from the genome of a blood-borne NANBH virus that we now term the hepatitis C virus (HCV) ... Our present data showing that the virus contains a positive-stranded RNA molecule of at least 10,000 nucleotides is consistent with it being related to the togaviridae or flaviviridae .... The cDNA clones reported here were obtained in the absence of prior knowledge concerning the virus, the viral genome, and the presence of circulating viral antibodies. As such, this represents cloning without prior characterization of the infectious agent.<sup>49</sup>

<sup>46</sup> The process referred to as 'titration'.

<sup>47</sup> Professor Thomas – Day 52, pages 26–28

<sup>48</sup> *Chiron Corporation and Others v Murex Diagnostics Ltd and Others and Chiron Corporation and Others v Organon Teknika and Others* (1996) R.P.C. 535. The scientific background to the discovery is more fully set out in Lord Justice Morritt's judgment, from page 589. Professor Thomas, who gave evidence at the trial, commented on the novelty of granting a patent for a natural sequence: Day 52, pages, 28–29. He also expressed reservations about claims extending the scope of the patent to the whole virus, since the Chiron artefact lacked the 3 prime coded region essential for replication: Day 52, pages 37–38. However, detailed analysis of the validity of the patent is beyond the scope of this Report.

<sup>49</sup> Choo et al, 'Isolation of a cDNA clone derived from a blood-borne non-A, non-B viral hepatitis genome', *Science*, 1989; 244: 359–362 [LIT.001.0629] at 0631

**16.29** In retrospect, the Chiron discovery was to prove more significant than was appreciated at the end of the 1980s and into the early 1990s. Other topics continued to attract attention. The scientific basis for the work was not readily understood and general understanding only developed over time. The background to Chiron's work set out above helps to explain the difficulties. Professor Thomas encapsulated the discovery in a brief, and somewhat concentrated, statement:

[Chiron] reported the cloning of HCV in 1989, by antibody probing of an expression library made from a reverse transcribed RNA extract of the serum of an infected chimpanzee initially inoculated with a serum sample from a patient with post-transfusion hepatitis (PTH). The antibody source was a serum specimen from a subject who had recovered from post-transfusion NANB hepatitis and was assumed to have produced antibodies to NANB agent.<sup>50</sup>

**16.30** The concepts, and the language, reflect a highly sophisticated knowledge of the biology of virus replication. The current understanding of the position has been set out in Chapter 13, *Knowledge of Viral Hepatitis Now*. However, this would have been science understood by only a few at the end of the 1980s.

**16.31** Chiron had achieved a significant, and inventive, development in knowledge of HCV infection but the work was incomplete: the whole virus had not been identified. In Chiron's experiments, the antigen recognised by the antibody in the recovered patient's serum was in the region NS4, one of the enzymes known as proteases that came, in time, to be targeted by protease inhibitors which increase substantially patients' response rates to treatment by impairing the ability of the virus to reproduce. Not all genotypes of HCV<sup>51</sup> have NS4 proteins, however, and this was to affect the usefulness of early forms of the assay developed. Without a sophisticated knowledge of cell biology, incomplete research findings were almost bound to leave even the most interested and careful commentators with reservations about the discovery.

**16.32** In the context of transfusion-related transmission and blood product therapy, post-transfusion Hepatitis C now appears to explain most if not all cases of what was NANB Hepatitis viral infection. Before the discovery of HCV, however, many people infected with the virus would not have been labelled as 'non-A, non-B' patients: there were few NANB Hepatitis diagnoses.<sup>52</sup> Alcohol and alcoholic liver disease were often associated with hepatitis and many patients were labelled as having 'alcoholic liver disease' alone, where two (or possibly more) risk factors would now be recognised, giving rise to much of the stigma associated with infection.<sup>53</sup>

### Unresolved issues in non-A, non-B Hepatitis

**16.33** The balanced view of the state of knowledge in 1989, as reflected in the eighth edition of Sherlock's *Diseases of the Liver and Biliary System*, published that year but continuing to reflect to a considerable extent views expressed in earlier editions, was that NANB Hepatitis was still 'ill defined'.<sup>54</sup> As regards the parenteral type of NANB Hepatitis, Professor Sherlock stated:

<sup>50</sup> Professor Thomas' report on Hepatitis C [PEN.017.1071]

<sup>51</sup> As noted in Chapter 13, *Knowledge of Viral Hepatitis Now*, HCV exhibits considerable genetic heterogeneity. Seven distinct genotypes of HCV have been identified.

<sup>52</sup> Professor Hayes – Day 78, pages 46–47

<sup>53</sup> Ibid pages 47–48

<sup>54</sup> Sherlock, S. *Diseases of the Liver and Biliary System*, 8th edition, 1989, page 301

The causative agent has not hitherto been identified ... [although] a viral genomic clone has been isolated from infected plasma and liver. This encodes the antigen associated with non-A, non-B viral hepatitis in man and chimpanzees.<sup>55</sup>

**16.34** It is likely that the text was written before publication of the more definitive Chiron papers in 1989 and Professor Sherlock's comment reflects information provided in the original *Science* announcement. Chiron's discoveries were not presented in her text as resolving the aetiology of NANB Hepatitis.

**16.35** On the other hand, Professor Sherlock's analysis of the clinical manifestations of infection with NANB Hepatitis presented a more serious and accurate picture than before. It was now thought that 60% of patients would have raised serum transaminases one year after infection. In 68% the disease became chronic and cirrhosis developed in 20%.<sup>56</sup> She stated that prognosis was very variable. In some cases, the diseases were benign with spontaneous biochemical improvement over one to three years. In others, chronic persistent hepatitis and chronic active hepatitis could convert to more serious disease and even go on to cirrhosis. In general, however, despite biochemical evidence of disease, the patient was asymptomatic and the development of hepatic failure was rare. Hepatocellular cancer had been recorded but was exceedingly rare.<sup>57</sup> In contrast to the seventh edition, a relationship to hepatocellular cancer was now acknowledged.

**16.36** Another insight into the perception of NANB Hepatitis among virologists in the UK at the end of 1988 was provided in a paper entitled 'Unresolved issues in non-A, non-B hepatitis' delivered by Professor Arie Zuckerman (Professor of Microbiology, Royal Free Hospital School of Medicine, London), presented at the Second International Symposium on Viral Hepatitis and Hepatocellular Carcinoma in Taipei in December 1988.<sup>58</sup>

**16.37** Professor Zuckerman stated that NANB Hepatitis was the most common form of hepatitis occurring after blood transfusion in some parts of the world (possibly 90% where blood donations were screened for HBsAg by sensitive tests) and that there was evidence of at least two transmissible agents.<sup>59</sup> It occurred in haemodialysis and other units and could be transmitted by therapeutic plasma components. He noted that there was preliminary information of an association with hepatocellular carcinoma, and commented generally on NANB Hepatitis:

Although in general the illness is mild and often subclinical or anicteric, severe hepatitis with jaundice does occur and the infection is a significant cause of fulminant [rapidly progressing] hepatitis. There is considerable evidence that the infection may be followed in many patients ... by prolonged viraemia and the development of a persistent carrier state. Studies of histopathological sequelae of acute non-A, non-B hepatitis infection revealed that chronic liver damage, which may be severe, may occur in as many as 40 – 50% of the patients.<sup>60</sup>

<sup>55</sup> Ibid page 326

<sup>56</sup> Ibid page 327

<sup>57</sup> Ibid page 367

<sup>58</sup> Zuckerman, A, 'Unresolved Issues in Non-A Non-B Hepatitis' [SNB.001.9490]

<sup>59</sup> Ibid [SNB.001.9490] at 9492–93

<sup>60</sup> Ibid [SNB.001.9490] at 9493

**16.38** Professor Zuckerman said that clinical evidence of more than one type of the disease was based on observation of multiple attacks of hepatitis in individual patients and experimental laboratory research. He dismissed argument based on incubation periods. His own explanation of the occurrence of multiple attacks was subsequently shown to be wrong. It later transpired that multiple attacks of Hepatitis C could occur because of insufficient host immunity to different genotypes of HCV rather than because of the existence of more than one viral species. However, that knowledge depended on advanced genetic research that still lay in the future. Like Professor Sherlock in the eighth edition of her book, Professor Zuckerman was writing before publication of the scientific data supporting Chiron's claims. It appears that neither Professor Sherlock nor Professor Zuckerman was willing at that stage to arrive at final conclusions on what was known of Chiron's discoveries.

**16.39** It is apparent that, despite the novelty of Chiron's science, or perhaps because of it, there was not immediate and universal acceptance of its validity. The initiative, in terms of fundamental research into HCV, continued to lie with Chiron and the US Centers for Disease Control.

**16.40** The second meeting of the Advisory Committee on the Virological Safety of Blood (ACVSB) took place on 22 May 1989.<sup>61</sup> Professor Zuckerman's Taipei paper was circulated along with a second paper, from an unidentified but clearly official source,<sup>62</sup> and members were given the results of the Council of Europe questionnaire prepared by Dr Gunson and the report of the Committee of Experts on Blood Transfusion and Immunohaematology from May 1987. In addition, scientific data from Chiron was available. The article published by Choo and others in *Science* was referred to and the accompanying paper noted:

The data suggests that NANB hepatitis agent is similar to the togaviridae or flaviviridae. The authors refer to this virus as hepatitis C virus.<sup>63</sup>

**16.41** The discussion of NANB Hepatitis was brief, so far as reported in the minute of the meeting. It was recorded that members had advised that, although colleagues in the USA considered that only one virus caused NANB Hepatitis, there might be two or more. The question whether there was more than one agent of transmission continued to arise. An editorial in *The Lancet* on 5 August 1989, 'Will the real hepatitis C stand up?', discussed the question whether there was a distinct short incubation agent with reference to reports of observations of apparently different incubation periods.<sup>64</sup>

**16.42** However, in general, interest came increasingly to focus on the Chiron/Ortho test. It was in that context that political interest was aroused by articles in *The Guardian*<sup>65</sup> and *The Scotsman*<sup>66</sup> in August 1989 that were likely to cause public concern. The article in *The Guardian*, for example, stated that '6000 people last year may have received blood transfusions contaminated with hepatitis C'. There was official reaction to the media comment.

<sup>66</sup> 'Doctor Says Hepatitis Blood Tests Could Cost Millions', *The Scotsman*, 25 August 1989 [SGH.002.8007]

**16.43** On 23 August Mr George Tucker (SHHD) sent a memorandum to Mr Michael Forsyth, MP, then Under-Secretary of State in the Scottish Office with responsibility for health: 'Testing of blood donations – test for Hepatitis C'.<sup>67</sup> Mr Tucker dealt with the claim in *The Guardian*: the statement was said to be 'unnecessarily alarmist', as it assumed that one per cent of all donations came from donors who were infectious (and not simply carriers) and that they passed on the antigen, and not just the antibody, in their donation. It also said that only a minority of those infected with Hepatitis C displayed any symptoms either in the short or long term. The memorandum further noted that the prevalence of HCV in the population had not been established and nor had the role of blood in its transmission. The UK Health Departments, along with the UK blood transfusion services, were said to be examining all the available data. The main focus of the memorandum was the position of the SHHD and the DHSS on testing, and that may explain the brevity of the information provided on the prevalence and consequences of infection.

**16.44** From the position adopted by Professor Zuckerman at the end of 1988 through to September 1989, expert opinion was consistent in the UK and more widely. Dr Ruthven Mitchell (SNBTS, Glasgow) attended and produced a report of proceedings at an international meeting on HCV, organised by Ortho and held in Rome on 14–15 September 1989.<sup>68</sup> There had been discussion at the conference on the prevalence and sequelae of NANB Hepatitis. Dr Mitchell's report stated that about 10% of persons transfused developed NANB Hepatitis, which could be of two forms, an acute form and a chronic form.<sup>69</sup> The incubation time varied from a few weeks to months. About 90% of post-transfusion hepatitis was due to the NANB Hepatitis virus or viruses. About 50% of those would become chronic and, of those, 20% would develop cirrhosis or some long-term liver impairment. Prevalence of the Hepatitis C antibody (anti-HCV) varied among different countries. Patients in the highest risk categories had the highest prevalence of anti-HCV. People with haemophilia had an anti-HCV prevalence of 60–80%.

**16.45** Dr Gunson reported the proceedings of the Rome meeting to the meeting of the Advisory Committee on Transmission Transmitted Diseases (ACTTD)<sup>70</sup> on 9 October 1989. His report included a recommendation in the following terms:

The Committee is asked to approve the routine testing of blood donations for anti-HCV in principle and request the National Directors in England and Scotland to arrange for the simultaneous introduction of the tests at an appropriate time when a policy for handling the seropositive donors has been defined.<sup>71</sup>

**16.46** It would be almost two years before the simultaneous introduction of testing of blood donations for anti-HCV was introduced throughout the UK. This delay is discussed in Chapter 31, *The Introduction of Screening of Donated Blood for Hepatitis C*.

<sup>67</sup> Memo [SGH.002.8012]

<sup>68</sup> Report of Meeting [SNB.001.8678]. Dr Mitchell produced a further report [SNB.002.4553]. Dr Gunson also prepared a report on the Rome meeting. Dr Gunson's original report [SNB.006.1456] was considered at the 3rd meeting of the ACTTD on 9 October 1989 and a revised version of his report was considered at the 4th meeting of the ACVSB on 6 November 1989 [SNF.001.1383] at 1401.

<sup>69</sup> Dr Mitchell's report of the incidence of NANB Hepatitis at 10% was grossly inflated, if intended. A more accurate estimate would have been 1%.

<sup>70</sup> The background to the setting up of ACTTD is set out in Chapter 27, *Surrogate Testing for non-A, non-B Hepatitis*.

<sup>71</sup> Report [SNB.006.1456] at 1460

**16.47** After this time, there was a change in the proportions of individuals reported to be affected by adverse sequelae of infection. On 8 January 1991 at the sixth meeting of the ACTTD, a paper prepared by Dr Gillon (SNBTS, Edinburgh) on counselling of donors was also discussed.<sup>72</sup> Dr Gillon was a member of the SNBTS Working Party on Donor Counselling for HCV, along with Drs R Crawford, G Galea and J Davidson. The fourth draft of their report<sup>73</sup> found that there were thought to be at least two NANB Hepatitis viruses, but that Hepatitis C was almost certainly the most common form, thought to be responsible for around 70% of post-transfusion hepatitis. This misapprehension occurred because first generation antibody tests detected only part of the variable 'non-structural' part of the virus – NS4 – which was only present, in this form, in about 70% of HCV cases overall (see paragraph 16.31 above). Once subsequent antibody tests to less variable parts of the virus had been developed, it was realised and accepted that almost all post-transfusion NANB Hepatitis could be ascribed to HCV. The report stated that most people with NANB Hepatitis would be asymptomatic but that some would go on to develop long-term liver damage: around 10–15% of those with post-transfusion NANB Hepatitis might eventually develop significant liver disease. The prevalence of carriage of NANB Hepatitis in the general donor population was not known. The prevalence of confirmed anti-HCV in UK donors was likely to be around 1 in 1000 (0.1%). Preliminary studies on Scottish blood donors showed that approximately 0.5% were repeatedly positive.

**16.48** By this stage, however, expert opinion was moving towards adopting HCV screening and the numerical data on prevalence came to be discussed in that context. Effective HCV testing of blood donors was introduced on 1 September 1991 and formed a new setting for study of the infection. Material became available to assess the prevalence of disease and prospective studies of the progress of infection became more practicable. The introduction of testing did not, however, resolve the question of the historic prevalence of infection nor of the numbers of patients likely to survive with the infection.

**16.49** In the 1990s, many countries initiated 'look-back' studies to identify patients who had received infected blood,<sup>74</sup> in an attempt to assess the prevalence of HCV infection in their populations. Work in south east Scotland found that look-back for Scottish patients would be feasible and practicable. After review on 11 January 1995, UK Ministers announced a national look-back following the East of Scotland Blood Transfusion Service model.<sup>75</sup> This topic is discussed in Chapter 35, *An Investigation into the Steps Taken to Identify the Individuals who were Infected (Look-back)*.

**16.50** The UK national HCV look-back exercise carried out between 1995 and 1998 resulted in the creation of the National Hepatitis C Register as a research tool at the Health Protection Agency (HPA), Colindale, in 1998. The initial UK exercise was closed to new entrants in 1998.

**16.51** Anonymised data from all patients identified by the look-back exercise as having contracted Hepatitis C as a result of transfusion were entered into the central register at the HPAs Centre for Infections. Systematic collection of clinical data using standardised report forms allowed data to be gathered in a uniform way approximately every two years.

<sup>72</sup> Minutes [SNB.001.8770] at 8772; Draft Report [SNB.001.8779]

<sup>73</sup> Fourth Draft Report (extracts) [SNB.001.8803]

<sup>74</sup> Professor Thomas – Day 53, page 38. The purpose of look-back was to trace NHS patients who had received blood, blood components or blood products derived from donations by donors who tested positive for Hepatitis C antibodies after 1 September 1991, when screening was introduced, and who had previously donated blood which was found by retrospective testing also to have been infective. See Chapter 35, *An Investigation Into the Steps Taken to Identify the Individuals who were Infected (Look-back)*.

<sup>75</sup> Press release [SNF.001.2191]

The data, along with mortality data for patients on the register and for controls, allowed the clinical course of HCV infection to be established and risk factors for progressive disease to be investigated.

**16.52** The Scottish exercise continued formally until 1998. On 10 June that year Dr Aileen Keel, Senior Medical Officer, SHHD, wrote to Professor Ian Franklin, Medical and Scientific Director, SNBTS.<sup>76</sup> Dr Keel informed Professor Franklin that the Advisory Committee on the Microbiological Safety of Blood and Tissue for Transplantation had resolved that all reasonable measures had been taken to trace components and recipients in Scotland and that the tracing exercise could stop.

**16.53** As the look-back exercises were coming to an end, constitutional change was implemented, with the Scottish Executive (now the Scottish Government) and Scottish Parliament convened on 1 July 1999. Description of the next stages in the developing knowledge of HCV needs to take account of the changes brought about by devolution. The differing courses of action followed in England, Wales and Scotland were described in the report of a meeting of the All-Party Parliamentary Hepatology Group on 18 November 2008.<sup>77</sup> Professor David Goldberg, Chair of the Action Plan Governance Board, gave evidence on the Hepatitis C Action Plan of the Scottish Government.<sup>78</sup> Phase I of the Plan comprised evidence gathering, which disclosed that an estimated 38,000 people were living with the virus in Scotland, of whom 14,800 had been diagnosed and only 2000 had ever received antiviral treatment. Cases of liver failure were increasing. HCV-related mortality had overtaken HIV mortality in the mid-1990s. Part II of the Plan detailed actions aimed at prevention of infection, diagnosis and treatment and care.

**16.54** The prevalence of HCV infection in the blood donating population in both England and Scotland in the first six to 12 months after the introduction of screening was low, particularly in the case of repeat donors, among whom patients with higher risk factors had already been excluded by other means. Effective heat treatment of PFC coagulation products, which was achieved by the PFC in October 1985 for Haemophilia B patients and in April 1987 for Haemophilia A therapy, made a major contribution to the protection of those patients.<sup>79</sup> However, it transpired that the majority of batches of clotting factor concentrates made from volunteer blood donations before effective heat treatment was introduced were indeed infected and the frequency of transmission was similar following use of English and Scottish NHS and commercial material, as had already been inferred.<sup>80</sup> Screening of donations, from 1 September 1991, provided substantial protection for all recipients of blood, blood components and blood products.<sup>81</sup>

**16.55** Most of the current knowledge of Hepatitis C (discussed in Chapter 13, *Knowledge of Viral Hepatitis Now*) developed after September 1991. With routine screening added to viral inactivation the threat of transmission of HCV infection by transfusion or by blood product therapy was substantially removed. Since then, new cases have been largely confined to needle sharing, mother to child transmission and medical procedures.<sup>82</sup>

<sup>82</sup> *Confronting the silent epidemic: a critical review of hepatitis C management in the UK* [LIT.001.4801] at 4814

Practical implementation of Phase II of the Scottish Action Plan has been discussed in relation to the management of prisoners by the Western General Hospital, Edinburgh.<sup>83</sup> However, Professor Goldberg's view remains generally pessimistic:

Maintaining the current level of response is not an option if we are to interrupt the UK's relentless escalation in serious disease and death caused by hepatitis C. Action Plans without muscle have suboptimal impact. There is no time to lose.<sup>84</sup>

### Perception of the severity of NANB Hepatitis/Hepatitis C

**16.56** Professor Goldberg's comment is a reflection of the contemporary view of HCV infection. In the late 1980s there was a material change in the general perception of the severity of the sequelae of NANB Hepatitis infection. The stages in developing thought have been noted but, in order fully to appreciate the extent of the change, it is appropriate to summarise the main points.

**16.57** From about 1978 doctors had monitored haemophilia patients' ALT levels more or less as a matter of course, but in the UK liver enzyme abnormalities without clinical signs of infection were not thought to be indicative of hepatitis. Probably, during the period 1980–88, there developed a general recognition among haemophilia doctors of the existence of NANB Hepatitis but most would have perceived the disease to have a generally benign prognosis.

**16.58** Histology obtained by conventional biopsy was thought by the middle and later 1980s to be the most reliable way of monitoring the severity of liver disease.<sup>85</sup> Earlier misconceptions, based on the histological changes observed in patients with Hepatitis B infection and which had contributed to the inference that NANB Hepatitis was a disease with a generally benign prognosis, were set aside. It came to be appreciated that it was wrong to suppose that chronic persistent and chronic active hepatitis would follow the same clinical course in Hepatitis C as it does in Hepatitis B.<sup>86</sup> In the mid-1980s views had begun to change towards recognising NANB Hepatitis as a more serious condition: chronic persistent hepatitis in haemophilia patients was not as benign as hitherto supposed.<sup>87</sup>

**16.59** Professor Howard Thomas<sup>88</sup> said that this was when views were changing.<sup>89</sup> His evidence is accepted as a reflection of the state of knowledge among experts at the cutting edge of research and clinical practice; general knowledge would develop more slowly. Two relevant conclusions follow. In the first place, there was no generally accepted view prior to 1985 that NANB Hepatitis had more than the generally benign prognosis described by Professor Sherlock before the 8th edition of her book. Secondly, from publication of the 8th edition in 1989 it was generally understood that NANB Hepatitis infection could be associated with serious disease. The development of generally accepted opinion in the second half of the 1980s is likely to have been subject to individual clinicians' access to, and understanding of, the latest developments in the field. It will not have been uniform and it will be likely to have been patchy until 1989.

<sup>88</sup> Currently Emeritus Professor in Hepatology at Imperial College, London.

<sup>89</sup> Professor Thomas – Day 52, page 146

**16.60** By 1989, Professor Sherlock and others (including Professor Thomas) were engaged in studies, based on biopsy findings, which demonstrated that patients with chronic NANB Hepatitis had disease that covered the whole spectrum of acute and chronic hepatitis, including cirrhosis.<sup>90</sup> Professor Sherlock's view, as expressed in the 8th edition of her textbook in 1989, was changing towards recognition that NANB Hepatitis was a disease with a variable prognosis, ranging from a benign condition with spontaneous biochemical improvement after a few years to a chronic disease associated with cirrhosis in a significant proportion of patients, and hepatic failure and hepatocellular cancer in rare cases.

**16.61** It is a material fact that early forms of treatment with Interferon became available for clinical testing in about 1989, soon after the announcement of the Chiron discoveries.<sup>91</sup> Interferon A was first used in England in 1989 and in Scotland in 1990–91. It would be some years before the grant of a licence and approval for use in England and Wales and before equivalent regulatory approval was given in Scotland, in November 1994. However, with the identification of the virus and the arrival of the first forms of therapy (initially thought to be more effective than events were to prove) there was an incentive to further develop knowledge of the disease.

### Developments since 1991

**16.62** Since effective viral inactivation, the infusion of blood products has not been associated with the transmission of Hepatitis C to any material extent. Largely retrospective research demonstrated that until then the frequency of transmission of HCV by Factor VIII concentrates, as shown by raised ALT levels, was similar in both commercial materials and the products of the UK public service fractionators.<sup>92</sup> More generally, transfusion of blood and blood components has not been associated with transmission of Hepatitis C since 1991 when screening of donated blood for HCV became universal practice in the UK. These events superseded the debate which had persisted between 1970 and 1990, as to whether volunteer blood donations were safer than those derived from paid donors, in particular blood products imported from the USA.

**16.63** Current known cases of infection among NHS patients, and cases yet to be diagnosed, generally have their origins in treatment before those critical dates. Unless the infection is picked up incidentally during health screening or following detection of abnormal liver biochemistry in a blood test taken for an unrelated reason, and because the clinical course of NANB Hepatitis/HCV infection is asymptomatic in most cases, the infection may not come to medical attention for many years until late-stage disease is reached. At that stage the patient presents with signs of chronic liver disease or a complication of cirrhosis, such as variceal haemorrhage, ascites or the development of hepatocellular carcinoma. Estimates of undiagnosed cases cannot be substantiated. An unknown number of individuals may currently be infected but remain asymptomatic. Some may be destined never to develop complications; others will progress. Knowledge of the cohort currently infected, and their prognoses, is necessarily incomplete.

**16.64** Professor Thomas emphasised that doubt remained about the progression of the disease generally:

<sup>90</sup> Bamber et al, 'Clinical and histological features of a group of patients with sporadic non-A non-B hepatitis', *Journal of Clinical Pathology*, 1981; 34:1175–80 [LIT.001.0759]

<sup>91</sup> Professor Thomas – Day 53, page 40

<sup>92</sup> Professor Thomas – Day 52, page 76; Professor Thomas' report [PEN.017.1071] at 1077. And see, for example, Yee et al, 'The natural history of HCV in a cohort of haemophilic patients infected between 1961 and 1985', *Gut*, 2000; 47:845–851; [LIT.001.4318]

[S]ome would say, even now, we do not really know the factors that determine the rate of progression and, for instance, in Italy Hepatitis C has a much worse prognosis to what you see in northern Europe ... and ... that's arguably related to all the other factors ... how much alcohol you take, the genetic factors, whether there is co-infection with other viruses, all manner of things.

So I don't think this uncertainty about the natural history that was prevalent between 1978 and 1985 has changed massively. I think we are still wondering: is it 20 per cent or 40 per cent that will develop cirrhosis? All we can deduce from these studies is that some people in the context of normal life ... where we eat and drink ... some people have severe liver disease. But how many, that's an open question still because none of the studies ... are statistically significant. There isn't a large enough sample of unselected cases.<sup>93</sup>

**16.65** There have, however, been advances in knowledge of HCV infection, as shown in Chapter 13, *Knowledge of Viral Hepatitis Now*. Developments since about 1997 have involved laboratory research, by Dr Graeme Alexander and others, on the effect of ageing (measuring people's biological age)<sup>94</sup> and outcome for patients. 'Telomeres', pieces on the ends of DNA which act a bit like the piece of plastic on the end of a shoelace, prevent the DNA from 'fraying' and being damaged. There is a relationship between progressive degradation of DNA, as the telomeres shorten with age, and the development of age-related diseases such as cancer, cardiovascular disease and strokes. It is now known that the same mechanism affects HCV-positive patients, once they reach a certain biological age. They become unable to mount an immune response to infection. The immune system begins to be impaired at around age 60 and cannot cope with Hepatitis C as the virus takes a stronger grip.<sup>95</sup>

**16.66** On the basis of the evidence as a whole on this topic, one would anticipate that a person, infected with HCV after attaining an age at which deterioration in the structure of DNA had progressed sufficiently to damage the DNA's capacity to defend itself against disease, will progress relatively rapidly from infection to cirrhosis and then to liver failure. The 'biological age' of an individual is likely to vary, and Dr Alexander's reference to age 60 might be unduly alarmist in many cases. After that age, however, the epidemiological evidence appears to be clear.

**16.67** In epidemiological terms, Hepatitis C is known to have affected people to some extent in the mid-20th century. However, there is now scientific evidence that it affected the general population in many parts of the world long before that.<sup>96</sup> Since the mid-1980s there has been intensive research into its history and genetics. Research into the genetics of HCV by Professor Peter Simmonds of Edinburgh University has developed methods of classifying sub-types of the virus and effectively constructing an evolutionary tree for the virus showing how the various genotypes and sub-types now recognised have developed and diverged over time. His research has now demonstrated that HCV is a member of a very ancient group of viruses.<sup>97</sup> The characteristics of the disease caused by this virus were, however, quite unknown until the end of the twentieth century.

<sup>93</sup> Professor Thomas – Day 52, pages 138–139

<sup>94</sup> 'Biological age' is a measure of how well or poorly a given individual's body is functioning relative to their calendar ('chronological') age. It measures how old a person's body is compared to what we would expect from an 'average' body at that age.

<sup>95</sup> Dr Alexander – Day 4, pages 42–44 and 46–47

<sup>96</sup> Professor Goldberg – Day 6, page 96

<sup>97</sup> Dr Gillon – Day 6, page 20

**16.68** At the beginning of the oral hearings of this Inquiry in March 2011, the isolation and culture of one type of the complete Hepatitis C virus had been reported.<sup>98</sup> The position in 2011 was explained by Professor Willem van Aken when he gave evidence.<sup>99</sup> Almost 100% of the genomic composition of the virus had been identified by the end of the 1980s but the virus as a whole had not been isolated. It could not be reproduced by culturing (growing in appropriate nutrient substances) and one could therefore not add a known quantum of virus to plasma and submit it to inactivation to see how much virus was destroyed. However, knowledge of almost the whole genomic composition of HCV enabled scientists to make comparisons with other viruses and to select viruses with similar genomic characteristics, such as pestiviruses and togaviruses. These could be used as 'indicator viruses' or proxies for HCV. Knowledge of the genomic composition of HCV sufficient for this purpose was not achieved until around 2000. Reports of the isolation of specific sub-types of particular genomes have been published in the last ten years and there have been significant developments in the treatment of HCV infection as a result.<sup>100</sup>

### Summary

**16.69** The state of knowledge of HCV, and the natural history of the disease, discussed in Chapter 13, *Knowledge of Viral Hepatitis Now*, had not reached maturity in the early 1990s. Professor Thomas' evidence relating to the scientific basis of Chiron's discoveries reflected the results of continuing research over many years.

**16.70** It can be concluded, however, that:

- There was no generally accepted view prior to 1985 that NANB Hepatitis had other than a generally benign prognosis.
- 1985 was a turning point: this was when information began to emerge that would lead to changing views.<sup>101</sup>
- From 1985 it became increasingly understood that NANB Hepatitis infection could be associated with serious disease, progressing to cirrhosis in a significant proportion of cases, and to liver failure and ultimately hepatocellular cancer, albeit rarely.
- The introduction of Interferon therapy from 1989 provided a focus for wider understanding of the characteristics and natural history of HCV infection.
- The science of genetics has been fundamental to the discovery of characteristics of HCV.
- Diagnostic techniques, using model viruses based on genetic analysis, became available at the end of the twentieth and the beginning of the twenty-first century.

**16.71** The current understanding of Hepatitis C is necessary background to a proper appreciation of the accounts of patients and witnesses of experiences of infection with the virus. Depending on the route of transmission, recipients of blood and blood component transfusions are highly likely to have been infected before September 1991 and haemophilia patients to have been infected before October 1984 (patients treated with Factor IX) or April 1987 (patients treated with Factor VIII).

## CHAPTER 17

### BLOOD AND BLOOD PRODUCTS MANAGEMENT

**17.1** This part of the report deals generally with questions related to the collection of blood and its adaptation for clinical use. Some information about the administrative and management structures set up for the provision of blood services in Scotland is required, as background to that discussion, to introduce relevant bodies and to provide an indication of the scope of their responsibilities. It is not necessary for the purposes of the Inquiry, however, to attempt to provide a comprehensive account of the history of these bodies or their legal background. For the early stages in the history the Inquiry has drawn on two monographs describing the organisation of blood collection and management: Dr W N Boog Watson's *The Scottish National Blood Transfusion Association 1940 – 1965*<sup>1</sup> and Professor Ronald Girdwood's *Fifty Years of an Organised Blood Transfusion Service in Scotland*<sup>2</sup> written in the early 1990s. Together these provide fascinating insights into aspects of the story which cannot be developed in this report.

#### **Early history of blood organisation: the SNBTA**

**17.2** The Scottish National Blood Transfusion Association (SNBTA) was formally constituted on 5 March 1940. The need for a national organisation had been advocated by the Blood Transfusion Sub-Committee of the Department of Health's Scientific Advisory Committee, which had been set up at the beginning of 1939 as part of a review of emergency medical preparations in Scotland in anticipation of war following the Munich crisis in 1938.<sup>3</sup>

**17.3** The remit of the Blood Transfusion Sub-Committee had included review of existing facilities and the consideration of necessary changes in securing the provision of blood for emergency use. More particularly the Sub-Committee was instructed 'to advise on the storage of blood in selected centres'. The practice of storing blood in blood banks was novel. It had started in Madrid in 1937 during the Spanish Civil War. Spanish experience influenced the sub-committee and led to a preliminary recommendation, before publication of its report, that stores of blood should be established in the principal population centres. By 3 September 1939, when war was declared, small blood banks had been established at the Royal Infirmary of Edinburgh (RIE) and Stobhill Hospital, Glasgow.<sup>4</sup>

**17.4** The start of the war coincided with other changes in blood transfusion that pointed to a need for central administration of the service. Professor Girdwood recalled:

[T]he situation was that there was a major war in progress just at the time when knowledge about blood transfusion problems and techniques was increasing and clearly some form of Scottish national organization was speedily required.<sup>5</sup>

<sup>5</sup> Girdwood, RH. *Fifty Years of an Organised Blood Transfusion Service in Scotland* (undated) [SNB.010.1836] at 1838

**17.5** Donor centres had already been set up in Edinburgh and Glasgow. The Edinburgh operation had started in 1929 and had grown over the intervening period as a result of a number of initiatives, the last of which, in 1936, had been promoted by the Lord Provost. In Glasgow, the Lord Provost convened a meeting in June 1939 which led to the organisation of a panel of donors and, shortly thereafter, to the establishment of a regional donor centre. In other areas practice was less developed. Following on the sub-committee's report, letters were sent to the Lords Provost and civic leaders throughout the country urging the development of transfusion services. Against the background of enthusiastic but varying response, it was decided that a national council was required to take central control and form a more permanent Blood Transfusion Association. On 9 February 1940, the Department of Health for Scotland invited Lord Rosebery to chair the national organisation in Scotland.<sup>6</sup>

**17.6** From the outset it was intended that the transfusion service would remain a voluntary service, supported by voluntary donations, but it was anticipated that generous central government grants would be required to support the range and scope of services the Association would be expected to provide. During the war, the service was enthusiastically supported by members of the public, both as donors and in raising funds by collections, fairs and other events. That changed after the war. Dependence on the Exchequer grant grew rapidly, to the extent that by 1952 voluntary donations accounted for less than 0.5% of the SNBTA's revenue.

### **A step change in service provision**

**17.7** Over the war period there were major changes in the scope of the blood transfusion service. The SNBTA took over a miscellany of local services including the blood banks in Edinburgh and Glasgow, and small lists of donors in other areas. It also set about establishing some common policies. Five regional centres were established at Dundee, Edinburgh, Glasgow, Aberdeen and Inverness.

**17.8** The introduction of blood banks was a major development. Until 1939 some districts had no storage facilities at all. In some smaller hospital areas relatives were called in when a transfusion was required and, subject to compatibility, were bled immediately before treatment of the patient. Some hospitals had lists of professional donors who would give blood for a fee. Some favoured voluntary donation, recruiting donors by public appeal or with the help of charitable organisations.<sup>7</sup> The SNBTA developed new procedures for the organisation of blood collection and new facilities for handling and processing the blood collected. In the future, only exceptionally would a volunteer be called on to provide blood for a single patient. Donor sessions would be organised and blood collected to build up and replenish blood banks. Blood banks would store whole blood or plasma to be called down by hospitals in the region for clinical use. Storage required refrigeration equipment and support services. Funds were required immediately and were raised with such efficiency that by July 1940, the chairman of the SNBTA technical committee could claim that the various services could cope with any demands which might be made on their resources.<sup>8</sup>

<sup>6</sup> Boog Watson, WN. *The Scottish National Blood Transfusion Association, 1940–1965*, 1965, E&S Livingstone Ltd, Edinburgh and London [PEN.019.1359] at 1364–5

<sup>7</sup> Ibid [PEN.019.1359] at 1365

<sup>8</sup> Ibid [PEN.019.1359] at 1366

**17.9** However, technological changes were imminent. It became clear that plasma had considerable value since it obviated the need for cross-matching in an emergency situation, and was particularly effective in treating shock. There was a considerable demand from the armed forces. Unrefrigerated plasma was shipped from the United States (before the USA entered the war), but often arrived with bacterial contamination. Casualties in the war brought home the need for local supplies to be available.<sup>9</sup> In August 1941, central depots were organised in Edinburgh and Glasgow, to prepare raw material collected locally and from other regions of Scotland and to store plasma for use. This removed the risk of contamination associated with imported plasma. It was agreed that a predetermined quantity of blood for processing would be regularly provided from each blood bank in the country.<sup>10</sup>

**17.10** It was then shown in England that plasma could be dried and reconstituted. In its dried state plasma could be preserved for a much longer period. There arose a great demand for the product, especially from the armed forces, but also for emergency use in civilian practice.<sup>11</sup> A unit for the production of dried plasma was required. The necessary apparatus was installed in Edinburgh at the beginning of 1943 to meet all Scottish needs. Edinburgh was thought to be in less danger of bombing than the west of Scotland. For the next 12 years, it continued to be the processing centre for the whole of Scotland for the production of dried plasma.<sup>12</sup>

**17.11** In the meantime, in the early months of the war, the Department of Health (DoH) funded the provision of a 'saline infusion fluids centre' for the preparation of saline glucose and other solutions used for intravenous injection. It had been located in Glasgow where the clinician selected by the Department to take charge of the operation worked. These early decisions were reflected in the location of the major laboratory and production facilities in the Glasgow and Edinburgh regions as they developed. The laboratory at Edinburgh was expanded to handle the fractionation of plasma when that process was introduced in 1952, initially for the production of immunoglobulin.<sup>13</sup> As demand grew for the specialist services provided in Glasgow, civil defence considerations led to the relocation of its facilities to Law Hospital, Carluke. The western service became responsible for plasma drying in 1956 for the whole of Scotland except the Edinburgh and south-east region.<sup>14</sup> The provision of laboratory and other facilities required for the development of the service is discussed in Chapter 19, *Production of Blood Products – Facilities*.

**17.12** The war years saw huge changes in the transfusion service, in its organisation and in its facilities and, more particularly, in the scope and range of the blood and blood components it managed and provided. There were also changes in the relationships between the service and its donors.

## Donor organisation

**17.13** Before March 1940, donor organisation was a strictly local concern and policies varied across the country. Small payments and other forms of reward had been made to donors in some areas of Scotland. The newly formed SNBTA favoured the use of voluntary donations and decided to bring an end to payments. This was one of the first acts of the new body and helped to bring about consistency in the practice of recruiting and dealing with donors throughout Scotland. It came to characterise the Scottish system in popular perception and in the representations made about the system domestically and internationally. In *The Gift Relationship*,<sup>15</sup> published in 1970, Richard Titmuss, a United Kingdom social scientist, described the British system of blood management as following the social welfare model, with blood treated as a free community resource, collected and distributed by the State. In Scotland the State provided financial support, but did not have a significant managerial role before the National Health Service was established on 5 July 1948, when the National Health Service (Scotland) Act 1947 (the 1947 Act) came into force.<sup>16</sup>

**17.14** The SNBTA took over a service that had grown in a piecemeal fashion. Operational units had a strong sense of local identity. The SNBTA developed a network of blood transfusion centres and panels of volunteer blood donors, in the modern sense, that reflected practice throughout the United Kingdom after the Second World War.<sup>17</sup> In general, however, Titmuss's characterisation applied to Scotland from 1940: the developing service conformed to the social welfare model.

**17.15** From 1940, the service continued to be based on the voluntary donor. War conditions affected the operation of the service. Many potential donors were on active service in the armed forces. Others were employed in occupations remote from collection centres. Mobile collection teams were necessary in some areas to meet the growing demand for blood in 1943 and 1944. There was a strong public response. In 1943 the number of donors rose from 43,000 to 57,000 and in the first half of 1944, as 'D-Day' approached, a further 10,000 donors were recruited. The invasion of France created increased demand in the third quarter of 1944. However, after the war the transition to peace was difficult. Staff changes followed the return of personnel to civilian life. Premises had to be returned to civilian use. Public enthusiasm waned and donor attendances at sessions fell.<sup>18</sup>

**17.16** The wider environment had changed with peace. The requirements of hospitals treating service personnel decreased after the war. However, changes in the therapeutic application of blood and blood components and products in civilian hospitals continued to increase with the growing importance of the use of blood in maternity work and in the treatment of burns and other accident damage. Transfusion was no longer a near-desperate measure in the face of emergency: it had become a well-established form of treatment with ever widening possibilities. The incentive to support the service financially by private donation had changed. In the meantime, the work of the SNBTA was made more difficult by uncertainty about its future. It was increasingly dependent on public funding and, as a corollary, exposed to the influence of government policy. There was a

<sup>15</sup> Titmuss, RM. *The Gift Relationship: From Human Blood to Social Policy*. 1970, Allen & Unwin, London

<sup>16</sup> The voluntary principle is discussed more fully in Chapter 18, *Collection of Blood – General*, paragraphs 18.3 to 18.20.

<sup>17</sup> Dr Derek Norfolk – Day 7, page 60

<sup>18</sup> Boog Watson, WN. *The Scottish National Blood Transfusion Association, 1940–1965*, 1965, E&S Livingstone Ltd, Edinburgh and London [PEN.019.1359] at 1367–8

possibility in 1948 that the Association would be merged with the National Health Service. That did not happen.

**17.17** The Association's property and staff were transferred to the Secretary of State when the National Health Service was established but the SNBTA itself continued as an independent body.<sup>19</sup> A proportion of the officers and members of the Association were now nominated by the Secretary of State or by regional hospital boards. But the regime established by agreement with the Secretary of State provided the stability the Association required to get on with its work. An early task was revision of the lists of donors in every region to reduce the registered donors to those who were 'live', who could be expected to attend donor sessions when asked to do so. The work of recruiting new 'live' donors was vigorously pursued.<sup>20</sup>

**17.18** The need for review of the donor system varied across the individual regions. Before the war, Edinburgh was the only place in Scotland with an established blood transfusion service. In other places some hospitals had worked with small lists of donors. The drive to recruit more donors had been managed in various ways across Scotland. In certain areas the population was concentrated around major settlements, while in others the scattered population led to a greater reliance on mobile teams that often had to travel considerable distances. The western service, based round Glasgow, had been able to recruit many donors from the work forces of large industrial employers. An early task for the SNBTA had been to establish a suitable network of blood banks, taking account in some regions of the need to equip smaller, more remote, hospitals that could not easily be served by the larger regional centres.

**17.19** The heterogeneity of the regions was largely a reflection of geography, population spread and employment. This did not change after the war, nor with the establishment of the National Health Service. Blood collection had to take account of the realities. Regional organisers, appointed in each region in 1940 with responsibility for raising the money required to maintain the service, to recruit donors and to arrange blood donation sessions, depended for success on voluntary local organisers. Dr Boog Watson said:

In every rural parish, country town and city district in which donors were recruited the regional organisers by personal search and personal approach secured their local organisers, often through such channels as the Red Cross, W.V.S., or Women's Rural Institutes.<sup>21</sup>

This produced a diverse group of men and women from all walks of life who maintained contact with donors. The collection of blood had the character of a voluntary charitable activity. Effective organisation depended on the goodwill of the organisers and the donors and their personal commitment. These characteristics would continue.

### **The role of ministers**

**17.20** The National Health Service (Scotland) Act 1947 provided that it would be a function of the Secretary of State to promote the establishment of a comprehensive health service and provide or secure the provision of services, which necessarily included the provision of blood for clinical use. Accordingly:

<sup>19</sup> Ibid [PEN.019.1359] at 1368

<sup>20</sup> Ibid [PEN.019.1359] at 1369

<sup>21</sup> Ibid [PEN.019.1359] at 1377-8

- From 1948, the principal duty of providing effective health care in Scotland, including promoting the effective provision of blood transfusion services, has been the responsibility of the Secretary of State for Scotland and now the Scottish Ministers.
- The Secretary of State assisted by Scottish Office Health Ministers, and now Scottish Ministers and in particular the Health Ministers, supported by their respective civil servants, have operational control of health care policy.

**17.21** Central government provided increasing funding of the SNBTA's operations by Exchequer grant. The sum provided in 1944 was £7250. By 1964 that had risen to £363,368.<sup>22</sup> There was ever-increasing need for funding of the service, including the funding of major capital projects. These included facilities for the production of coagulation factor products for the treatment of haemophilia and other coagulation disorders. It was probably inevitable that the SNBTA's role would be reduced.

**17.22** Professor Girdwood commented:

When the war ended the need for Government financing became much greater and the coming of the National Health Service necessitated a complete reconsideration of the organization of blood transfusion services in Scotland. It was decided not to make this a responsibility of Regional Hospital Boards .... The notion that the Association could continue to administer the Service was not realistic ....<sup>23</sup>

However, change did not come as quickly as it might. Legislation was not in place until 1972.

**17.23** Section 19 of the National Health Service (Scotland) Act 1972 provided for the constitution of the Common Services Agency for the Scottish Health Service (the CSA) with effect from 1 April 1974.<sup>24</sup> It provided that:

(2) The Secretary of State may by order delegate to the Agency such of his functions as he considers appropriate.

And

(8) In carrying out its functions the Agency shall act subject to and in accordance with such directions as may be given by the Secretary of State.

## The CSA

**17.24** The functions of the CSA were initially set out in the National Health Service (Functions of the Common Services Agency) (Scotland) Order 1974<sup>25</sup>. Article 3 of the Order, as regards blood, provided:

<sup>22</sup> Ibid [PEN.019.1359] at 1381

<sup>23</sup> Girdwood, RH. *Fifty Years of an Organised Blood Transfusion Service in Scotland* (undated) [SNB.010.1836] at 1843

<sup>24</sup> National Health Service (Scotland) Act 1972 s 19(3) and National Health Service (Functions of Common Services Agency) (Scotland) Order 1974 (SI 1974/467) Article 3(a). From 28 May 2004 the CSA adopted the name 'NHS National Services Scotland': <http://www.nhsns.org/uploads/publications/AnnualReportandAccounts0304-for%20website.pdf>. This change had no legal effect and the statutory name is used in this Report.

<sup>25</sup> SI 1974/467

It shall be the duty of the Agency to undertake the following functions:—

....

(e) the provision of supplies of human blood for the purposes of carrying out blood transfusion and related services, including the production of blood fractions.

Formally, the CSA took over most of the functions of the SNBTA in 1974. In structural terms, the CSA operated through a management committee and a series of sub-committees including, in time, the (CSA) Blood Transfusion Sub-Committee.

**17.25** Accordingly, in terms of the successive Health Acts and subordinate legislation:

- From 1974, the CSA had delegated responsibility for the operational management of blood services.
- The CSA was subject to, and was obliged to act in accordance with, such directions as might be given by the Secretary of State.

**17.26** The 1947 Act was repealed by the National Health Service (Scotland) Act 1978 (the 1978 Act) which continued the general duties of the Secretary of State, including the provision or securing the provision of services. The CSA was reconstituted under the 1978 Act and section 19 of that Act repeated the provisions of section 19 of the 1972 Act as quoted above. Under the 1972 and 1978 Acts the members of the Management Committee of the CSA were appointed by the Secretary of State.

**17.27** That remained the position until, with effect from 1 October 2008, the 1974 Order was revoked by the National Health Service (Functions of the Common Services Agency) (Scotland) Order 2008.<sup>26</sup> So far as relevant for present purposes, the 2008 Order removed the production of blood fractions from the functions of the CSA, but continued to provide for delegation of the provision of supplies of human blood for transfusion and related services.

### **The CSA and the Blood Transfusion Service**

**17.28** Scottish Home and Health Department (SHHD) circular HSR(72)C2<sup>27</sup> which dealt specifically with the CSA, narrated under the heading 'Functions' that the purpose of the new organisation was to provide the SHHD and the Health Boards with a variety of services which could be provided most efficiently by a single agency. It also stated, under the heading 'Central Organisation' that:

The main responsibility for the day to day running of each service within the allocated expenditure and in accordance with broad policies will fall to the chief officer or director of that division of the CSA; and he will in most cases be directly responsible to the Management Committee or to any sub-committee which may be set up for the particular service. It is unlikely that the Management Committee as such will normally have to concern itself with the detailed running of any of the services provided by its operational divisions or that it could attempt to do so over a wide range of services.

<sup>26</sup> SSI 2008/312

<sup>27</sup> SHHD circular HSR(72)C2, *Common Services Agency*, 3 November 1972 [PEN.019.1477]

....

As indicated, regulations made by the Secretary of State may provide, where appropriate, for sub-committees which include persons not members of the Management Committee. It will be open to the Management Committee to propose such sub-committees for those services where it seems necessary to do so....<sup>28</sup>

**17.29** The government's intention to transfer responsibility for the Blood Transfusion Service to the CSA was set out in the Scottish Home and Health Department (SHHD) circular HSR(73)C40. It stated under the heading 'Reorganisation';

On the appointed day, the Blood Transfusion Service will become a division of the CSA; operational arrangements, based on the five centres and the Protein Fractionation Centre will not be affected. Staff employed by the Association will transfer to the employment of the CSA, although this will not affect the work or organisation of the centres.<sup>29</sup>

**17.30** That operational control was intended to remain with the SNBTS was recognised by the CSA Management Committee as reflected in an extract from the minutes of its second meeting on 14 March 1974:

It was noted that the operational responsibility for the Blood Transfusion Service would rest with each Regional Director within his region. So far as operational problems affecting Scotland as a whole were concerned it was agreed that a Co-ordinating group should be set up consisting of the National Medical Director, the five Regional Directors, the Scientific Director of the Protein Fractionation Unit, and the Administrative Officer. The National Medical Director would act as spokesman for the group to the Management Committee.

**17.31** SHHD circular HSR(73)C40 was greeted with concern among transfusion specialists. They were worried that the CSA would lack the technical competence to manage the highly specialised transfusion service that was envisaged as the replacement for the SNBTA and that the Regional Directors would lose the autonomy they had enjoyed under the SNBTA.

**17.32** These concerns were expressed by a member of the South-East Scotland Regional Blood Transfusion Service (probably Dr Robert Cumming),<sup>30</sup> in a paper circulated on 29 November 1973 commenting on the circular. His concern was that circular HSR(73)C40 lacked information about future arrangements. It did not show 'evidence of policy', nor did it make adequate provision for 'representation by those who best understand the clinical, scientific and technical complexities of blood transfusion practice'.<sup>31</sup>

**17.33** From a different point of view, Mr John Watt, Scientific Director of the Protein Fractionation Centre (PFC), sent proposals for restructuring the service to all Regional Transfusion Directors in December 1973.<sup>32</sup> He proposed a centralised management arrangement, which he argued would be compatible with the new overall organisation, but would operate through a committee comprising administrators, transfusion and

<sup>28</sup> Ibid [PEN.019.1477] at 1478

<sup>29</sup> SHHD circular HSR(73)C40, *Common Services Agency – The Blood Transfusion Service*, 26 October 1973 [SNB.011.0587]

<sup>30</sup> Dr Cumming was at the time Regional Director of the SNBTS (Edinburgh and South-East Scotland Region), but about to retire. See his letter of the same date to Dr Wallace and others [SNB.011.0589]

<sup>31</sup> *The Blood Transfusion Service: Common Services Agency – (HSR(73)C40)* [SNB.011.0592] at 0592–3

<sup>32</sup> *The Scottish National Blood Transfusion Service: A Future in the Common Services Agency?* [SNB.011.0602]

scientific directors, donor representatives, and representatives of user interests. The bias in his proposals was towards management by experts and those intimately concerned with the quality of delivery.

**17.34** Writing on the eve of the restructuring of the Blood Transfusion Service in January 1974, Dr John Wallace, Glasgow and West of Scotland BTS, said:

S.N.B.T.A., apart from its financial control, has allowed each regional director comparative freedom in developing the transfusion service within his region. I am now afraid that we are likely to feel the iron hand of central management, unless we exert professional influence.<sup>33</sup>

Dr Wallace was concerned that integration would undermine community health at local level, in view of the wide diversity of the service requirements within individual regions.

**17.35** Differences of approach among the Directors were resolved early in 1974. On 16 January the Regional Transfusion Directors and Mr Watt wrote to the secretary of the SNBTA commenting on the restructuring of the service.<sup>34</sup> They repeated concern about the information in circular HSR(73)C40. They drew attention to the far-reaching changes taking place in the clinical, scientific, technical and organisational spheres of blood transfusion practice; proposed that the arrangements for the transfer to CSA be held in abeyance; and argued that SNBTA should continue in office pending an acceptable solution for the effective management of the Blood Transfusion Service. They asked for more time to be given to the development of proposals, and for discussion.

**17.36** Meetings followed that letter,<sup>35</sup> but the government's policies were implemented against the opposition of the Directors. It was an inauspicious start to new arrangements intended to provide an integrated service. Some practical steps were taken. The service had been transferred. A National Medical Director had been appointed.

**17.37** Even after the establishment of the CSA and the SNBTS, Transfusion Directors continued to be exercised by the lack of transfusion expertise on the CSA's Management Committee and to press for alternative arrangements. During the later part of 1976 the Directors were in touch with Dr McIntyre, SHHD.<sup>36</sup> They reiterated their initial anxiety and stated:

The anxiety... has been realised. The Management Committee does not have within, or available to, it, such independent specialist and other advice as was available within its predecessor, the Executive Committee of SNBTA. This lack of professional expertise and clinical user involvement is considered by the Transfusion Directors to be a retrograde step in the management of the service.<sup>37</sup>

They proposed the transfer of the management of the Blood Transfusion Service to a management committee, independent of the CSA and directly responsible to the Secretary of State, with a wide representative membership including transfusion specialists, donor interests and user interests.<sup>38</sup>

<sup>33</sup> Letter to Dr Charles Cameron dated 4 January 1974 [SNB.011.0596] at 0598–9

<sup>34</sup> Letter [SNB.011.0610]

<sup>35</sup> See *Future Management of the Blood Transfusion Service in Scotland* [SGH.001.2758] at 2759

<sup>36</sup> Letter of 22 October 1976 from Miss Corrie to Dr McIntyre [SGH.001.2758]; Letter of 15 November 1976 from Dr Wallace to Dr McIntyre [SGH.001.2738]

<sup>38</sup> *Ibid* [SGH.001.2758] at 2760

**17.38** Regional Directors continued to be apprehensive that the centralised management arrangements of the CSA were in conflict with what they understood to be the 'responsibilities and authorities' of their roles.<sup>39</sup>

**17.39** The Directors' proposals and representations were given short shrift in a reply by Dr McIntyre dated 2 December 1976. He wrote:

It is only fair to say ... that the SNBTS is now formally a part of the NHS and can therefore only be administered in the existing health service framework. On a number of occasions General Jeffrey<sup>40</sup> raised with officers of the Department the question of the SNBTS being taken outside the framework of the CSA and on each occasion it was made quite clear that there would be no question of this.<sup>41</sup>

General Jeffrey was formerly Chairman of the SNBTA, and was appointed the first National Medical Director of the SNBTS in 1975. He served in that post until his death in 1977. Dr Cash was appointed to replace General Jeffrey in October 1979.

**17.40** Dr McIntyre's letter was not the end of the matter. The Regional Directors had understood that there might be a review of management after three years. A meeting of Regional Directors and the SHHD took place on 18 May 1977 at which there appears to have been a frank exchange of irreconcilable views.<sup>42</sup> Leaving aside personal comments, there were two complaints: the CSA management structure was costly, inefficient and counter-productive; and there was a lack of professional expertise on or available to the CSA committees which had responsibility for the management of the Blood Transfusion Service. The Inquiry has not investigated and cannot form or express views on the detailed complaints and comments made on behalf of the Directors, principally by Professor John Cash. It is sufficient to note that they were extensive, and appeared to reflect the apprehensions the Directors had expressed in 1974, and were further reflected in a loss of harmony, and acute disquiet. From the Directors' point of view, there appeared to be no progress.

**17.41** On 15 June 1977, however, a step was taken towards establishing a framework for managing the service. The CSA Management Committee agreed to establish an ad hoc committee, 'to examine and report to the Management Committee on the management arrangements for the Blood Transfusion Service within the Common Services Agency'. The ad hoc committee in turn set up a working party in which representatives of the SNBTS Directors participated.<sup>43</sup>

**17.42** On 20 December 1977, Professor Cash reported to the SNBTS Directors Co-ordinating Group that the CSA Management Committee had proposed a remit for a blood transfusion sub-committee of the Management Committee. He reported:

This met most of the aims which the Directors had sought in their meetings before the Working Party began and the Director representatives hoped that further progress would be made.<sup>44</sup>

The Working Party met and made proposals to the ad hoc committee.

---

<sup>39</sup> Dr McClelland's statement on collection of blood from 'higher risk' donors [WIT.003.0072] at 0073

<sup>40</sup> Former Chairman of SNBTA

<sup>41</sup> Dr McIntyre's letter [SNB.003.4499]

<sup>42</sup> Note of meeting [SGH.001.2587]

<sup>43</sup> Minute of meeting of CSA Management Committee, 26 April 1978 [PEN.012.1745]

<sup>44</sup> Minutes of SNBTS Co-ordinating Group, 20 December 1977 [SNB.003.4712] at 4715

**17.43** Thereafter a draft report of the ad hoc committee's proposals was circulated and reported to the Co-ordinating Group on 14 March 1978. At this stage, there was concern that the proposals departed in some respects from the Working Party's report to the ad hoc committee. Among representations agreed to be made on the proposals, the following were material:

- The National Medical Director should be a non-voting member of the proposed blood transfusion sub-committee.
- Transfusion Directors should receive sub-committee papers and have the right to attend if they wished.
- The National Medical Director was to receive the agenda for meetings of the Management Committee and its sub-committees.
- The National Medical Director should be able to nominate a deputy to attend meetings of the proposed sub-committee.<sup>45</sup>

**17.44** After further discussion, the ad hoc committee reported its recommendations that a sub-committee of the Management Committee should be set up specifically to deal with Blood Transfusion Service matters with specified terms of reference. These recommendations were accepted by the Management Committee on 26 April 1978. The Regional Directors also accepted the recommendations.<sup>46</sup>

**17.45** The terms of reference of the CSA Blood Transfusion Service Sub-Committee defined as at July 1978 included:

(1) The review of the operational activity of the Blood Transfusion Service to ensure that the services provided are efficient and economic and within approved financial allocations.

(2) The formulation of proposals for the development and improvement on the services given by the Blood Transfusion Service and to make recommendations of the priority and proposed programming of such developments and improvements.

(3) Liaison with other authorities on developments in the Blood Transfusion Service and on operational matters.

....

(8) The provision of medical and operational equipment required for the efficient and economic operation of the Blood Transfusion Service.

(9) The preparation of a capital programme (including accommodation and vehicles) for the Blood Transfusion Service...

....

(10) The appointment of such ad hoc advisory committees and working parties as may be necessary to advise on specific matters relating to the services provided by the Blood Transfusion Service.

---

<sup>45</sup> Minutes of SNBTS Co-ordinating Group, 14 March 1978 [SNB.003.4753] at 4754-5

<sup>46</sup> Minutes of CSA Management Committee special meeting on 26 April 1978 [PEN.012.1745]

(11) Any other matters relating to the Blood Transfusion Service which the Management Committee [of the CSA] may refer from time to time.<sup>47</sup>

In formal structural terms there was significant delegation to the sub-committee of the functions listed, and this would continue to be the case.

**17.46** The membership of the sub-committee was specified. The Management Committee was to be represented by six members. In addition there were to be two specialists in clinical medicine, two specialists in laboratory medicine, one SHHD medical officer, and one representative of donor interests. The National Medical Director was not to be a member of the sub-committee. It was provided that that officer should receive the agenda and all papers for each meeting of the sub-committee and be entitled to attend or be represented at meetings. Other Transfusion Directors might attend with the agreement of the Convenor. Three of the four representations listed in paragraph 17.43 above were met.

**17.47** The terms of reference of the sub-committee delegated control of the establishment, appointment and dismissal of staff, with the following exceptions: the National Medical Director and Regional Directors, the Scientific Director of the Protein Fractionation Centre, and other consultant medical staff. The National Medical Director was to be responsible to the Management Committee for the efficient operation of the service, including the Protein Fractionation Centre, and, within the resources available to the CSA, for the implementation of national policies with regard to the supply of blood and blood products to the National Health Service.<sup>48</sup> The job description of the National Medical Director agreed on 26 April 1978 outlined the duties and responsibilities of the office, including:

1. Ascertainment of the needs of clinicians for blood products and for ensuring in consultation with the Regional Directors and the Scientific Director of the [PFC] that adequate supplies of plasma are made available and processed accordingly at the [PFC] to meet these needs.
2. Co-ordination of the distribution of supplies of blood products.
- ....
5. Advising the [SHHD] on national policy questions affecting the development of the Blood Transfusion Service.<sup>49</sup>

Various administrative matters also formed part of the job description. There was no definition of any relationship between the National Medical Director and the sub-committee.

**17.48** The constitution of the CSA Blood Transfusion Service sub-committee went a considerable way towards meeting the objections to the lack of expertise available to the Management Committee in relation to blood transfusion matters. However, neither the sub-committee nor the National Medical Director had executive control of the management of the service. By inference, that was left with the Regional Transfusion Directors and the Scientific Director of the PFC. The reasoning of the Management Committee in specifying the role of the National Medical Director was set out in the minutes of the meeting of 26 April 1978, as an aspect of the constitutional arrangements for the sub-committee:

---

<sup>47</sup> Minute of Blood Transfusion Service Sub-Committee meeting, on 19 July 1978 [PEN.012.1751] at 1755

<sup>48</sup> Minutes of CSA Management Committee special meeting, on 26 April 1978 [PEN.012.1745] at 1750

<sup>49</sup> Ibid

[T]o provide the most suitable management structure for maintaining and developing the highest standards within the Blood Transfusion Service, the National Medical Director should be responsible to the Management Committee for the efficient operation of the Blood Transfusion Service in Scotland, including the Protein Fractionation Centre ....<sup>50</sup>

**17.49** The National Medical Director's direct responsibility to the Management Committee for the efficient operation of the service was not qualified by any requirement for reference to the sub-committee. The sub-committee's overview role included review of activities falling within the job description of the National Medical Director, however, as an officer of the Management Committee. Relationships among the several participants in the management structure were poorly defined, from a modern perspective. One element in the job description of the National Medical Director should be noted. It was part of the duties of the office to advise the Scottish Home and Health Department on national policy questions affecting the development of the Blood Transfusion Service, apparently directly and without involving the Management Committee or its sub-committee.

### **CSA oversight of the Blood Transfusion Service: the formal position**

**17.50** The formal arrangements for CSA oversight of the SNBTS that were established in 1978, continued throughout the remainder of the reference period and beyond. In 2002 a review was undertaken of 180 public bodies including 49 NHS bodies, one of which was the CSA. The review of the CSA looked at all aspects of its role, including its management of the SNBTS and the management structures in place.<sup>51</sup> The conclusions of that Review noted general satisfaction with the CSA:

[A]part from SNBTS where stakeholders and staff alike feel relocation of SNBTS to another organisation is preferred.<sup>52</sup>

**17.51** The narrative of the report identified three causes of dissatisfaction, two of which related to strategic planning and finance in 1999, and a third which is of greater relevance for present purposes:

A perception in SNBTS that the performance of the organisation is managed by the Medicines Control Agency, the Clinical Pathology Association and SNBTS Clinical User group, and CSA is not qualified to manage the performance of SNBTS.

**17.52** The report commented that the critical views identified in the course of the review perhaps reflected:

[A]n inadequate understanding of the role of the NHS Boards across Scotland in supporting, developing and holding to account specialist services to ensure they meet the needs of the public. Whatever organisational arrangements apply, there needs to be a proper system of corporate and clinical governance, and

<sup>50</sup> Ibid [PEN.012.1745] at 1747

<sup>52</sup> Scottish Executive, *Public Bodies Review: Review of the Common Services Agency for NHS Scotland*, 2002, at p17, available at <http://www.sehd.scot.nhs.uk/publications/DC20021002csa.pdf> (accessed 8 December 2014)

a Board providing a focus for efficient, effective and accountable governance and strategic leadership and direction.<sup>53</sup>

**17.53** The SNBTS plea for re-organisation, which had been repeated, was dismissed, but it was observed in the conclusions of the Review:

There is some justification for their concerns because of the lack of a developed system of clinical governance in CSA; a lack of clarity about the role and purpose of the Board, and therefore a lack of clarity about how CSA and its component Divisions support and add value to each other's activities.<sup>54</sup>

**17.54** It is not part of the remit of this Inquiry to provide a critique of the management or management structure of the CSA in relation to the SNBTS. It is, however, helpful when looking at the work of the SNBTS during the reference period to understand the views of senior SNBTS staff at the time, given the conclusion of the Review concerning the CSA's lack of a developed system of clinical governance and its failure to establish a clear understanding of its role and purpose in the minds of SNBTS staff and other stakeholders.

**17.55** Whether justified or not, there was a deep-rooted view among transfusion professionals until at least 2002 that the CSA did not make a positive contribution to the delivery of the service.

**17.56** The 2002 Review reflected the reality of (a) the statutory framework governing the NHS, and (b) the importance of public accountability, as factors underlining the existing governance structures. The Scottish Government has submitted that:

While the utility of CSA in the management structure was at some stages questioned, it is important to emphasize that its role was part of the general arrangements under which both special and territorial health boards exercised the principal responsibility for the day to day running of the health service in Scotland. Those arrangements devolved responsibility from SHHD as the central department and distanced the NHS from political interference.<sup>55</sup>

**17.57** For present purposes, it is sufficient to note this view. The Transfusion Directors' concern that the management structure lacked specialist membership and advice necessary for effective clinical governance clearly continued notwithstanding the 1978 changes. The authority of the National Medical Director was less well defined than his responsibilities. Those background factors may throw light on some of the events that will be discussed in this report.

### **CSA oversight of the Blood Transfusion Service: the factual position**

**17.58** The delivery of the service in the 1970s had become challenging. The activities of the SNBTS at or about the beginning of the reference period were described in evidence submitted to the Royal Commission on the National Health Service, in January 1977.<sup>56</sup> In relation to management, the evidence was perhaps aspirational rather than reflective of practical reality. In the 1970s, and perhaps reflecting its limited role, the SNBTS

<sup>53</sup> Scottish Executive, *Public Bodies Review: Review of the Common Services Agency for NHS Scotland*, 2002, at page 7, <http://www.sehd.scot.nhs.uk/publications/DC20021002csa.pdf> (accessed 8 December 2014)

<sup>54</sup> *Ibid* at page 17

<sup>55</sup> Submission to the Inquiry on behalf of the Scottish Government [PEN.019.0274] at 0280

<sup>56</sup> Evidence from the SNBTS to the Royal Commission on the NHS [SNB.003.4592]

headquarters was a tiny organisation comprising the National Medical Director, one national administrator, a secretary and a clerical assistant, with little practical influence over regional operations.<sup>57</sup> But the evidence of the regional services operated from regional transfusion centres provided a clear explanation of the scope of the work done at that period:

The Protein Fractionation Centre is sited in Edinburgh ... It serves the whole of Scotland, and at some future date may serve part of England. Its principal function is the fractionation of human blood plasma supplied by the regional services and the return of finished blood products to them.<sup>58</sup>

The National Headquarters, [responsible for the co-ordination of work within the SNBTS,] is also based in Edinburgh.<sup>59</sup>

The functions of the SNBTS ... the following are carried out by all or some of the regional services, in conjunction with the PFC:

- (a) Donor recruitment and the organisation of blood-collecting sessions.
- (b) Medical selection of blood donors and the collection of blood, either as single donations, or by plasmapheresis.
- (c) Collection of blood from selected donors for the preparation of blood-grouping anti-sera; and the immunisation of animals to provide other laboratory reagents.
- (d) Immunisation of volunteers for the production of anti-D immunoglobulin.
- (e) Tests on each donation to determine its blood groups, and tests for transmissible disease.
- (f) Compatibility testing of donations for transfusion to individual patients.
- (g) Antenatal and neonatal blood group serology in relation to the prevention and treatment of haemolytic disease of the newborn.
- (h) Blood group serological reference services, including the investigation of cross-matching problems and transfusion reactions.
- (i) Leucocyte and platelet typing; compatibility testing for organ transplantation.
- (j) Separation of blood into its cellular elements; and the fractionation of plasma to produce a wide range of therapeutic substances (below).
- (k) Clinical blood transfusion, including the management of haemostatic defects, the use of cell separators, and advice on the use of blood and blood products.
- (l) Research and development, and participation in training programmes for postgraduates, undergraduates, medical laboratory technicians, and nurses.

<sup>57</sup> Dr McClelland – Day 9, page 16; Dr McClelland’s statement on collection of blood from ‘higher risk’ donors – [WIT.003.0072] at 0073–74

<sup>58</sup> Evidence from the SNBTS to the Royal Commission on the NHS [SNB.003.4592]

<sup>59</sup> The BTS HQ was established in 1974 at the time of the transfer to CSA: see *Future Management of the Blood Transfusion Service in Scotland* [SGH.001.2758] at 2759

The products prepared for transfusion include:

Whole blood

Concentrated red cells:

- fresh
- frozen

Platelets

Plasma:

- dried
- fresh dried
- fresh frozen

Albumin solution

Stable plasma protein solution

Normal immunoglobulin

Specific immunoglobulins:

- anti-D
- anti-tetanus
- anti-vaccinia
- anti-hepatitis B
- anti-varicella/zoster
- anti-rubella

Coagulation factors:

- fibrinogen
- factor VIII – as cryoprecipitate (frozen)
  - as 'intermediate factor' (dried)
- factors II, IX, X
- factors II, VII, IX, X<sup>60</sup>

**17.59** This was the range of activities at about the start of the reference period that were, at least nominally, delegated by the Secretary of State to the CSA to manage. It had developed against the background of significant and sometimes dramatic changes in the therapeutic application of blood and blood products, in the scientific and technological developments that enabled their production, and in the facilities provided for research and development and for the manufacture of blood products. That would continue throughout the reference period: scientific and technological change drove changes in the use of blood and in the production and application of blood products.

**17.60** While the management structures put in place by the CSA clearly generated considerable debate, it is reasonably clear that they did not have the significant impact on the autonomy of local transfusion directors that had been feared. Taking over practical responsibility for the wide-ranging activities of the service would have been a major logistical exercise. In the event, notwithstanding the formal structural changes, the Blood Transfusion Service would continue to be characterised by a high degree of local autonomy, until substantial restructuring of the SNBTS on a national functional basis began in the late 1990s, long after the period in which the events of importance in this Inquiry had happened.<sup>61</sup>

<sup>60</sup> Evidence from the SNBTS to the Royal Commission on the NHS [SNB.003.4592] at 4593–5

<sup>61</sup> Professor Turner – Day 7, pages 11–12

**17.61** Before the CSA was established and the management structures described above had been put in place, the SNBTS Regional Directors and the Scientific Director of the PFC had met on a regular basis with representatives of the SHHD to discuss operational matters. The work of the Regional Directors as a group continued after the developments in 1978. In addition, as noted in paragraph 17.47 above, the National Medical Director's role as specified in the job description of 26 April 1978 expressly included advising the SHHD on national policy questions affecting the development of the Blood Transfusion Service.

**17.62** Regional autonomy was maintained among the Regional Directors, In the course of the Inquiry Professor Cash, who was appointed National Medical Director, commented on what he perceived to be deficiencies in his position. He commented that he had no authority over the Regional Directors. For example, in relation to a topic discussed later, the collection of blood from prisons, on which consensus was not achieved, he said:

My main recollections were that I was not the boss, that all consultants are equal, that I was merely there to co-ordinate and chair; that individual regional directors had the authority to stick to their view and so on and so forth.

....

So I was there chairing a meeting, and if we didn't get consensus and all agreeing there was no way on a particular issue we could go forward.<sup>62</sup>

**17.63** The view of an operational director was expressed by Dr Perry, the Scientific Director of PFC. He commented on the CSA situation as he found it:

[I]n terms of giving any direction to a strategy for producing products ... they had no role in that at all and had very little knowledge – I think they almost totally deferred to SNBTS managers and also the Scottish Home and Health Department, where they did have medics and scientists that really understood to an extent what we were doing.<sup>63</sup>

The regular meetings of SNBTS Regional Directors were attended by representatives of the SHHD, substantially reflecting the reality of Dr Perry's views.

**17.64** In one area, the control of expenditure, delegated management appears to have been effective at least in formal terms. The SNBTS Management Sub-Committee made an application for funding as part of the CSA's bid in the course of the annual Public Expenditure Survey (the PES). The SNBTS bid, supported by the best evidence available to the Sub-Committee and by information and submissions from the SNBTS Directors and the National Medical Director, was passed to the CSA Management Committee. There it was subjected to scrutiny and amalgamated, so far as acceptable, with other applications, before submission to the SHHD. In practice, recurrent expenditure was generally inflated annually by a percentage uplift. New expenditure required more particular justification. Accountability for expenditure followed the same route. However, this appears to have been more of a paper exercise than a reflection of substantial financial control.

---

<sup>62</sup> Professor Cash – Day 10, pages 42–43

<sup>63</sup> Dr Perry – Day 45, pages 7–8

**17.65** Dr Perry said that, in addition to matters of finance, the CSA took an interest in recruitment, promotion and discipline of staff, ensuring compliance with Whitley Council<sup>64</sup> rules, for example.<sup>65</sup> But that interest did not extend to review of performance. Dr Perry said that his contract required him to report to a committee of management, but ‘in practice very little reporting went on’.<sup>66</sup> He looked on the National Medical Director as the closest he had to an operational manager, a de facto relationship.<sup>67</sup> He said:

[A]s far as the CSA is concerned, I had no experience of – either personally or as group – of the CSA being closely involved in any of the complex decision-making that accompanied the operational management of a blood transfusion service.<sup>68</sup>

**17.66** Dr Perry commented further on contact with SHHD officials:

I think there was quite a regular dialogue between particularly the national medical director but also to an extent regional directors as well if there was a specific topic. There would have been a direct discussion between managers in the SNBTS and officials from the Scottish Home and Health Department particularly if there was a major area of funding that was required or a building development or a major new development, such as heat treating of Factor VIII that required significant funding. Then the Scottish Home and Health Department will have discussed that directly with experts within the Scottish Blood Transfusion Service. And those discussions would not necessarily have included managers or officials from the Common Services Agency. My impression at the time was that the Common Services Agency, if there had been an agreement reached between the Scottish Home and Health Department and the SNBTS on a particular issue, then the CSA would not have interfered or intervened in that because they did not have the expertise or knowledge.<sup>69</sup>

**17.67** Dr Perry’s evidence reflects the position adopted by other SNBTS officials. The CSA and its committees and sub-committees were not involved in any significant way in the delivery of the service over the major part of the period with which the Inquiry is concerned. It appears clear that their independence of active CSA management in the operational aspects of the service continued notwithstanding the structural changes of 1974, 1978 and later years.

**17.68** In substance, central government delegated responsibility to the CSA for certain management functions that, in the event, fell short of operational control over the technical aspects of the delivery of the Blood Transfusion Service. Since the SHHD, and therefore Ministers, controlled funding and health policy, devolution would never have been complete. SHHD officials were involved in technical discussions throughout the period, and those took place in direct contact with the National Medical Director and the Regional Directors. In addition, from 1973 the SHHD organised and chaired annual meetings with Scottish Haemophilia Centre Directors and SNBTS Directors to consider the provision of blood products for the treatment of people with haemophilia. Those meetings provided opportunities to influence decisions. The SHHD also maintained close links with the Department of Health and Social Security (DHSS) and its predecessors in London.

<sup>64</sup> Whitley Councils are joint councils of employers and trade unions, providing a forum for consultation on pay and conditions.

<sup>65</sup> Dr Perry – Day 45, pages 7–8 and 65–66

<sup>66</sup> *Ibid.*, pages 2 and 4

<sup>67</sup> *Ibid.*, page 3

<sup>68</sup> *Ibid.*, pages 8–9

<sup>69</sup> *Ibid.*, pages 9–10

**17.69** In the course of the reference period, decisions were taken and implemented that had important consequences for the delivery of the service, wholly without the participation of the CSA, its committees or sub-committees. Two examples illustrate this in relation to scientific developments, which will be discussed in greater detail later. In November 1984, scientists from the PFC heard at a conference in Groningen that HIV could be inactivated by being dry heated to 68°C for one hour. On return to Scotland they implemented the process changes necessary to test the suggestion, found that the Scottish product would sustain heating at 68°C for two hours and proceeded to implement the changes, with great advantage to National Health Service patients dependent on Factor VIII therapy. At the end of 1985, PFC scientists abandoned research on pasteurisation of Factor VIII concentrate, and adopted a dry heat-treatment process for virus inactivation. They were again successful. Objectively, the process changes involved real and significant policy decisions relating to the delivery of the service. They were implemented without reference to the CSA and its committees.

**17.70** In relation to medical matters, in 1991–93 the Edinburgh and South-East Scotland Region undertook a look-back exercise relating to the transmission of Hepatitis C, that was not referred to the CSA or its committees, and was arguably a direct challenge to SHHD policy. It proved the practicality of look-back, and contributed significantly to the UK Government's decision in 1995 to adopt look-back for the whole country.

**17.71** These are examples only and do not tell the whole story. Some elements of the blood transfusion function have changed over time, and central policies have had a direct impact. For example, fractionation of human blood and the production of coagulation factors ended in 2006. That was the result of a strategic review by the Board of NHS National Services Scotland on the future of the Protein Fractionation Centre and Diagnostics Scotland which was initiated in 2004. The review resulted in the closure of the Protein Fractionation Centre in 2007 and the removal of the production of blood fractions from the functions of the CSA in 2008. Other functions have been added, some reflecting technological changes in the use of human cells and tissue which are not relevant to the Terms of Reference. Again, policy decisions have played a part in such innovations. However, as expressed on its web page 'Meeting the transfusion needs of patients in Scotland', the SNBTS perceives its role to be comprehensive:

Our key priority is to ensure that NHS Scotland has enough blood to meet the transfusion needs of patients in Scotland. It is our responsibility to make sure that blood tissues and cells are available when patients need them.<sup>70</sup>

**17.72** Delegation of the functions of the Secretary of State, and later the Scottish Ministers, for the provision of blood for transfusion remains in place, much as it was under the 1974 Order. But until the end of the last century the reality of SNBTS management was often very different from what the formal structures would have suggested. Apart from a few specific situations, which will be noted in context, the formal management structure was irrelevant to the functioning of the service. That structure provided a route for setting budgets and for financial accounting, but did not impinge on the medical, scientific or technical operations of the SNBTS. On one view, it cloaked an underlying failure to integrate fully the operational activities of the Blood Transfusion Service in Scotland, perhaps until the re-organisation in the late 1990s. On another, it was a

<sup>70</sup> Scottish National Blood Transfusion Service, 'About Us: Meeting the transfusion needs of patients in Scotland', <http://www.scotblood.co.uk/about-us.aspx>

pragmatic response to the reality that while governance required a management structure within NHS norms, effective delivery of the transfusion service depended on the regional and functional autonomy of the specialist directors and staff of the SNBTS.

**17.73** In considering, the role and structure of the CSA from its formation onwards, and, in particular, its oversight of the Blood Transfusion Service, it has to be borne in mind that the concept of corporate governance did not start to develop in the UK until reports such as the Cadbury Report and the Nolan Report on Standards in Public Life were issued in 1992 and 1995, respectively. Clinical governance also began to develop around the same time. Its introduction into the NHS in Scotland was announced in 1998 in NHS MEL (1998) 75 as one of the commitments contained in the 1997 White Paper, *Designed To Care*. The 2002 Review of the CSA made a number of recommendations including that the purpose, function and structure of its Board should emulate that of NHS Boards. Those changes were implemented and are reflected in current governance arrangements. Blood, Tissue and Cells (SNBTS) is one of the six Strategic Business Units of the CSA. The Strategic Business Units incorporate most of the divisions that were part of the CSA (now renamed NHS National Services Scotland) since its inception, along with others that have joined or been established over the years. The Board's Clinical Governance Sub-Committee provides strategic oversight and scrutiny of the SNBTS. SNBTS has a Clinical Governance and Safety Group to ensure effective clinical governance at a tactical and operational level. It reports to the Board's Clinical Governance Committee and its role is to ensure the safety and consistent quality of blood, tissues and cells and that service requirements are being met.

**17.74** The Scottish Government's Closing Submission to the Inquiry about the functioning of the system was:

The formal lines of communication were followed in so far as submission of funding bids was concerned. It does not appear from the evidence, however, that there was strict adherence to the formalities in relation to issues of medical or scientific policy; nor indeed was there rigidity about the level at which communications took place between SHHD and CSA .... [T]he reporting system ought to have led from SNBTS to the managing committee of CSA, and the formal position was that SNBTS directors were responsible to the Blood Transfusion Service subcommittee of the CSA management committee. But in practice this route was evidently not always taken .... Thus while there were clearly established lines of communication, these were not slavishly adhered to, ensuring that where appropriate matters could be raised and resolved with reasonable speed and at the appropriate level.<sup>71</sup>

**17.75** It is not clear that SNBTS directors were formally responsible to the Blood Transfusion Service sub-committee of the CSA until the later 1990s. Otherwise, it is a masterly and restrained summary. How far it reflects the realities of the situation will best be seen in relation to the disposal of particular issues relating to management which will be discussed in context. At this stage it is sufficient to note that in some contexts, the formal structure was ignored as irrelevant to the delivery of the service, and SHHD officials were complicit with SNBTS professionals in the development of practical expedients which implicitly acknowledged the unsuitability of the formal structure for management of a highly specialised service.

---

<sup>71</sup> Submission to the Inquiry on behalf of the Scottish Government [PEN.019.0274] at 0280–0281

**17.76** However, the problems that arose were not wholly attributable to the management structure of the CSA. There were other issues that arose from the independence of the Regional and National Directors.

### **The role of the Transfusion Director and the National Medical Director**

**17.77** The scope of the Regional Transfusion Directors' responsibilities was described by Dr Brian McClelland.<sup>72</sup> Dr McClelland held a number of progressively more senior posts in Edinburgh and the South-East of Scotland BTS and at Edinburgh University from 1977 to 2001.<sup>73</sup> In 1979 he was appointed Regional Director. Dr McClelland's job description as Regional Director contained no reference to managerial accountability. It imposed overall responsibility for ensuring that the full range of the service was efficiently carried out. It stated that in practice the responsibility for the administration of budgets was delegated to Regional Transfusion Directors. In terms of national management of the service, it was stipulated that the director would be expected to share with the other Transfusion Directors the responsibilities involved in coordinating the national service as a whole. The director was expected to attend the regular meetings of the Transfusion Directors to discuss matters of common interest, usually under the chairmanship of the National Medical Director.

**17.78** The job description did not require the post holder to report to or accept review by a line manager. Subject to the obligation to co-ordinate the service with other Regional Transfusion Directors, each director was autonomous to a significant degree.

**17.79** Dr McClelland pointed to change from the mid-1980s. The appearance of AIDS, the commencement of regulatory inspections of the transfusion services, the enactment of the European Directive on consumer protection and the development of the guidelines for the transfusion services in the UK led to progressive convergence of practices among the UK transfusion centres.<sup>74</sup> Until then the service was characterised by its history: it was composed of distinct regional services, each with a strong sense of local identity and under its own director. Dr McClelland noted that:

Despite the reassignment of management of SNBTS from the SNBTA to the CSA, the Regional Transfusion Centres (RTCs) remained largely autonomous entities. In respect of blood donor selection, the Region Transfusion Director (RTD) and his/her consultant colleagues determined their own local policies and issued guidance to medical and nursing staff ....

Discussions between RTD's at national level were just that, and they often agreed to disagree. Moreover, the concept of clinical freedom was sacrosanct  
....<sup>75</sup>

Dr McClelland said:

[I] would simply like to explain that ... looking at it now, it does seem rather odd that an organisation which calls itself a national organisation did appear to be behaving in many respects as a series of regional organisations. And you know, the truth is that at this period, at the time that I joined it, it very much

<sup>72</sup> Dr McClelland's statement on collection of blood from 'higher risk' donors [WIT.003.0072] at 0073

<sup>73</sup> Dr McClelland – Day 9, page 2

<sup>74</sup> Dr McClelland's statement on collection of blood from 'higher risk' donors [WIT.003.0072] at 0074

<sup>75</sup> Ibid [WIT.003.0072] at 0072–3

was a series of regional organisations and that was where it had come from and the level of sort of autonomy that at that time rested with the regional directors was not actually particularly unconventional. The health service in its totality was a very different place in the 70s and 80s from what it is now.<sup>76</sup>

**17.80** From 1979 Dr, later Professor, John Cash held the post of National Medical Director.<sup>77</sup> His views on his role have already been noted. In addition to the comments already quoted he said:

[T]here are documents, plenty of documents, available .... in which I write to the CSA and the department and we have letters back from them. In actual fact, trying to get clarification as to my management role in the SNBTS at that time, and what clearly came back -- and I had long discussions with .... the deputy chief medical officer -- was that I was the first among equals.

Eventually, I took the view -- this is much later in the 1980s -- that this wasn't .... going to work and we needed a general manager and they changed the management structure .... So I was there chairing a meeting, and if we didn't get consensus and all agreeing there was no way on a particular issue we could go forward. Looking back, the wonderful thing is in the main we nearly always did get consensus, as a result of which we were enormously successful in many .... areas.<sup>78</sup>

**17.81** Notwithstanding Professor Cash's view of the practical success of the service, which differed to some extent from Dr McClelland's, it is clear that for much of the reference period the service lacked a coherent strategic control structure and the guidance that might reasonably have been expected to flow from that. Given prevailing opinion on clinical autonomy, devising and enforcing an effective structure would have been challenging at any time in the 1970s and early to mid 1980s. The arrival of AIDS changed attitudes, and provision of guidance on practice became more acceptable. However, there was lack of a developed system of clinical governance, as found by the 2002 Review, and the issue was never put to the test.

**17.82** As is clear from the selection of written comments referred to above, from the beginning those with professional responsibilities for delivering the service had reservations about the management structure. By 1990, when the radical changes already mentioned were introduced, many of the events that gave rise to the issues related to the transmission of infection with which the Inquiry is concerned had largely passed into history.

### The role of the clinician

**17.83** RTC medical staff did not have direct clinical responsibility for the care of patients and were not clinically responsible for the transfusion of patients before or after the inception of the SNBTS. Those responsibilities remained with the individual consultants who had under their care patients requiring transfusions of blood or blood products. The concept of clinical freedom was important to the medical and surgical consultants. A surgeon, for example, would decide on the likely need for transfusion for a given procedure, without reference to a transfusion specialist. The transfusion specialist or haematologist would

<sup>76</sup> Dr McClelland – Day 9, pages 16–17

<sup>77</sup> Professor Cash – Day 10, pages 2–3: Professor Cash's job title was changed in 1989 to 'Medical and Scientific Director' of the SNBTS, without change in function.

<sup>78</sup> Professor Cash – Day 10, page 43

give advice, if asked, on difficult cases, either in difficult serological or difficult clinical cases.<sup>79</sup> As history was to unfold, clinical freedom extended to the choice of therapeutic blood product, which was to become an issue.

## PFC

**17.84** The main functions and functional departments of the PFC are described in Chapter 19, *Production of Blood Products – Facilities*. In addition to its manufacturing function, the PFC had a research function. The Director of the PFC and other senior personnel provided information and advice on matters of plasma fractionation requested by the SHHD, DHSS and other national and international bodies, as required.

**17.85** The Scientific Director of the PFC, who was responsible for the management of all the activities of the PFC, was accountable to the Management Committee of the CSA until 1991. Thereafter the post was accountable to the SNBTS General Manager/National Medical Director. The PFC Scientific Director was independent of the National Medical Director (for most of the material time Professor Cash). As Dr Robert Perry indicated, accountability was not enforced in review of the Scientific Director's operations. The effective independence of the scientists at the PFC will be discussed in context.

## The modern service

**17.86** It is unnecessary to trace in detail the development of the modern service. All administrative organisations change. Issues for the Inquiry that emerge from the position in the 1970s and early 1980s as it has been described here will include whether the characteristics of the organisation increased risk to NHS patients. For example, the collection of blood in prisons, and the approach to donor selection with regard to high risk donations generally, provide a focus for part of this discussion which is dealt with separately in Chapter 26, *Donor Selection – Higher Risk Donors*. But it is appropriate to note that there have been significant changes over the reference period, and that the service as it exists today is rather different from the service in the 1970s and 1980s.

**17.87** From the beginning of the reference period until 1990, the SNBTS National Medical Director/National Medical and Scientific Director and the Regional Transfusion Directors were not formally accountable to the CSA Blood Transfusion Service Sub-Committee of the CSA Management Committee. In 1990 the post of SNBTS General Manager was created and the directors were made accountable to the General Manager on managerial aspects, and were professionally accountable to the National Medical and Scientific Director. There was one central body, the Management Board, through which all policy and strategic decisions passed.<sup>80</sup> The Management Board comprised the General Manager, the National Medical and Scientific Director, the Regional Directors, the Director of the PFC, the Director of the National Science Laboratory, the National Finance Manager, the National Donor Services Manager and the National Administrator.<sup>81</sup> The CSA Management Board met for the first time on 19 June 1990 to finalise its remit in the new structure.<sup>82</sup> A Medical and Scientific Committee (the MSC) was established to provide a scientific and professional forum for the SNBTS.<sup>83</sup> The MSC would present its recommendations on medical and

<sup>79</sup> Professor Turner – Day 7, pages 4–5

<sup>82</sup> Minute of Meeting [SNB.002.4726]

<sup>83</sup> Minute of Extra-ordinary Meeting of the Medical and Scientific Committee, 14 August 1990 [SNB.002.4930]

scientific matters to the Management Board, reducing the need for detailed discussion of such matters by the Board. From this time on there was a greater degree of centralised management.

**17.88** Re-structuring of the SNBTS into a national functional organisation was put in the hands of the National Director, Angus Douglas, in about 1997–98, soon after he took up office. Public consultation followed in 1998, and a major re-organisation of the SNBTS was implemented.<sup>84</sup> The five regional centres continue, but with less autonomy than before, and some services are now managed on a national basis, such as red cell preparation, tissues and the clinical directorate. The directors of the national services are accountable to the SNBTS National Directorate and the Management Board.<sup>85</sup> Part of the reasoning behind the changes was:

[To] allow clinicians to concentrate on closer working with local hospitals in delivering more effective clinical care via the use of blood and blood products ....<sup>86</sup>

**17.89** As a result of the re-organisation, overall coordination, strategy, senior staff appointments, succession planning, representation within CSA and some external relationships, audit and quality audit became the responsibility of the National Director. The National Medical and Scientific Director became responsible for clinical services, blood bank management, clinical apheresis, clinical laboratory services, research and development, and relationships with external medical organisations. Other national directorates, as set out in the SNBTS Annual Report for 1999–2000 were:

- Blood Supply Chain
- Plasma Products (PFC)
- Diagnostics Scotland
- Bone and Tissue Products
- Products and Clinical Services<sup>87</sup>

**17.90** The Regional Transfusion Directors were re-designated Clinical Directors reporting to the National Medical and Scientific Director. Some services remained local. Hospital blood banking, the provision of advice and information on transfusion medicine to hospitals and some diagnostic services remained based in the regional centres, but generally the service was centrally controlled.

**17.91** The Directorates have changed from time to time. For present purposes it is unnecessary to trace these changes. They continued to reflect changing demands for effective management structures within the SNBTS, starting from the 1998 re-organisation. For present purposes, the importance of these developments lies in the contrast they provide with the situation that obtained throughout the material part of the reference period — when decisions were required that had an impact on the functioning of the Blood Transfusion Service in face of many and fundamentally changing demands.

<sup>84</sup> Scottish National Blood Transfusion Service, Strategic Proposals Consultation Document [SGH.007.2327] Consultation began on 27 May 1998 and ended on 26 August 1998.

**17.92** The management structure of the Blood Transfusion Service inevitably forms part of the context in which the delivery of blood, blood components and blood products for clinical use has to be discussed. The critical period arising from the Terms of Reference ends in the early 1990s, by which time blood for clinical use was effectively screened for infection with HIV and HCV and blood products were effectively treated to inactivate virus infection.

### **Conclusions**

**17.93** From the inception of the National Health Service:

- The Secretary of State for Scotland, Scottish Health Ministers, and Scottish Home and Health Department civil servants had control of health care policy.
- Until 1974 operational control of the delivery of the service was not exercised in relation to the operations of the SNBTA which provided blood transfusion services as an independent body, increasingly funded by Exchequer grant.
- In 1974 the Secretary of State delegated to the CSA responsibility for the provision of supplies of human blood for the purposes of carrying out blood transfusion and related services, including the production of blood fractions.
- In practice, the CSA did not exercise operational control over the Blood Transfusion Service.
- Both before and after 1974 the Regional, and latterly the National Medical and PFC Scientific Directors, of the Service had largely autonomous control of their respective operations, exercised independently of the CSA.
- In general, in relation to operations of the Blood Transfusion Service requiring specific funding or policy decisions, there was much direct contact between Regional, Medical and the PFC Scientific Directors of the Service and officials of the SHHD that did not involve the CSA.

## CHAPTER 18

### COLLECTION OF BLOOD – GENERAL

**18.1** As discussed in Chapter 25, *Screening of Donated Blood for Hepatitis B*, the development and application of screening tests for the presence of Hepatitis B antigen and antibody, perceived at the time to be increasingly effective, had a central role in mitigating the risks of transmission of viral infection during the first decade of the reference period. The limitations of the technology available were noted at the time. Though the predicted effectiveness of the screening tests available improved over that period, tests never achieved detection rates for Hepatitis B of more than about 50% even in the best circumstances. Other means had to be relied on as they became known, not only for detection of Hepatitis B infection, but for other risks of transmission of viral infection. This chapter examines the procedures adopted. It is important to note, however, that in the perceptions of the time, reliance on screening technology defined the context in which other measures were put in place, at least from the end of 1972 when screening for Hepatitis B surface antigen (HBsAg) became general throughout the UK. Whatever their limitations, they were the best tools available.

**18.2** This chapter discusses blood donation collection practice generally, leaving topics relating to the acceptance of blood from 'higher risk' donors for separate discussion. Inevitably, increasing knowledge of the risks of transmission of disease was a further factor in changes in practice. Most of the chapter will deal with the earlier part of the reference period, taking account of changes in practice related to specific risks and noting technological change relevant to those changes, where appropriate.

#### **Blood collection: the voluntary principle**

**18.3** Well before the beginning of the reference period, both within the UK and internationally, there was a widely held view among government and specialist organisations, that purchased blood carried a relatively high risk of transmitting hepatitis. The report of the World Health Organization Scientific Group on Viral Hepatitis, *Viral Hepatitis*, Number 512 of the Technical Report Series in 1972, recognised a wider range of factors relating to the risk of transmission of the Hepatitis B virus (HBV):

Great variations in the prevalence of hepatitis B antigen in apparently healthy blood donors have been found in different parts of the world. Prevalence also varies with such factors as the socioeconomic status and sex of the donor, whether he is a volunteer or paid, and whether he lives privately or in an institution. Antigen has been detected most frequently in males in the younger age-groups.<sup>1</sup>

Some of these factors, in particular gender and socioeconomic status, would have been unlikely to have influenced donor selection in the UK at any period. However, payment was a factor that could be dealt with as a matter of general policy.

---

<sup>1</sup> 'Viral Hepatitis: Report of a WHO Scientific Group', *World Health Organization Technical Report Series*, 1973, No. 512 [SGH.002.9746] at 9761

**18.4** As noted in Chapter 17, *Blood and Blood Products Management*, paragraph 17.13, with the formation of the Scottish National Blood Transfusion Association (SNBTA) in 1940, voluntary donation became the rule throughout Scotland, and funding and collection procedures took on the character of voluntary charitable activities. In war time, voluntary donation was an obvious response to the call to assist the blood transfusion service. The programme had considerable success: see Chapter 17 at paragraph 17.15.

**18.5** By 1975–76, when the Scottish National Blood Transfusion Service (the SNBTS) had largely superseded the SNBTA in the collection and supply of blood for clinical use, the scale of the activities had increased dramatically, and a high level of blood collection was maintained thereafter.

**18.6** At the beginning of the reference period, the voluntary nature of blood donation was universally accepted and admired. Dr Brian McClelland reflected a common view among Blood Transfusion Service personnel:

I think people in the UK were extremely proud of the voluntaryism [sic] and the voluntary system and they knew it was morally better and they probably felt also that it was microbiologically safer. It was safer.<sup>2</sup>

**18.7** The World Health Organization (WHO) was a prominent supporter of the voluntary principle internationally. It published guidance in 1971: *Guide to the Formation and Operation of a Transfusion Service*, aimed specifically at countries lacking a developed blood transfusion service.<sup>3</sup> According to its preface:

The present book is intended to help physicians and pathologists who, after receiving a basic training in blood transfusion, are entrusted with the responsibility of establishing and developing transfusion services in their own countries, either under the ministry of health or through the agency of a voluntary organization, such as a Red Cross Society.<sup>4</sup>

The relevance of the book to developing knowledge of hepatitis is discussed in Chapter 14, *Knowledge of Viral Hepatitis 1*.

**18.8.** The *Guide* encouraged voluntary donation, identifying concealment of previous illnesses like jaundice as a risk associated with paid donation, implicitly recognising that a history of jaundice was a contra-indication to receiving blood from individuals who had been infected.<sup>5</sup> The guidance commented that paid donors were mostly ‘from the lowest social strata where alcoholics and drug addicts are often found’. That, and the risk that paid donors might form syndicates and from time to time demand an increase in financial recompense, were said to have brought paid blood donations into disrepute in many places.<sup>6</sup> As regards voluntary unpaid donors, the *Guide* stated:

‘The voluntary unpaid blood donation is a humanitarian act towards the sick by the healthy .... Under this system it is easier to verify the donor’s state of health, since – unlike some paid donors – he has no reason to try to conceal illness’.<sup>7</sup>

<sup>7</sup> Ibid [PEN.002.0462] at 0473

**18.9** In May 1975, the WHO passed Resolution 28.72: *Utilization and Supply of Human Blood and Blood Products*.<sup>8</sup> The resolution urged Member States to promote the development of national blood services based on voluntary non-remunerated regular blood donation; to enact effective legislation governing the operation of blood services; and to take other actions necessary to protect and promote the health of blood donors and of recipients of blood and blood products. In January 1987, the 79th session of the WHO at Geneva reiterated its support for resolution WHA28.72.<sup>9</sup> Subject to qualifications relating to developing countries, from the outset of the reference period the WHO advice was consistent: Member States should adopt the voluntary principle and take steps to embed it in effective legislation. The picture that emerges is of consistent support for the voluntary principle.

**18.10** There is perhaps no better way of characterising the voluntary donor in the systems in place in the UK at about the beginning of the reference period than by reference to what Professor Richard Titmuss, author of *The Gift Relationship*, said in a presentation to a joint symposium held by the Royal Society of Edinburgh and the Royal College of Physicians in February 1972:

[T]he primary characteristics of the voluntary donor ... [are]: the absence of tangible immediate rewards in monetary or non-monetary forms; the absence of penalties, financial or otherwise, for not donating; and the knowledge among donors that their donations were for unnamed strangers without distinction of age, sex, medical condition, income, class, religion or ethnic group.

No donor type can, of course, be said to be characterised by complete, disinterested, spontaneous altruism. There must be some sense of obligation, approval and interest; some awareness of need and of the purpose of the blood gift; perhaps some organised group rivalry in generosity; some knowledge that fellow-members of the community who are young or old or sick cannot donate, and some expectation and assurance that a return or reciprocal gift may be needed or received at some future time. Nevertheless, in terms of the free gift of blood to unnamed strangers there is no formal contract, no legal bond, no situation of power, domination, constraint or compulsion, no sense of shame or guilt, no gratitude imperative, no need for penitence, no money and no explicit guarantee of or wish for a reward or a return gift however many donations are made. They are acts of free will; of the exercise of choice; of conscience without shame.

Virtually all donors in Britain ... fall into this category.<sup>10</sup>

**18.11** As is clear from international guidance, the generally accepted view was that blood collected from unpaid volunteers was inherently safer than blood collected from individuals paid for their blood. While it was logically indefensible to infer that blood collected from unpaid volunteers was safe, adherence to the voluntary principle gave a high degree of confidence in the safety of donated blood, and that clearly had an influence on the practices adopted in the management of the collection process.

<sup>9</sup> World Health Organization Executive Board, Seventy-Ninth Session, Geneva, 12–23 January 1987: EB79.R1 Blood and Blood Products [PEN.019.1382]

<sup>10</sup> Titmuss, 'The Blood Donor' *Proceedings of The Royal Society of Edinburgh*, section B (Biology) 1972; vol 71 Supplement. s. 59 at s. 61 [PEN.002.0570] at 0571. Professor Titmuss was Professor of Social Administration, The London School of Economics and Political Science.

**18.12** The events that created the risks of transmission of the infections with which the Inquiry is concerned (HIV/AIDS and HCV) happened during the period up to 1991 when there was continuing growth in the volume of donations. The pattern of blood collection in Scotland from 1975–1990 is shown in Figure 18.1.<sup>11</sup> The data reflected in this graph are net of rejections or deferrals.<sup>12</sup> The values in the graph rose from 212,061 usable donations of blood in the year ended 31 March 1975 to 301,741 usable donations in the year ended 31 March 1990. The picture overall is one of steady growth. Technological innovations contributed to the developing picture. Plasmapheresis helped boost total blood collection. Data on plasmapheresis are not available on a consistent basis across this period, but there was a steady rise throughout the 1980s, reaching over 15,000 donations in 1990.

**Figure 18.1 Blood Donations 1975 to 1990**

**18.13** For immediate purposes, Figure 18.1 illustrates the success of the SNBTS in recruiting donors and maintaining growth in the volume of blood collected for direct clinical use in transfusion, and for the manufacture of blood products, during the critical part of the reference period. It is impossible to say to what extent individual donors were aware of the many uses to which their donations were put, but it appears that to generate these increasing levels of donation, there must have been confidence generally in the benefits conferred on others by the effective use of donated blood. There was clearly, in Professor Titmuss's words 'some awareness of the need and of the purpose of the blood gift'.<sup>13</sup>

<sup>11</sup> The data have been derived from extant SNBTS and PFC records that were not maintained on a consistent basis over the whole period. The data reflected in Figure 18.1 were published in the Preliminary Report paragraph 5.52 and were not challenged in later evidence. As at 1990, the total for donations before deferrals was 332,236. Data on donations from 1991 to 2009 are summarised in SNBTS Infection Surveillance Report No. 11 [PEN.001.0053] at 0055 and 0056. Donations in 1991 totalled 358,359. Total annual volume remained over 300,000 until 1995 after which it fell progressively to about 250,000 donations per annum.

<sup>12</sup> Donations before rejections and deferrals for part of the period are presented in Chapter 26, *Donor Selection – Higher Risk Donors*, at Appendix 2.

<sup>13</sup> Titmuss, 'The Blood Donor' *Proceedings of The Royal Society of Edinburgh*, section B (Biology) 1972; vol 71 Supplement. s. 59 at s. 61 [PEN.002.0570] at 0571

**18.14** Regular donors always were, and remain of, considerable importance to the effectiveness of blood collection in Scotland. As illustrated in the Preliminary Report, data for the mid-1970s indicates some turnover in donors.<sup>14</sup> That seems to have been inevitable, and to be a continuing feature of voluntary donation, given the peripatetic nature of collection and basic human nature. Individually, donors' patterns of activity would have varied and still do vary. Apart from regular donors called up for a specific session, there must inevitably be an element of chance in matching the timing and place of a session to the availability and needs of prospective donors. Perhaps there is also a variability of response inherent in the voluntary principle, given the variability of donors' circumstances. Seasonal shortages occurred in some areas from time to time, while emergencies created exceptional demand. Viewed broadly, however, the data illustrate a reasonably steady state of commitment. The total figures imply a high percentage of return donors: Approximately 80% of the donors bled were not 'new'. At the present time, return donors contribute about 85% of all donations.<sup>15</sup> Consistency in total supply was achieved notwithstanding these levels of variation.

**18.15** Dependence on a high proportion of regular donation was a general phenomenon related to increasing demand for blood for transfusion and therapeutic application. Professor Titmuss commented in 1972 that it was becoming clearer to those responsible for organising recruitment programmes that:

[E]ffective transfusion services cannot be run on the basis of dramatic and 'crisis' appeals to transient or sporadic givers or suppliers of blood.<sup>16</sup>

**18.16** Professor Marc Turner emphasised that the importance of voluntary donors went beyond maintaining the volume of blood available to the service. Regular donors were registered and could be called upon to form a core for planned sessions, ensuring a structured approach to the collection of human blood and its components. In addition, because they were subject to regular screening, returning donors had a much lower deferral rate than new donors.<sup>17</sup> Donor selection practice and procedures would be expected to reflect the characteristics of the donor population, and in particular the high proportion of return donors comprised in it. The lower deferral rate among return donors supported confidence in the safety of most of the supply.

**18.17** The corollary of donor commitment was reflected in the transfusion service's recognition of an obligation of care for the health of donors, as well as the health of recipients of blood and blood components. Recognition of this obligation was a further factor that had a significant bearing on donor selection practice. In a discussion on recruiting methods, the WHO *Guide to the Formation and Operation of a Transfusion Service* stated:

The motto of the medical director should be: "Without the donor panel there would be no blood transfusion service; therefore the convenience, comfort, and wishes of the donors should be given every consideration." For the donor organizer the motto should be: "The blood must be available in the quantity needed, at the place and time required. All other considerations are subservient to this."<sup>18</sup>

<sup>14</sup> Preliminary Report, paragraphs 5.50 and 5.51, based on the SNBTS Annual Report for 1975–1976: [SNB.010.3921]

<sup>17</sup> Professor Turner – Day 7, pages 15–23

<sup>18</sup> *Blood Transfusion: a Guide to the Formation and Operation of a Transfusion Service* [PEN.002.0462] at 0474

**18.18** Within the UK's blood transfusion services, and the SNBTS in particular, the implications of relying on a voluntary system were recognised:

Firstly, the goodwill of the donor population is essential and the utmost care is necessary to ensure that no individual nor collective causes for dissatisfaction arise. To a large extent this depends on a high state of morale and dedication on the part of all members of the SNBTS, including voluntary workers, and it is essential that this be kept to the forefront in any discussions on transfusion policy and its implementation.<sup>19</sup>

**18.19** In its submission to the Royal Commission on the National Health Service, dated February 1977, the SNBTS said:

16. A fact so obvious that it is often overlooked by clinicians and NHS management is that human blood and its constituents cannot be manufactured but must be obtained from members of the general public ....

17. The benefits of a voluntary donor system, in terms of purity of blood and reliability of the donor, were recognised in resolution No. WHA 28.72 passed at the 28<sup>th</sup> World Health Assembly in 1975 which fully endorsed the principle of voluntary donation and urged the governments of all nations to adopt the highest standards in providing a safe blood service to their citizens, formulating those standards on the concept of non-remunerated donors.

18. It is strongly felt in this service that the Central Departments in England and Scotland should be asked to pronounce publicly their support for voluntary blood donation and to consider its implications for the management and finance of the blood transfusion service. SNBTS feels that the indispensability of blood donors should be recognised by their being given an opportunity to participate once more in the management of the service as was the case before NHS reorganisation. Equally, the Central Departments should be taking active steps to counter the threat to voluntary blood donation posed by those multi-national pharmaceutical companies who are marketing in Scotland products, made from the blood of paid donors, which the blood transfusion service also manufactures from voluntary blood donations. This can be done by acknowledging the value of SNBTS products and investing in the service.<sup>20</sup>

**18.20** As indicated in Chapter 17, *Blood and Blood Products Management*, there was during this period a degree of concern among senior SNBTS officials related to structural changes in the Blood Transfusion Service at the time and the tone of the comment probably reflects that concern.<sup>21</sup> It is likely that the need for express political commitment to the voluntary principle indicated a lack of confidence on the part of SNBTS senior management that the principle was entirely secure at the material time. However, despite these observations, the voluntary principle remained intact, and universal support for it has been assured. Occasional threats of intrusion into the UK blood supply system by commercial pharmaceutical companies failed to materialise.<sup>22</sup> The collection of blood in Scotland remained, and remains, in the hands of the SNBTS, supported by the Scottish

<sup>19</sup> SNBTS Annual Report 1975–76 [SNB.010.3921] at 3922

<sup>20</sup> Royal Commission on the National Health Service: Evidence from the SNBTS, January 1977 [SNB.003.4592] at 4599

<sup>21</sup> See Chapter 17, *Blood and Blood Products Management*, at paragraphs 17.28 to 17.47

<sup>22</sup> Dr Wallace, regional director of the Glasgow and West of Scotland BTS, reflected his general concern in a letter dated 24 November 1976: [SNB.003.4539]. In September 1980, there was a proposal in England that Beechams should take over BPL: [DHF.003.0329]

National Blood Donors Association (the successor to the SNBTA) as a voluntary donation scheme.

### Collection procedures

**18.21** Despite the reassignment of the management of the SNBTS to the CSA in 1974, the Regional Transfusion Centres remained largely autonomous entities as far as many professional matters were concerned. The SNBTS said:

In respect of blood donor selection, the Regional Transfusion Director (RTD) and his/her consultant colleagues determined their own local policies and issued guidance to medical and nursing staff. Documents, for example information for donors, session records, publicity materials etc, were designed and printed locally, albeit with a national logo. Discussions between RTDs at national level were just that, and consensus was not always achieved.<sup>23</sup>

Dr John Gillon, searching through the SNBTS archive, could find no specifically Scottish documents containing details of donor selection procedures prior to about 1982. It appears that such documentation relating to donor selection criteria before 1982 had either been destroyed or lost with the passage of time.

**18.24** There was a progressive shift away from this position from the mid-1980s.<sup>24</sup> The SNBTS characterised this shift as a move from ‘more of a federation of collaborating centres than a national service’, towards general management and ultimately a national service with (generally) common systems, after re-organisation in 1999.<sup>25</sup>

**18.25** The position in respect of collection of donations can be contrasted with the approach adopted to transfusion and to manufacture of blood products. *Notes on Transfusion* were intended primarily for use by medical staff in hospitals.<sup>26</sup> They were not prescriptive. But they were issued by the DHSS, the SHHD and the Welsh Office jointly for the NBTS and the SNBTA, and carried the authority of the departments. The fifth edition was published in 1973. *Standards for the Collection and Processing of Blood and Blood Components and the Manufacture of Associated Sterile Fluids* was first published in 1979.<sup>27</sup> Revised editions were produced from time to time thereafter. The Standards were compiled by: the Department of Health and Social Security (DHSS) in England and Wales in consultation with the Regional Transfusion Directors (RTDs) of the NBTS and the SNBTS; the Directors of the fractionation laboratories – the Blood Products Laboratory (BPL) and Protein Fractionation Centre (PFC) – and the Scottish Home and Health Department (SHHD). The Standards were focused on aspects of collection and processing that might have a bearing on the safety and quality of blood products. Certain illnesses and conditions were identified as disqualifying a person from being a donor, including illicit drug taking, current jaundice or hepatitis or the presence in the blood of HBsAg. Deferment, or discretionary disqualification, applied where the person reported jaundice or hepatitis

<sup>27</sup> The 1979 edition of the *Standards etc* are [PEN.002.0249]. The Medicines Division, through the DHSS, also produced a *Guide to Good Pharmaceutical Practice* (known as ‘the Orange Book’), the first edition of which appeared in 1971. The second edition of the Orange Book was published in 1977 [DHF.001.2933] and the third edition in July 1983 [DHF.001.4990]. The current edition is *Rules and Guidance for Pharmaceutical Manufacturers and Distributors*, published in 2007 by the Medicines and Healthcare Regulatory Agency (MHRA). The guide still has an orange cover.

in the preceding year or contact with ‘a case’ within six months. Temporary deferment applied to an individual who had tattooing, acupuncture or ear-piercing within six months or who had a transfusion within that period. It was stated that the Standards should not be construed as comprehensive guidance on donor selection. Though not prescriptive or comprehensive, the Standards also had the authority of the health departments involved.

**18.26** In England and Wales, the National Blood Transfusion Service (NBTS) produced a *Memorandum on the Selection, Medical Examination and Care of Blood Donors*. The SNBTS Directors ‘noted’ the final version of the original document on 8 May 1978 when they expected that the document would be incorporated into the *Standards*.<sup>28</sup> However, it remained an independent document. The Inquiry has found versions of the *Memorandum* produced in 1977,<sup>29</sup> 1983,<sup>30</sup> 1985<sup>31</sup> and 1987.<sup>32</sup> Scottish Regional Directors used the 1977 *Memorandum* as guidance, and participated in its revision. Professor Stan Urbaniak indicated that his predecessor, Dr Brodie Lewis, used it and that he used it during his own tenure as Regional Director from 1983 onwards. Dr Ewa Brookes found it in use when she became the Regional Director at Dundee in 1981 and continued its use. Dr McClelland stated that his understanding was that ‘all the SNBTS regions had based their procedures on the 1977 guidance document’. Dr Ruthven Mitchell indicated that he also used the *Memorandum*. The extent to which the guidance was adapted for local use was not explored.

**18.27** Specific questions relating to the health of the donor were included in the *Memorandum* from 1977 onwards. It was stated that the donor’s medical history should be coupled with a careful assessment of the donor’s appearance:

‘The experienced doctor can detect at a glance the potentially unsuitable donor. Those of poor physique or who are underweight, the debilitated, the undernourished, the mentally unstable, and those bearing the obvious stigmata of disease should not be bled’.<sup>33</sup>

However, dependence on the donor was emphasised. The 1977 iteration stated:

A donor is the best judge of whether he is in normal health and truthful answers to simple questions concerning his medical history and general health form the main part of the examination.<sup>34</sup>

This was said against the background of recognition that a complete medical examination was impractical and that superficial medical examination, by auscultation (examination by stethoscope) and percussion of the chest, and measuring pulse and blood pressure, was in most cases of no great value. In some respects, the *Memorandum* repeated the *Standards*. Directions relating to tattooing, acupuncture or ear-piercing or those donors who had had a transfusion were the same in both publications.

<sup>34</sup> *Ibid* [SNB.002.5348]

**18.28** In relation to jaundice or hepatitis (then treated for many purposes as the same condition), the 1977 *Memorandum* provided:

Individuals who give a history of jaundice or hepatitis or in whose blood anti-HBsAg is present may be accepted as donors providing that they have not suffered from jaundice or hepatitis in the previous twelve months, have not been in house contact with hepatitis or received a transfusion of blood or blood products in the previous six months, and providing their blood gives a negative reaction for the presence of HBsAg when tested by a sensitive method (R.P.H<sup>35</sup> or R.I.A<sup>36</sup>). An accepted test for hepatitis B surface antigen shall be performed each time a donor is bled; donors whose blood reacts positively shall be excluded permanently from the donor panel.<sup>37</sup>

It was also repeated that illicit drug taking, if admitted or suspected, should debar a person from donating.

**18.29** A move away from use of the NBTS *Memorandum* began in about 1982. A revised guide to donor selection was prepared by Edinburgh and South East Scotland Blood Transfusion Service (ESES BTS) in 1982, in response to a comment by the Medicines Inspectorate on the consistency of decision-making regarding which donors to accept or reject.<sup>38</sup> In their response to the Medicines Inspectorate dated 12 January 1983, the ESES BTS noted that a new comprehensive guide to donor selection had been prepared and was in routine use by donor selection staff.<sup>39</sup>

**18.30** The ESES BTS guide comprised three documents: a *Guide to selection of blood donors*,<sup>40</sup> an *Alphabetical Guide to Medical Assessment*,<sup>41</sup> and a health check for new donors.<sup>42</sup> The first of these set out the general conditions to be met before a donation could be accepted. These dealt with the donor's age and weight, distinguishing new first-time donors and return donors, and prescribing the required haemoglobin level. It also restricted frequency of donation. In relation to hepatitis it provided that detection of HBsAg at any time excluded all donations except with the approval of the Transfusion Director. There were general directions related to medical conditions which might exclude donation, permanently or temporarily.

**18.31** The *Alphabetical Guide* contained an extensive list of specific conditions which might affect the acceptability of a donation, with guidance on the response of the session team and in particular the circumstances requiring reference to the doctor in charge. Under 'Hepatitis', the *Alphabetical Guide* provided generally that the doctor should be consulted. Further guidance was:

Defer for one full year after recovery. Check if donor knows he/she is a carrier for serum hepatitis, and if so, put off service. Otherwise, at their first donation 1 year after their recovery record 'Hepatitis' on donor's name slip and inform Hepatitis lab.<sup>43</sup>

<sup>35</sup> Reversed passive haemagglutination

<sup>36</sup> Radioimmunoassay. The use of these tests is discussed in Chapter 25, *Screening of Donated Blood for Hepatitis B*

<sup>37</sup> 1977 *Memorandum* [SNB.002.5348] at 5350

<sup>43</sup> *Ibid* [SGH.003.5059] at 5105

In the case of ‘Hepatitis contact’ donors, where the donor and contact lived together, used the same towels, crockery, etc, the donor was to be deferred for six months after close contact. Recipients of blood transfusion were acceptable as donors six months after transfusion. The directions required staff to check the reason for the transfusion and to consult the doctor or nursing Sister if in doubt.

**18.32** The health check questionnaire was designed to elicit information relating to these and other issues.<sup>44</sup> There was a question on whether the donor had ever had a serious illness or operation, and questions related to piercing, acupuncture and tattoos. There was not a specific question relating to transfusion. But the information required by these guides required discussion and follow-up where the prospective donor gave a positive answer to any of the questions asked. These guidance documents were prepared in response to the Inspectorate’s concerns which the ESESBTS said it shared. It seems reasonable to infer that until 1982 there was no similar, well-structured interview routine in place in that region.

**18.33** In 1985 the SNBTS considered that *The Guidelines on the Care and Selection of Blood Donors*, issued by NBTS (the updated version of the *Memorandum*), required adaptation. Accordingly, the National Medical Director and the Regional Directors requested Dr Gillon, of ESESBTS, to prepare a report comparing donor selection practice in the five regional centres in an attempt to assess the significance of the existing differences between the SNBTS centres and the NBTS guidelines. In his report, dated 11 November 1985, he advised that there was general agreement that the NBTS *Guidelines* were unsatisfactory in format, and that, in addition, each centre criticised particular (and different) items, which he listed. His conclusion was that, having looked at donor selection criteria in the five regions, ‘major differences of opinion are few’, and that differences related to local factors could be accommodated. He had formed the impression that all centres were willing to attempt to reach a consensus and he commented that the ‘evidence suggests that this would be relatively easy to achieve’.<sup>45</sup>

**18.34** In his oral evidence Dr Gillon explained the position as at 1985:

There was a core of consistency .... So really we were working at the margins, largely on issues of donor safety rather than patient safety. By and large I think as far as recipient safety was concerned, there was greater commonality. But for the central core significant issues of patient safety, I don’t think there was any significant difference.<sup>46</sup>

**18.35** The report was considered at a co-ordinating group meeting of the SNBTS Directors on 30 April 1986. It was agreed that there was a need for an SNBTS set of criteria to serve as a framework for use by medical officers and team staff, with specific agreement that it was for each centre to decide who should take clinical decisions on donor acceptance. The Directors present agreed to recommend to the full co-ordinating group that a ‘standard guide’ should be produced, and that the ESESBTS donor selection document provided the basis for that.<sup>47</sup> In November 1988, *Guidance for the Selection of Blood Donors* was eventually agreed and issued.<sup>48</sup> In a note on the front page it was said to ‘represent the collective opinion of SNBTS’.

<sup>47</sup> Minutes of SNBTS Co-ordinating Group meeting on 30 April 1986 [SNB.003.9905] at para 2

<sup>48</sup> *Guidance for the Selection of Blood Donors*, November 1988 [PEN.016.0479]. The document was re-issued in August 1990 [SNB.006.6484] and revised in early 1991 [SNB.011.7435]

**18.36** Use of the 1977 *Memorandum on the Selection, Medical Examination and Care of Blood Donors*, and its revised versions, by the Regional Directors of the SNBTS provided RTDs in Scotland with a common base for developing their own donor selection procedures. A former Regional Transfusion Director has provided the Inquiry with a description of a typical donor session. Session Medical Officers received training and a copy of the 'Guidance' at the start of their work with the Blood Transfusion Service. The donor team included a clerical officer, donor assistants and a team leader together with assistants to carry out the haemoglobin check. The prospective donor was welcomed and asked to read the donor questionnaire. It included the phrase 'Please tell us if you have ever suffered from Hepatitis (jaundice) or been in contact with a case in the past six months'. The donor was then interviewed by the clerk who went through a health check with the donor, the donor signing to confirm that they had read and understood. The haemoglobinist then carried out a finger stick test to exclude anaemia. When a medical query arose, if the Medical Officer could resolve it a note was made on the donor's record card and the donation accepted or temporary deferral advised, as appropriate. If the Medical Officer could not resolve it, the donation was temporarily deferred, GP details were obtained and the query referred to the Regional Centre medical staff. If the reply to the hepatitis/jaundice question was positive the donor was referred to the session Medical Officer, donation was deferred, GP details obtained and the report referred back to the Regional Centre staff. After a satisfactory history and blood check, the donor was made comfortable on the donation bed and the donation was taken. Accordingly, the donor's memory was prompted at three points and sometimes donors then mentioned something, for example, during the donation procedure or during the bed rest period afterwards. The team leader continuously scanned all donors in the premises, principally for signs of nausea or fainting but also for other things, sometimes sufficient to refer to the Medical Officer for another check. Consequently, the assessment of donors did not end until they were fully recovered and left the premises.

**18.37** In the ESESBTS, the conduct of donor sessions followed a similar pattern whatever the location, subject to necessary adaptation in institutions which will be discussed later. Routine donor sessions were arranged well in advance, usually between 12 and 15 months ahead, to allow for all necessary planning.<sup>49</sup> Dr McClelland described the approach in the late 1970s and early 1980s.<sup>50</sup> Donor sessions were conducted by a team. A doctor was always present at the session. There was a senior nurse or team leader and a group of what were then called 'donor attendants'. The donors would be welcomed to the session. In this period they would have been given an information card, which was fairly standard across the UK, which set out a series of exclusion criteria. A donor who had any of the listed features was asked not to donate. Those who were proceeding were seen by a clerical member of staff, who would take them through that card again and ask them questions to confirm that they had read it, record some of the information about the donor and then pass the donor on to another person who, using a finger prick technique, would take a sample of blood which was tested for haemoglobin. Provided the donor passed that test, they would be moved to another waiting area from which they would be taken to lie on the couch and have their blood taken.

<sup>49</sup> Dr McClelland – Day 9, page 18

<sup>50</sup> Ibid pages 19–20 The description related to prisons sessions specifically, but was said to operate identically at any other session.

**18.38** The interview routine was supplemented by observation. Dr McClelland commented that the donor would be seen, talked to and observed by SNBTS staff throughout the whole process of donation. If something struck a member of staff, perhaps even when the donor was giving blood, which caused them to be uncomfortable about the donor's suitability, that issue would be noted and acted on.<sup>51</sup>

**18.39** Matters of interest to staff would include whether a donor was heavily tattooed, which for some reason might not have been noticed at an earlier stage. Further, when the donor's arm was exposed to take a sample, evidence of needle injection tracks might be disclosed. It was not unheard of for a donor to appear to be inebriated. However, Dr McClelland emphasised that there was almost certainly a fair amount of individual variation in the way that individual members of staff assessed donors. He said that it was, and remains, extremely difficult to control practice with a very large team of people operating peripatetically. While the ESESBS had always striven for consistency in the application of donor session standards, he said that that was very difficult to achieve.<sup>52</sup>

**18.40** Dr Mitchell thought that factors related to donor care and maintenance militated against questions that placed the donor in a position in which they would have to self-exclude on grounds of health.<sup>53</sup> He thought it impossible to challenge a donor who asserted that they were healthy, when it appeared that was not true or reliable. In this, and in other aspects of his approach to practice, Dr Mitchell reflected most fully the dedication to the interests of the donor noted in paragraphs 18.15 to 18.17 above.

**18.41** The best evidence of the initial stages in donor procedure in the west of Scotland at the beginning of the reference period was provided by Mrs Rosalind Prior, who was employed by the SNBTS as a Mobile Team Assistant in the region between 1969 and March 1974. She described normal practice in the early 1970s as follows:

The normal practice was that after the donor had passed the haemoglobin test they would move on to another team assistant who would go through a series of questions with them. We didn't have a sheet concerning the questions that we read to the donor and we didn't have a sheet containing the questions which we handed to the donor and asked them to read. We were taught the questions which we had to remember and go through them with the donors. The first question was, "Have you given blood before". If the donor said "Yes" then we would ask "Is it over three months since the last time you donated". If the donor said "Yes" then we would ask, "Is there any reason why you shouldn't donate blood? For example, do you have a cold, flu, boils, abscesses or ulcers?" If the answer was "No", we would ask if they had recently had any injections or vaccinations. If they answered "No" to that we would ask if they had had mumps, measles, chickenpox, shingles or jaundice or been in contact with anyone who had had jaundice or had they had any recent illnesses or operations in the last two years. If the person said yes to any of these questions we would have to go and advise the doctor of this. In the case of jaundice the doctor would tell us that we had to inform the donor that they could donate blood that day but that it would be used for research purposes only. They were also informed that they had to be clear of jaundice for five years before they would be able to donate blood again ....

<sup>51</sup> Ibid page 20

<sup>52</sup> Ibid pages 20–21

<sup>53</sup> Dr Mitchell – Day 9, page 167

The procedure never changed in the five years I worked for the Blood Transfusion Service. We were never told to ask any donors if they had ever used intravenous drugs or had tattoos or piercings. At that time HIV was not known and we were not instructed to ask any questions about hepatitis ....

Just before I finished working with the Blood Transfusion Service they produced the questions that donors had to be asked on a sheet that we used but as far as I can recall the questions weren't any different from what we had previously asked donors.<sup>54</sup>

Mrs Prior's employment ceased at the very start of the reference period, some three years prior to the issuing of the 1977 *Memorandum*. However, Dr Mitchell's evidence noted at paragraph 18.40 suggests that it is unlikely that there would have been any change in the instructions to session staff in the West of Scotland relating to questioning about health.

**18.42** Full compliance with the requirements set out in the *Standards* and the 1977 *Memorandum* would have changed the procedure described by Mrs Prior to some extent. However, the most detailed evidence about what happened in a donor session came from her. The descriptions given by the former Regional Transfusion Director and Dr McClelland of donor sessions in their regions were very similar. Dr Gillon found differences in practice, sometimes a higher standard being applied, sometimes a lower one. His ultimate conclusion was that as far as recipient/patient safety was concerned there was not any 'significant difference'. However, as noted in paragraph 18.35, the view of the members of the co-ordinating group who discussed Dr Gillon's report was that there was a need for a Scottish framework for use by medical officers and team staff, in relation to decisions on donor acceptance, and that a 'standard guide' should be produced based on the ESESBTS donor selection document.

**18.43** At the start of the reference period there was confidence in the ability of medical staff to identify donors presenting risk. The authors of the 1971 WHO *Guide* reflected that confidence, commenting that 'the medical officer should be able to pick out those prospective donors who may be, for example, undernourished, crippled, mentally unstable, alcoholics, or drug addicts'.<sup>55</sup> As grounds for distinguishing acceptable from unacceptable potential donors, the comments use the language of the times but apart from that they reflect, in retrospect, an unsophisticated approach to the assessment of risk. It has to be noted, however, that in 1971 general medical knowledge of the risks that later came to be identified and understood, was equally unsophisticated.

**18.44** It is unlikely that there was questioning on sensitive personal matters. Obtrusive questioning, or questioning not felt to be appropriate, could have proved unacceptable to return donors and might have threatened the core supply on which the service depended.

**18.45** Dr Mitchell's relatively extreme attitude to these matters may have emphasised the risk of upsetting donors over the risk to recipients of potentially infected blood or blood products. The lack of systematic questioning of prospective donors about hepatitis, for example, might have led to the failure to identify donors whose donations would have been rejected if true and reliable answers had been given to questions about matters indicating or suggesting high risk of transmission of infection. A focus on the

<sup>54</sup> Mrs Prior's written statement [PEN.019.0107] at 0108

<sup>55</sup> *Blood Transfusion: a Guide to the Formation and Operation of a Transfusion Service* [PEN.002.0462] at 0488

best interests of the donor panel appears to have reflected the emphasis placed by the WHO on the convenience, comfort and wishes of the donor (paragraph 18.17 above). That is understandable, at least so long as the risk to the recipient of blood reflected the view that hepatitis was generally a low-risk infection. His was one of the range of views acceptable in a context that gave high priority to the practitioner's autonomy at a period when knowledge of risk was relatively undeveloped.

**18.46** Relevant risk factors were more focused following the acceptance that AIDS probably presented a transfusion risk.<sup>56</sup> This brought a step change in the rigour of the donor selection procedures, beginning in the spring of 1983,<sup>57</sup> and in the desire to have national consistency in proper documentation of the procedures as they evolved.<sup>58</sup> However, direct oral questioning on sexual matters was not introduced even then,<sup>59</sup> although whether the incidence of transmission of hepatitis would have been reduced by more active questioning, remains speculative. It has to be borne in mind that there was no screening test for Hepatitis C until after the discovery of the virus in 1988, and until 1985 non-A, non-B Hepatitis (NANB Hepatitis) was considered to be generally benign, largely because in most cases there were few clinical signs of infection that could be identified. It is not clear that there were questions that could have been formulated that would have elicited relevant information from donors. And up-to-date methods of screening for HBV were adopted, using the technology available at the time.

### Grounds of exclusion: medical history

**18.47** As is clear from the preceding discussion, from time to time particular groups of potential donors have been perceived to present a high risk of transmitting disease. These have included people with a record of parenteral (injecting) drug abuse. In addition, people detained in penal institutions were thought to present relatively high risks. It has been suggested to the Inquiry that US servicemen were relatively high risk donors. These groups are discussed separately in Chapter 26, *Donor Selection – Higher Risk Donors*. More generally, individuals with a history of hepatitis and individuals who had at some stage received blood transfusion, whatever their status otherwise, were perceived to present an unacceptable risk. This part of the discussion deals with these general issues.

### *Exclusion on grounds of jaundice or hepatitis*

**18.48** As discussed in Chapter 25, *Screening of Donated Blood for Hepatitis B*, practice relating to exclusion on grounds of hepatitis was closely related to technological changes in screening for hepatitis in blood donations. In the absence of contemporaneous documents setting out practice guidance it is difficult to relate changes in practice to changes in technology with any degree of precision. This section seeks to identify some stages in the evolving scene and to comment particularly on blood collection practice.

**18.49** As noted already, in the period up to the early 1970s the terms 'hepatitis' and 'jaundice' were often used indiscriminately: in general understanding, infection with hepatitis was typically evidenced by the clinical symptoms and signs of jaundice. It was known that there was a risk of transmission, but there was little understanding of that

<sup>56</sup> Dr McClelland – Day 9, page 24

<sup>57</sup> See Chapter 28, *Donor Selection – AIDS*, paragraph 28.2

<sup>58</sup> Dr McClelland – Day 9, page 23

<sup>59</sup> See Chapter 28, *Donor Selection – AIDS*. In some areas leaflets, of varying specificity, were used to inform donors of potential risks.

risk or of the clinical course and effects of infection. Initially, a conservative approach was taken to donor exclusion where there was evidence of exposure to hepatitis. By the mid-1960s, prospective donors giving a history of ever having had infective hepatitis, which almost always equated with a history of having had transient jaundice, were excluded from donor panels.<sup>60</sup> At this stage, before the Hepatitis A and B viruses were identified, the practice in the UK of excluding from donation any prospective donor with a history of jaundice, appears to have been common in Western countries.

**18.50** For many prospective donors, giving an accurate history of previous jaundice would have been challenging. Jaundice in infancy, jaundice many years previously at a time of other more serious illness, anicteric hepatitis and other conditions not noted at the time would have militated against disclosure, except perhaps on detailed investigation of medical records. The interview procedures discussed above were in many cases unlikely to succeed in eliciting a relevant history. It appears very unlikely that reporting would have been significantly distorted by purported disclosure of jaundice that had not been experienced. The consequence of relying on donor recollection is more likely to have been under-reporting of jaundice and, for that reason, a flawed understanding of the risks presented. The prevalence of anicteric forms of hepatitis, and in particular of NANB Hepatitis, further hampered understanding of the risks presented by hepatitis in the widest sense.

**18.51** The 1971 WHO *Guide to the Formation and Operation of a Transfusion Service* reflected a changed understanding of risk. It pointed to the risks of transmission of a number of diseases including hepatitis. The clinical signs and symptoms of infectious and serum hepatitis as then understood were described, and it was observed that:

Patients with clinical jaundice are not the main source of the disease; far more significant sources are the mild anicteric case [that is, mild cases without overt jaundice], the convalescent carrier, those incubating the disease, and the healthy contact carrier, all of whom at one time or another may be viraemic [carry the virus in their blood].<sup>61</sup>

**18.52** At that stage, NANB Hepatitis was unknown and inferences were drawn as to the nature of risk that subsequently proved to be seriously flawed. While there began to be references to other forms of hepatitis, attention was focused on Hepatitis B and the relationship, if any, between HBV antigen or antibody positivity and a past history of jaundice. A positive test for HBsAg indicated current viraemia. However, the relevance of a history of jaundice was undermined. A WHO expert group report of 1973 observed:

Limited surveys have also shown that the prevalence of hepatitis B antigen is no higher amongst donors with a past history of jaundice than in those without such a history.<sup>62</sup>

**18.53** The 1973 report also noted that it was generally agreed that not all cases of post-transfusion hepatitis were caused by Hepatitis B infection and that 'as more hepatitis B carriers are eliminated from serving as blood donors, the proportion of cases due to other

<sup>60</sup> *The Practitioner*: No 1166 (August 1965) pp 184–5 [LIT.001.4394]

<sup>61</sup> *Blood Transfusion – A Guide to the Formation and Operation of a Transfusion Service* [PEN.002.0462] at 0481

<sup>62</sup> 'Viral Hepatitis: Report of a WHO Scientific Group', *World Health Organization Technical Report Series*, 1973, No. 512 [SGH.002.9746] at 9761

types of hepatitis will increase'.<sup>63</sup> In relation to the exclusion of donors on grounds related to hepatitis, however, it was Hepatitis B that was discussed and the report marked the beginning of a change of attitude. The 1973 report developed the discussion of risk from the position set out in the 1971 report.<sup>64</sup> Firstly, it was observed that the exclusion from blood donation of individuals with a clinical history of Hepatitis B infection, but who did not have detectable antigen, might not materially reduce the frequency of hepatitis among the recipients of blood. Secondly, it was observed that the exclusion from blood donation of those with serological evidence of previous infection with Hepatitis B, indicated by the presence of antibody, might not be justified.

**18.54** In international guidance, this was the start of a move away from excluding all donors with a history of hepatitis, towards excluding more limited groups with a relevant recent history.<sup>65</sup> Only Hepatitis B was relevant in the context of contemporaneous knowledge. The 1973 WHO report noted that the existence of a chronic carrier state following Hepatitis A (HAV) infection had not been proved.<sup>66</sup> That turned out to be correct: there is no chronic carrier state for HAV. It is now clear that most of the individuals with a history of hepatitis were carriers of NANB Hepatitis virus and could not have been identified by the tests for HBV then becoming available.

**18.55** Leaving aside HBV screening results, the restriction of exclusion criteria related to a donor's history of jaundice or hepatitis appears questionable on logical grounds. The 1973 report recognised that post-transfusion hepatitis was not solely associated with HBV: there were thought to be a variety of causes of hepatitis. It was to become known that NANB Hepatitis was not generally associated with a history of jaundice. But that was not known in 1973, and there was no exhaustive analysis of the historical antecedents of any other transmissible agent of hepatic disease. The explanation appears to be that there was a strand of belief that was prevalent up to the early 1970s that once Hepatitis B had been dealt with, the problem of Post-Transfusion Hepatitis (PTH) would be solved.

**18.56** The same approach to donor exclusion, as expressed in the WHO report, appeared in a letter from Dr John Wallace of the Glasgow and West of Scotland BTS published in the *British Medical Journal* of 11 August 1973. Dr Wallace reported the findings of a study in his region that 'volunteers with a history of jaundice or of recent contact with a case of jaundice do not have a higher incidence of positivity for [Hepatitis B antigen and antibody] than in donors lacking this history'.<sup>67</sup>

**18.57** The Advisory Group on Testing for the Presence of Australia (Hepatitis Associated) Antigen and its Antibody (the Maycock Group),<sup>68</sup> originally set up in September 1970, was re-convened on 6 December 1973.<sup>69</sup> In its second report, published in September 1975, it recommended that the practice of excluding donors with a history of jaundice should be discontinued, provided that HBsAg was not detected using a sensitive test and the donor had not suffered from hepatitis or jaundice during the previous 12 months.<sup>70</sup>

<sup>70</sup> Ibid [SGH.003.0079] at 0084

**18.58** Increased understanding of Hepatitis B had driven the change. But there was still no means of limiting the risk of transmission of other viruses causing post-transfusion hepatitis. The existence of long-incubation post-transfusion hepatitis unrelated to Hepatitis B, postulated by Dr Alfred Prince and colleagues in *The Lancet* published on 3 August 1974, was not noted in the Maycock Group's discussion of the topic of exclusion on grounds of jaundice or hepatitis history.<sup>71</sup>

**18.59** An internal DHSS memorandum dated 16 March 1976 noted that some RTDs in England and Wales 'express[ed] reservations about discontinuing (within prescribed safeguards) the practice of excluding from the panel donors with a history of jaundice but the majority favour admitting such donors from a given date'.<sup>72</sup> That became established advice.<sup>73</sup>

**18.60** Consistent advice was published by the WHO in 1975. Recommendations included:

6 At present blood donors should not be excluded on the evidence of previous hepatitis alone, whether it is based on a past history of infection or on the findings of hepatitis B surface antibody, provided that they have had no attack of hepatitis during the previous year and their blood has been found negative for hepatitis B surface antigen by a very sensitive test.

7 There can be no categorical designation of high risk blood donor groups; the situation is likely to vary from country to country from time to time and within countries. Any subpopulation with specific characteristics shown to have a continuing carrier rate of HBsAg at least three times that of the total potential blood donor population may be considered for exclusion. However, such decisions should be made on a local basis with due regard to the needs and availability of blood.<sup>74</sup>

**18.61** Dr McClelland said that paragraph 7 of the WHO report was relevant to the question of taking blood from donors in Scotland.<sup>75</sup> The advice was probably a reflection of the growing awareness at the time of the variability of the prevalence of Hepatitis B surface antigen carriage in the populations of different countries. But it was relevant to the assessment of the suitability of any population.

**18.62** The three WHO papers referred to reflected developments in opinion that coincided, in time, with growing knowledge of the hepatitis viruses and with the development of HBsAg assays. It would be unrealistic, however, to think that this increased knowledge would lead to the rapid production of new assays, or to the instant adoption of tests as they became available. In 1972, Dr Wallace commented:

The phenomenon of a long latent period between significant experimental observations and their application in clinical practice is not confined to blood transfusion. Part of the delay is caused by the need to develop new technical

<sup>71</sup> Prince et al, 'Long-incubation post-transfusion hepatitis without serological evidence of exposure to hepatitis-B virus', *The Lancet*, 1974; 241 [LIT.001.0363]. Professor Cash explained that 'I saw Alfred Prince in my 1969 visit to the States, he gave me a small vial of Australia antigen in New York and I brought it back, and that was the first beginnings of testing for Australia antigen, certainly in Scotland. This was an outstanding group'. Day 10, page 101

<sup>72</sup> Memorandum from TE Dutton to Dr Waiter dated 16 March 1976 at para 4, item 104A [SGF.001.2841] at 2842. South West Thames Regional Health Authority were also noted to have 'Reservations about including or readmitting donors with a history of jaundice' (para 4, item 102A).

<sup>73</sup> See Chapter 25, *Screening of Donated Blood for Hepatitis B*, paragraphs 25.38–25.39

<sup>75</sup> Dr McClelland – Day 9, page 111

capabilities, and by having to await adequate financial support. Even more important is a human reluctance to depart from the familiarity of old habits and a natural suspicion of things new. In some respects progress in blood transfusion is being retarded because new ideas are not easy to sell to old heads.<sup>76</sup>

**18.63** General advice was developed in 1976 with the publication of the International Society of Blood Transfusion (ISBT) Guide *Criteria for the Selection of Blood Donors*.<sup>77</sup> Some of the guidance is relevant to later topics, but it is helpful to note the full range at this point, since it emphasised the need for general precautions notwithstanding developments in screening. In this respect the Guide marked a significant development in re-assessing general exclusion policy and practice. The Guide stated:

In spite of recently developed tests for the detection of HBsAg, only a relatively small proportion of carriers can presently be detected. No routine screening test is presently available for the detection of hepatitis A virus, or of other viral agents that cause transfusion-associated hepatitis. It follows, therefore, that some general precautions should be taken in an attempt to reduce the risk of such viral agents being transmitted from donor to recipient.

Prospective donors should be excluded if it is known that they:

1. Give a history of viral hepatitis at any time, except during the first months of life ...
2. Have received a transfusion of blood or blood products within the last six months.
3. Have been in close, household contact with a case of “infectious hepatitis” in the last six months.
4. Have donated blood which was strongly suspected of having been responsible for a case of post-transfusion hepatitis.
5. Are suspected to be parenteral drug addicts.
6. Have been tattooed, had their ears pierced, or experienced acupuncture within the past six months.
7. Are inmates of a correctional institution.
8. Are HBsAg positive.
9. Are working in high-risk areas such as haemodialysis centres.<sup>78</sup>

**18.64** The 1977 NBTS *Memorandum on the Selection of Donors* provided for exclusion in the same terms as items 2 and 3 of the ISBT Guide. Item 1 was not followed. The *Memorandum* reflected the advice of the Maycock Group and stated that those with a history of jaundice or hepatitis could be accepted as donors provided they had not suffered from jaundice or hepatitis in the previous 12 months and provided they tested negative for Hepatitis B surface antigen using a sensitive test (RPHA or RIA). Item 8 was reflected in a positive stipulation that an accepted test for HBsAg be performed each time

<sup>76</sup> Wallace, ‘New approaches to the supply of blood and plasma’, *Proceedings of the Royal Society of Edinburgh*, Section B (Biology) 1972; vol 71: Supplement: S.13 [PEN.018.1026] at 1032

<sup>77</sup> *Criteria for the Selection of Blood Donors* [DHF.001.2672]

<sup>78</sup> *Ibid* [DHF.001.2672] at 2683

a donor was bled, and that donors whose blood reacted positively should be excluded permanently from the donor panel.<sup>79</sup>

**18.65** In his evidence to the Inquiry, Dr McClelland stated that he believed that the SNBTS adopted a similar approach to the acceptance of donors with a history of jaundice as that set out in the 1977 NBTS *Memorandum*, albeit that some regions may have restricted acceptance to cases where the donor had only experienced jaundice before the age of 12 years.<sup>80</sup>

**18.66** The pattern of infection in Scotland was a factor underlying changes introduced to the 1977 guidance.<sup>81</sup> The restriction on accepting donors with a history of jaundice was relaxed in the case of donors infected under the age of 12 years because, where there was evidence of infection, it was almost always found to be an antibody to HAV. Dr McClelland thought that this was based on work done by Dr Brian Dow in Glasgow, who reported that many patients who had jaundice in childhood had been infected with Hepatitis A, a transient infection which was for all practical purposes considered not to be transmissible by transfusion. He suspected that the decision to restrict the acceptance of a donor with a jaundice history in later life was related to concern that jaundice occurring later might not be due to Hepatitis A, but due to NANB Hepatitis.<sup>82</sup>

**18.67** Dr Wallace's book, *Blood Transfusion for Clinicians*, was published in 1977. It noted, without criticism, the 1975 WHO recommendation that volunteers with a history of clinical hepatitis could be accepted as donors provided the clinical illness occurred more than 12 months previously, and the serum of the donor was shown not to contain HBsAg when tested by a sensitive method.<sup>83</sup>

**18.68** The topic continued to generate study and correspondence in professional publications. In October 1978, Renton and others, of the Manchester BTS, reported their findings on whether the inclusion of donors with a history of jaundice had led to an increased incidence of HBsAg positive tests.<sup>84</sup> Donors with a history of jaundice were 3.5 times as likely to be HBsAg positive as donors without such a history. The sensitivity of the test influenced their conclusion:

[T]he rate of HBsAg positives amongst these people is still small, and with the sensitive tests at present in use we do not believe that these figures mean that such donors ought to be excluded from the panels.

**18.69** Despite that, it was a challenge to the accepted understanding. Contrary views were also expressed. On 21 July 1979, *The Lancet* published a letter from Dr Robert Crawford and colleagues at the Glasgow and West of Scotland BTS reporting on their study into blood donors with a history of jaundice. The authors found that a history of jaundice was not materially higher in donors who tested positive for HBsAg than in those who did not. They stated:

<sup>79</sup> 1977 *Memorandum* [SNB.002.5348] at 5350. A similar provision was contained in the 1983 *Memorandum* ([SGF.001.0377] at 0388), the 1985 *Memorandum* ([DHF.001.8931] at 8943) and the 1987 *Memorandum* ([SNB.006.6410] at 6418)]. For completeness, it is noted that the *Standards for the Collection and Processing of Blood and Blood Components and the Manufacture of Associated Sterile Fluids*, published by the DHSS in 1979, stated that, 'The following diseases may lead to acceptance, deferment or disqualification as donors ... jaundice or hepatitis in the last year' [PEN.002.0249] at 0253.

<sup>80</sup> Dr McClelland – Day 9, pages 90–91

<sup>81</sup> *Ibid* pages 91–92

<sup>82</sup> *Ibid* pages 90–92

<sup>83</sup> Wallace, *Blood Transfusion for Clinicians*, 1977 [LIT.001.3058] at 3107

<sup>84</sup> Renton et al, 'Blood donors with a history of jaundice', *The Lancet*, 1978:833 [PEN.002.0851]

We conclude from these results that a history of jaundice does not materially increase the prevalence of HBsAg among blood-donors and is likely to imply previous infection with [Hepatitis A virus] rather than with [Hepatitis B virus].<sup>85</sup>

**18.70** The findings of the Glasgow BTS study were reported more fully in *The Lancet* on 2 February 1980. The authors stated:

The findings suggest that in a country with a low incidence of hepatitis-B carriage a history of jaundice is much more likely to equate with prior hepatitis-A infection than B infection. There is no evidence to support the practice of regarding blood donors or patients with a history of jaundice as a special group with more prior exposure to hepatitis B virus and thus more likelihood of being long-term carriers of hepatitis-B virus.<sup>86</sup>

**18.71** On 15 March 1980, *The Lancet* published a letter from Dr Robert Hopkins and colleagues at the ESESBTS on the topic of blood donors with a history of jaundice. The letter stated:

The former policy of the Scottish Blood Transfusion Service was to reject as donors all persons admitting a history of jaundice. Lately this policy has been modified to exclude only would-be donors with a history of jaundice within the previous twelve months: donations are now accepted from most persons with a history of jaundice, provided they are HBsAg negative upon routine testing.<sup>87</sup>

**18.72** After reporting the findings of their study the authors stated:

We conclude that in the donor population of South-East Scotland a history of jaundice is not associated with an increased risk of HBsAg carriage. This is in agreement with findings in the West of Scotland reported by Dr Follett and colleagues. The prevalence of antibody to hepatitis A in our region is similar in donors with and without a history of jaundice (84% and 78%). This suggests that the viruses of "non-A, non-B hepatitis" may be a significant cause of jaundice in this population.<sup>88</sup>

**18.73** This too was controversial. In his evidence to the Inquiry, Dr Dow stated that the finding in the Edinburgh study of a similar incidence of Hepatitis A in donors with a history of jaundice and in donors without such a history, was at variance with the findings in the west of Scotland where the incidence of Hepatitis A was much higher in donors with a history of jaundice. Dr Dow considered that one would need to know how many donors were tested in the Edinburgh study and considered that the suggestion in the last sentence about NANB Hepatitis was 'pure speculation'.<sup>89</sup>

**18.74** On 23 October 1982, the *British Medical Journal* published a letter by Mr Archie Barr and colleagues at the Glasgow BTS on the topic of blood donors with a history of jaundice. They reported:

We have now studied a group of donors according to the age at which the jaundice occurred. Almost all the episodes of jaundice occurring before the age of 13 years were due to hepatitis A infection, but about 20% of those

<sup>85</sup> Crawford et al, 'Blood donors with a history of jaundice', *The Lancet*, 1979:155 [LIT.001.2155]

<sup>88</sup> Ibid [LIT.001.0429]

<sup>89</sup> Day 24, page 149

with jaundice in adolescence or later had no markers for hepatitis A or B. Other viruses can cause jaundice – for example, Epstein-Barr virus, cytomegalovirus, Coxsackie virus, adenovirus – and many other agents can cause liver problems. We cannot, therefore, equate unexplained jaundice with infection by the elusive non-A, non-B viruses. Indeed, it is uncertain whether sporadic non-A, non-B hepatitis is caused by the same agent as the form of the disease transmitted by transfusion, and it is not known how often a carrier state follows sporadic infection. Furthermore, it is possible that, as with hepatitis B, clinical jaundice may be an indicator of elimination of virus rather than carriage ....

In the last three years this region has transfused nearly 400,000 donations of blood and their derivatives. Only 12 cases of overt post-transfusion hepatitis possibly attributable to non-A, non-B agents have been notified .... None of the donors involved in the eight cases associated with red-cell transfusion had given a history of jaundice ....

The present British policy appears to be correct, and any change could cause a serious loss of blood products when some regions are still struggling to make 80% of the blood plasma they collect available for factor VIII production ....<sup>90</sup>

**18.75** In May 1986, Dr Dow presented a Special Report to the SNBTS Directors on Surrogate Tests for Non-A, Non-B Hepatitis. The report noted that:

In the USA individuals with a history of prior jaundice are excluded because of the possibility of their jaundice episode being due to NANB and subsequently becoming chronic carriers of NANB agent(s). Exclusion of such individuals in the West of Scotland population would incur a loss of around 2 to 3% of donors.<sup>91</sup>

**18.76** After commenting on the three NANB Hepatitis surrogate screening tests then under consideration, namely, excluding donors who had a history of jaundice, who were positive for antibodies to the Hepatitis B core antigen or who had an elevation of the liver enzyme ALT, the report stated:

The effect of these strategies in identifying implicated donors involved in NANB PTH cases.

The “acid” test for either of these three means of identifying potential NANB carrier donors is to examine the effect, if any, they would have in identifying such donors amongst those implicated in reported cases of NANB PTH.

Of the 65 donors implicated in 18 NANB PTH cases, only 2 had histories of jaundice and both were involved in the cases in which jaundice may have been caused by the effects of drugs rather than transfused blood.<sup>92</sup>

**18.77** The report concluded:

The present UK policy of accepting donors with raised ALT levels .... anti-HBc or histories of jaundice would appear to be correct. It would appear from the study that the introduction of such surrogate screening procedures would have

<sup>90</sup> Barr et al, ‘Blood donors with a history of jaundice’, *British Medical Journal*, 1952:285 [PEN.014.0067]

<sup>91</sup> Surrogate Tests for Non-A – Non-B Hepatitis – Special Report to Regional Transfusion Directors [SNF.001.1109]

<sup>92</sup> Ibid [SNF.001.1109] at 1110.

little impact on reducing the already low level of NANB PTH cases at present reported within the West of Scotland region.<sup>93</sup>

**18.78** Continuing controversy over these matters clouds the issue as to whether interview practices in the 1970s and early 1980s were likely to provide relevant and reliable information about the risk that an individual prospective donor's blood might be infective for Hepatitis B, or any other transmissible infection. As some of the evidence shows, the debate tended to move from Hepatitis B to NANB Hepatitis over this period. There was no test for any NANB Hepatitis virus before 1988. The use of surrogate testing in that context is discussed in Chapter 27, *Surrogate testing of Donated Blood for Non-A, Non-B Hepatitis*.

**18.79** In November 1987 the NBTS advice was modified.<sup>94</sup> Donors reporting jaundice or hepatitis in childhood followed by full recovery were to be accepted. Item 1 of the ISBT guidance was now reflected in the NBTS advice. Donors reporting adult jaundice or hepatitis were to be deferred pending additional information from their general practitioners. If it proved not to be Hepatitis B, they were to be accepted one year after full recovery. Donors known to have had Hepatitis B and who wished to donate were to be referred to their NBTS Centre for individual consideration. Hepatitis contacts were to be deferred for six months after close contact. It was recognised that defining high risk donor populations by means of fixed HBsAG prevalence rates could cause problems, and that it was necessary to have regard to the impact of guidance on the availability of blood supplies.<sup>95</sup> This was consistent with the Maycock report,<sup>96</sup> and in turn with the 1977 guidance.<sup>97</sup> That version of the NBTS *Memorandum on the Selection, Medical Examination and Care of Blood Donors* (1977) embodied the Maycock recommendation on exclusion. There was a change towards accepting donors with a history of jaundice or hepatitis, as long as the attack had been more than 12 months previously and the donor was proven negative for Hepatitis B surface antigen using a sensitive test.

**18.80** The progressive reduction in the range of individuals excluded would probably have improved to some extent the prospects of obtaining relevant information on interviewing potential blood donors. More recent episodes of hepatitis, particularly involving jaundice, would have been likely to have been recalled by donors. A person who had had no overt signs or symptoms of infection might be wholly unaware of his or her infection but, where there was a known infection, disclosure still depended on the ability and willingness of the individual presenting as a donor to provide a history. Some donor sessions, in factories or other work places and in public places such as shopping centres, were less than private, and a donor might prefer to conceal a relevant fact rather than explain to colleagues why no donation had been taken.

### ***Exclusion on the ground's of NANB Hepatitis and jaundice***

**18.81** Developing knowledge of NANB Hepatitis and the development of tests indicative of infection with that disease are dealt with in detail elsewhere. For the purposes of this discussion, the question is whether the interview techniques, focussed as they were

<sup>93</sup> Ibid [SNF.001.1109] at 1111. Dr Dow's research and the error inherent in the approach of relying on reported cases of post-transfusion jaundice to estimate the prevalence of post-transfusion NANB Hepatitis are more fully discussed in this Report in the chapter on surrogate testing.

<sup>94</sup> *Guidance for the Selection, Medical Examination and Care of Blood Donors* 1987 [SNB.006.6410] at 6418

<sup>95</sup> Dr McClelland – Day 9, page 111

<sup>96</sup> Second Report of the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen and its Antibody [SGH.003.0079]

<sup>97</sup> Dr McClelland – Day 9, page 110; *Memorandum on the Selection, Medical Examination and Care of Blood Donors* – Section 1 – Selection of Donors [SNB.002.5348]

on prior hepatitis and in particular on the signs of jaundice, were effective means of identifying potential donors infected with the NANB Hepatitis virus, as an incidental result of exploring the potential donor's exposure to HBV.

**18.82** The letter by Dr Hopkins and colleagues, referred to at paragraph 18.71 above, suggested an association of jaundice and the NANB Hepatitis/Hepatitis C (HCV) viruses. Dr Dow thought that was speculative. Mr Barr and colleagues considered that one could not associate unexplained jaundice with 'the elusive non-A, non-B viruses'. Dr Dow and colleagues thought that using histories of jaundice would have little impact on reducing NANB PTH cases. Two sources of evidence deal conclusively with the issue.

**18.83** In his written evidence to the Inquiry, Dr McClelland stated:

With respect to antibody to hepatitis C virus, Crawford et al 1994,<sup>98</sup> found that only 5.9% of the donors who had been found to be HCV positive gave a history of jaundice, suggesting that the result of this questioning would not be an effective screening test. This is consistent with observations that the natural history of hepatitis C infection does not typically include early episodes of jaundice. The infection can be asymptomatic for a long period after exposure, so it cannot be assumed that donors carrying the virus would recall any episode of jaundice or hepatitis ....

I am unable to estimate the size of any possible impact of an exclusion of donors with a history of jaundice on the incidence of post transfusion hepatitis, but I think it is unlikely that any effect would have been large.<sup>99</sup>

**18.84** Professor Juhani Leikola gave the following evidence:

On the basis of what was known at the time, in my opinion it was a reasonable policy to accept otherwise healthy individuals (after a quarantine time) but who gave a history of jaundice. In the past it was natural to think that the cause of jaundice would have been hepatitis A (after recovery blood is not infectious) since hepatitis B would have been detected in the laboratory. However, once it became clear by mid-1970s ... that after clinical hepatitis B the patient may become chronic carrier of the virus with HBsAg levels below detection limits and that there could be another hepatitis virus causing first jaundice and chronic carrier state without clinical symptoms, the policy could have been reconsidered. However, I think that precluding all donors giving a history of jaundice would not have had a major effect on the blood transfusion safety.<sup>100</sup>

**18.85** Professor Leikola was asked why the exclusion of donors with a history of jaundice was unlikely to have had a major effect on blood transfusion safety. He replied:

What we know about these diseases right now is that the vast majority of the carriers of either Hepatitis B or Hepatitis C virus, they have not had any jaundiced phase in their disease. The vast majority is really subclinical and maybe not causing any symptoms at all. On the other hand, some people with acute infectious hepatitis, especially Hepatitis A, they recover completely from

<sup>98</sup> Crawford et al, 'Prevalence and epidemiological characteristics of hepatitis C in Scottish blood donors', *Transfusion Medicine*, 1994; 4:121–124 [PEN.002.0582]

<sup>99</sup> Dr McClelland's written statement, [WIT.003.0072] at 0089

<sup>100</sup> Professor Leikola's written statement, [WIT.003.0027] at 0030

that jaundice and they are not hazardous to the blood transfusion matter. So in light of what we know now, I don't think that precluding people giving a history of jaundice would have very much influenced the final blood safety.<sup>101</sup>

**18.86** From what is now known, it seems unlikely that the practice of accepting donors with a history of jaundice did materially increase the risk of recipients developing post-transfusion NANB Hepatitis/HCV. Firstly, the vast majority of donors with a history of jaundice were likely to have been jaundiced as a result of causes other than Hepatitis C, for example:

- Hepatitis A (from which donors will have long since recovered and which is generally not transmissible by blood).
- Hepatitis B (in respect of which any donors carrying the antigen at the time of donation are likely to have been detected by the Hepatitis B screening tests and excluded).
- Non-hepatitis viruses (such as cytomegalovirus or Epstein Barr virus).
- Non-viral causes (including alcoholic liver disease, gallstones, and adverse reaction to medication).<sup>102</sup>

Secondly, only a small proportion of individuals who contract Hepatitis C develop jaundice, with the result that most donors with Hepatitis C would not have been excluded by a policy that excluded donors with a history of jaundice.<sup>103</sup> Thirdly, it appears that individuals who contract Hepatitis C and who have an acute episode of jaundice, are more likely to clear the virus, and no longer be infective, than individuals who contract Hepatitis C and who do not experience an acute episode of jaundice.<sup>104</sup>

**18.87** On the basis of what was known at the time, and in light of the recommendations contained in the 1975 WHO report and the second report of the Maycock Advisory Group, it seems reasonable for the Scottish Blood Transfusion Service, from around the mid-1970s, to have accepted donors with a history of jaundice and who were negative for HBsAg. Indeed, no suggestion to the contrary was made to or by any of the witnesses at the Inquiry. The policy of the SNBTS from around the middle of the 1970s to accept donors with a history of jaundice (and who tested negative for HBsAg) appears unlikely to have materially increased the risk of transfusion-transmitted Hepatitis C.

**18.88** Shortcomings in collection procedures, and in particular interview techniques, cannot be said to have had any material bearing on the outcome for recipients of blood products so far as NANB Hepatitis is concerned. There were no known signs and symptoms of infection that could have been elicited by interview of the potential donor, and the information that may have been elicited pointing to a history of Hepatitis B infection would not have alerted the transfusion service to the possibility of infection with NANB Hepatitis.

<sup>101</sup> Professor Leikola – Day 13, page 87

<sup>102</sup> Dr Dow – Day 24, Pages 161–162

<sup>103</sup> In his evidence to the Inquiry, for example, Dr Gillon stated that he had looked at the literature and, while it is very difficult to get a figure, 'It is a very small figure and I think most authorities accept that jaundice is an occasional but rare feature in non-A non-B hepatitis': Day 11, pages 15–16

<sup>104</sup> Professor Thomas – Day 52, page 69

### *Previous transfusion*

**18.89** A prospective donor who had previously had a transfusion of blood or blood components, or who had been treated with blood products, might have acquired disease on that occasion, transmitted by the blood from the original donor, and that was considered to be a risk leading to exclusion, at least within certain time limits.<sup>105</sup> The risk of that person transmitting infection was the same, however the donor of the source blood came to be infected.

**18.90** Item 2 in the section of the 1976 ISBT *Criteria for the Selection of Blood Donors* quoted in paragraph 18.63 above had provided for exclusion where the transfusion had been received within the previous six months.<sup>106</sup>

**18.91** In 1978 the WHO Expert Committee on Biological Standardization published a report.<sup>107</sup> The report noted that it had been agreed that it would be useful to have a single set of requirements applicable to all organisations and laboratories involved in the collection or fractionation of blood and blood products. The report included an Annex on Requirements for the Collection, Processing and Quality Control of Human Blood and Blood Products.<sup>108</sup> In respect of the medical history of donors and, in particular, infectious diseases, the report contained a similar recommendation to the ISBT *Guide*:

Donors shall have a negative history ... of receipt within six months of human blood or any blood component or fraction that might be a source of transmission of viral hepatitis.<sup>109</sup>

**18.92** The Memorandum on the Selection, Medical Examination and Care of Blood Donors, produced by the Transfusion Directors in England and Wales stated, since at least 1977, that donors should be temporarily deferred who, within the last six months, had either undergone a transfusion with blood or plasma or had undergone acupuncture or ear piercing.<sup>110</sup>

**18.93** As noted at paragraph 18.25 above, the 1979 edition of the *Standards for the Collection and Processing of Blood etc* stated that transfusion within the last six months should result in temporary deferment.<sup>111</sup>

**18.94** Two factors changed the context for exclusion on the grounds of prior transfusion. The first was an appreciation of the risks associated with AIDS, which brought about material changes in procedures in about 1983. These changes are dealt with in Chapter 28, *Donor Selection – AIDS*.

<sup>109</sup> *Ibid* [LIT.001.3627] at 3651. As regards the last recommendation quoted, relating to the avoidance of donor population showing a higher prevalence of acute or chronic hepatitis than in the general population, Professor Leikola explained in his evidence to the Inquiry that he would not place much weight on that recommendation because direct markers of disease (eg the presence of antigen) should be used when identifying a group with a higher prevalence of disease rather than indirect markers such as ‘acute or chronic hepatitis’; the recommendation does not say how much higher the prevalence of disease should be in a donor group for that group to be excluded and the committee who produced the recommendation comprised biologists, virologists and fractionators rather than those with practical experience of blood collection or transfusion: Day 13, pages 57-58

**18.95** The second was the risk posed by variant CJD. In current practice, individuals who might have received a blood transfusion since 1980 are not accepted as donors.<sup>112</sup> That decision was taken in 2004 when the first documented clinical case of transmission of variant CJD by a red cell component was described.<sup>113</sup> The intention was to avoid the risk that individuals who themselves had variant CJD through a blood transfusion, might carry on donating and continue recycling the infection in the community. The decision excluded about 3.5% of the donor population at that time (2004), and a higher percentage of the blood donated because people who themselves had received blood transfusions in the past, or whose relatives had benefited from transfusion, were often very keen to contribute something to the community, so that they were often amongst the most dedicated donors. The Services may defer about 1% of donors on this ground on an ongoing basis.<sup>114</sup> As some people do not know whether they have been transfused, if it is inferred from other history that they probably have been transfused they will then be excluded on a precautionary basis.

### Comment

**18.96** The general policy of voluntary donation at the beginning of the period put emphasis on the exclusion of particular groups of potential donors, permanently or temporarily, from donating blood for clinical or therapeutic application as a means of limiting risk. The five regions of the SNBTS drew on the *Standards* and the 1977 *Memorandum on the Selection, Medical Examination and Care of Blood Donors*, as updated, and were involved in the development of the 1989 *UK Professional Guidelines for the Care and Selection of Blood Donors*. Until the advent of AIDS the questioning of donors was less rigorous, being both less direct and less personal. There were also differences of approach apparent between the Regional Centres in relation to donor selection as reported by Dr Gillon in 1985. As late as the early 1980s, a form in use in Glasgow and the West of Scotland identified certain infectious diseases and asked whether the individual had had contact with or had recently recovered from any of them; identified other serious illnesses and asked whether the individual had had such an illness. It also asked whether the individual had had inoculations, surgery or had worked or taken part in sports involving unusual hazards. It did not refer to drug abuse or any aspect of sexual orientation or behaviour.<sup>115</sup>

**18.97** Inhibitions on discussion of the previous medical history of the prospective donor affected the group of individuals that had received previous transfusions, as it did those with a history of jaundice. There were similar problems of recollection. Perinatal transfusion (that is, transfusion in the period immediately after birth, generally up to four weeks) is unlikely to have been known to the recipient. Some patients would never have known that they had been transfused in later life, or understood that the procedures they observed and recollected were transfusions of blood components, for example. If there was jaundice, all of the previous factors would have applied. If the hepatitis was NANB Hepatitis and there was no jaundice, there may have been no other sign or symptom to alert the individual to the need to disclose the event. By comparison, in current practice, questioning is more rigorous, and testing procedures reinforce the safety of the supply.

<sup>112</sup> Professor Turner – Day 7, page 17

<sup>113</sup> Ibid page 18. Professor Turner's evidence included a detailed explanation of modes of transmission. The 'infective agent' of vCJD, a prion protein, is not removed from blood by the conventional methods used to remove viruses, including HCV and HIV.

<sup>114</sup> Professor Turner – Day 7, Pages 19–20

<sup>115</sup> Glasgow & West of Scotland Blood Transfusion Service Questionnaire (1983) [PEN.013.1395]

**18.98** In reality, there were few if any known clinical signs and symptoms of infection with NANB Hepatitis/Hepatitis C that could have been elicited on interview of a prospective donor. Indeed, until a late stage in the development of disease there were a few clinical signs that could have been found by a competent physician on discussion with the individual. Developments in knowledge to the mid-1980s are discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*. Until the end of that period there were substantial deficits in knowledge of the disease and its natural history.<sup>116</sup> Few of the patients studied in the period had any specific symptoms.<sup>117</sup> In the event, whatever deficits may have existed in the interview procedure, it is unlikely that they had any material impact on the transmission of the infections with which this Inquiry is concerned.

**18.99** Infected blood entered the system up to the mid-1980s primarily because screening of blood for virus infection was ineffective and not because of poor interviewing practices, or donor routines. Screening was recognised as essential to the safety of transfusion, but methods developed up to that time could not identify the main causes of post-transfusion hepatitis efficiently (in the case of Hepatitis B until the late 1970s) or at all (in the case of Hepatitis C).

**18.100** In summary, and having regard to earlier discussion of developing knowledge of NANB Hepatitis/HCV, considerations that had a bearing on the development and application of policies and practices relating to the collection of blood included the following:

- The voluntary principle acknowledged a long-held view that freely donated blood presented a lower level of risk of transmitting infection than blood collected commercially from paid donors.
- Voluntary donors performed a valuable service to society.
- Mutual trust was implicit in the voluntary principle, imposing on the transfusion services obligations of care towards donors, for their safety, and more particularly for present purposes for their general well-being in the course of management of donation procedures; and imposing on donors obligations of care for the ultimate recipients of donated blood.
- The emphasis on jaundice in determining the suitability of a donor to give blood for clinical use was generally irrelevant to the risk of transmission of NANB Hepatitis/Hepatitis C, but that was not understood until the prevalence of anicteric HCV infection began to be appreciated after the introduction of anti-HCV screening in the early 1990s.
- So far as a risk of transmission of NANB Hepatitis was understood to exist, until the second half of the 1980s the disease was generally understood to be benign in its progression.
- A donor's infection with NANB Hepatitis could not have been discovered by interview: medical knowledge did not provide a basis for relevant questioning.

<sup>116</sup> Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*, paragraph 15.166

<sup>117</sup> *Ibid* paragraph 15.164

## Conclusions

- By the spring of 1983 it was accepted that AIDS presented a transfusion risk. This resulted in a step change in the rigour of donor selection procedures. Until then it is unlikely that generally recognised interview procedures at donation collections in Scotland were fully effective to elicit information about social or medical histories of donors in general which was relevant to risks of transmission of viral hepatitis.
- The emphasis on Hepatitis B reflected generally accepted views among medical experts until the end of the 1970s that HBV infection presented the most significant risk of transfusion-related transmission of viral hepatitis.
- Even after Regional Transfusion Directors introduced more rigorous interview practices in and after 1983, there were no procedures that could have elicited information indicative of asymptomatic NANB Hepatitis infection.
- Until the second half of the 1980s, NANB Hepatitis was generally understood to pose a lower risk to the recipient of an infected donation, than the underlying cause of medical or surgical treatment giving rise to the transfusion.
- Ignoring later scientific developments, so far as general members of the public offering blood donation were concerned, there was no method of identifying with interview those potential donors who were infected with NANB Hepatitis, but who remained asymptomatic at the donor session. No such interview could have been conceived at the time.

## CHAPTER 19

### PRODUCTION OF BLOOD PRODUCTS – FACILITIES

#### Introduction

**19.1** This chapter deals with the provision of facilities for the production of blood components and blood products, and in particular with the assumptions made as to process capacity in the development of plans for capital projects in the 1970s.

#### Origins

**19.2** As noted in Chapter 17, *Blood and Blood Products Management*, large-scale production of blood products in Scotland started with government-led initiatives in the 1940s leading to the establishment of facilities, first, for the preparation and storage of plasma to secure supplies to hospitals and the military, and then for the preparation of freeze-dried human plasma. The most significant developments were:

- The establishment of blood banks in the principal centres of population.
- The setting up of regional centres in Dundee, Edinburgh, Glasgow, Aberdeen and Inverness.
- The organisation of plasma filtration units in Edinburgh and Glasgow to process raw material collected locally and from other regions of Scotland.
- The installation of a Blood Products Unit (BPU) for the production of dried plasma in Edinburgh at the beginning of 1943, to meet all Scottish needs.
- The provision of a 'saline infusion fluids centre' for the preparation of saline glucose and other solutions used for intravenous injection at Glasgow, later relocated to Law Hospital, Carluke.

**19.3** The wartime facilities at the Royal Infirmary of Edinburgh (RIE) rapidly became overcrowded and unsuitable, and the centre was developed and expanded throughout the late 1940s and early 1950s, with new premises located at the RIE being opened in 1950. The BPU there began to produce a range of fractionated plasma products, beginning in 1952 with immunoglobulin and an early version of Factor VIII (Cohn Fraction I).<sup>1</sup> Despite a major reconstruction and extension of the centre in 1961 the facilities soon proved to be insufficient for the expanding operation. By early 1965, planning for a new centre (to become the new Protein Fractionation Centre (PFC) at Liberton, Edinburgh) was under discussion at government level.

**19.4** By the beginning of the reference period, the scope of the operations planned for the new PFC had changed considerably from anything that could have been envisaged in 1941, largely in response to changing demand for blood products. Cryoprecipitate had become a mainstay of haemophilia therapy, and factor concentrates were beginning to have an impact on the market. Two facilities were established in England, the Blood Products Laboratory, Elstree, (BPL) and the Plasma Fractionation Laboratory, Oxford (PFL). Planning for the Scottish facility proved to be a tortuous process, most aspects of which are of little relevance to the Inquiry. There are, however, a few matters that were important

---

<sup>1</sup> Foster, 'Plasma fractionation in Scotland', *Blood Letter*, Spring 2008 [PEN.017.2468]

when planning was completed and the construction and commissioning of the plant began.

**19.5** Two of those matters were the planned territorial scope of the PFC's operations, and the production volume targets for which the facility was to be designed. From the beginning there appears to have been uncertainty about both. It appears that from the outset the premises at the PFC, as designed, were more than large enough to accommodate a production plant sufficient to service local Scottish demand well into the 1980s. How that came about is less than completely clear. But it was to have a major impact on the ability of Scotland to meet demand for factor concentrates in this country as compared with the capacity of the BPL and the PFL to service demand in England and Wales.

**19.6** By February 1965 planning for a new centre was being discussed at meetings between the Scottish Home and Health Department (SHHD) and the Blood Transfusion Services of England and Wales and of Scotland.<sup>2</sup> It was initially estimated that the new facility required in Scotland to manufacture plasma products should be capable of processing up to 1000 litres of plasma per week, including plasma from England.<sup>3</sup> It appears that demand from Northern Ireland was to be serviced from Scotland.<sup>4</sup> Processing of plasma from England reflected a decision that would have required continuing cooperation between the Blood Transfusion Service in England and Wales on the one hand and in Scotland on the other, while managed by separate administrative agencies and subject to policy direction by separate government departments. On a practical level, it implied that a manufacturing capacity of 1000 litres of plasma per week was specified so that it would be sufficient to service demand in Scotland, Northern Ireland and in a northern part of England that still had to be defined.

**19.7** The projected capacity of the Scottish facility was amended in discussion. In May 1968, at a meeting at the RIE between SHHD, the Department of Health and Social Security (DHSS) and the Blood Transfusion Services of England and Wales and of Scotland it was anticipated that the PFC would be commissioned in June 1972 with an initial capacity of 1500 litres of plasma per week but capable of being increased to 3000 litres per week.<sup>5</sup> It was agreed that the PFC should be prepared to cope with the requirements of a larger part of England than originally intended. It was agreed that requirements for labile coagulation products (concentrates) needed to be revised.

**19.8** At a meeting in November 1968, at the BPL, between the SHHD and the Blood Transfusion Services, it was noted that approval in principle had been given for the new PFC.<sup>6</sup> It was also noted that commissioning of the new BPL extension was expected to be completed by mid-1971. It was anticipated that commissioning of the PFC would be completed early in 1973. It was hoped to start building the extension at the BPL in September 1969 with commissioning expected early in 1972. Procurement of the new centre was eventually approved in November 1969. Meantime, a new pilot plant for fractionation was established at the BPU at the RIE in 1968.<sup>7</sup>

<sup>7</sup> Maj. Gen. Jeffrey's letter of 6 January 1975 to Chief Administrative Medical Officers [SGH.007.7009]

**19.9** At a meeting on 14 March 1969, attended by representatives of the SHHD, the BPL, and the Scottish National Blood Transfusion Service (SNBTS), the need for standing arrangements for coordinating policy matters at departmental level was discussed, and a committee structure was proposed.<sup>8</sup> It was agreed that the SHHD should contact the DHSS with proposals to form a coordinating committee. The Medical Research Council (MRC) had a reference laboratory at Elstree, and might be involved in any new standing arrangements. Cooperation on professional and technical matters was expected to continue throughout the service, but within a formal relationship with the proposed coordinating committee. At this stage, it was agreed that the BPL should process two thirds of the plasma collected from England and Wales with the remainder being processed in Scotland.

**19.10** On 27 June 1969, a meeting took place at the BPL between the SHHD and the Blood Transfusion Services of England and Wales and of Scotland.<sup>9</sup> The discussion was largely confined to technology. Total production targets were not resolved. On the basis of the information available, it would be difficult to form the view that the planning of production was firmly established, on a UK or on a Scottish basis at this stage.

**19.11** In April 1970 the BPU was renamed the Scottish Protein Fractionation Centre (PFC). Mr John Watt was appointed Director of the BPU in 1967, and became the first Scientific Director of the new purpose-built facility in 1971 when building operations commenced.<sup>10</sup> In 1974 the PFC relocated to Liberton in Edinburgh.

### **Demand for blood products for coagulation disorder patients**

**19.12** There was considerable, and growing, uncertainty about levels of demand for haemophilia therapy in the UK as a whole. At 5 April 1971, it was recognised that the total ideal requirement of material for treating patients with coagulation defects was not known.<sup>11</sup> In 1969, the material used for treatment of 1032 haemophilia and Christmas disease patients at the 30 centres from whom records were received by the UK Haemophilia Centre Directors' Organisation (UKHCDO) then located in Oxford, was derived from 84,906 donor units, an average of just over 82 donor units per patient. The products used were:<sup>12</sup>

Amounts used		
Material	No of Donor Units	% total
Plasma	11,435	13.46
Cryoprecipitate	59,715	70.34
Concentrates	13,756	16.20
TOTAL	84,906	100.00

<sup>8</sup> Minutes of meeting [SNB.010.2066]

<sup>11</sup> *Report on progress of an MRC Cryoprecipitate Working Party Survey*, provided to a meeting of Haemophilia Centre Directors in Oxford on 5 April 1971 [DHF.001.1811] at 1820

<sup>12</sup> *Ibid* [DHF.001.1811] at 1824

**19.13** This was said certainly to provide an underestimate of requirements. By way of example, it was observed that there was a waiting list of haemophilia patients requiring non-urgent surgery at Oxford and that it would require material from 10,000 donors to carry out the operations.<sup>13</sup> And the introduction of home treatment was expected to increase the amount of material used. It was noted that a record of total use year by year would give an estimate which would level off to ideal requirements. The annual figure could form a basis for an estimate of the amount of concentrate that might be required.

**19.14** Dr Rosemary Biggs and colleagues reported numbers for 1969–71 in a report prepared for the MRC.<sup>14</sup> Over that period 1608 different patients attended haemophilia centres. On their calculations, taking account of other sources of information, the minimum total number treated was estimated at 2434. That was rounded up to 3000, as an estimate of the number of haemophilia patients in the UK, a rate of about five to six per 100,000 of the population, which was reasonably in line with other estimates. The report estimated the demand for Factor VIII concentrate at 35,779,800 to 50,000,000 international units for on-demand therapy.<sup>15</sup> Making allowance for major surgery and dental extractions, the total material required was likely to lie between 38,327,800 and 53,000,000 units of Factor VIII, requiring 547,540 to 750,000 blood donations per year. Home treatment would be in substitution for hospital treatment, and would not generate additional demand. Prophylactic treatment was thought to be impractical at that stage.

**19.15** Mr Watt, the Scientific Director of the PFC, proceeded on a different basis when calculating need at June 1973.<sup>16</sup> He calculated the need for Plasma Protein Solution (PPS – a product of the final stage of Cohn fractionation, Fraction V), and concluded that the volume of plasma required for the preparation of antihaemophilic globulin (AHG), at Cohn stage I, would be readily achieved if his PPS target was met. He assumed that the population of the UK was 60 million, and the population of Scotland 5 million. The number of haemophilia patients in the UK was assumed to be 3000 (5/100,000). He calculated that the Scottish need for fresh frozen plasma for processing to meet the needs of the haemophilia population was 15,000 donations per million of population (45,000 donations) to provide 4.8 million plasma units per million population, or 20,000 plasma units per haemophilia patient per year. Extrapolated first to England and then to the UK as a whole (on the basis that there should be little difference in community need and that therefore the Scottish figures of need could be applied), he concluded that English need for AHG would be 48,000,000 plasma units, and total UK need would be 53,000,000 plasma units.

**19.16** In Mr Watt's view, the English facilities could not achieve the necessary level of production and the PFC would require to process material for England. He argued that development of the site at Liberton would be the most economic and rapid means of achieving adequate fractionation capacity for the UK. He said:

B.P.L. and P.F.C. are each specified for 70,000 – 80,000 litres of plasma per year. It is my opinion that B.P.L. production could be increased to about 150,000 litres but further increase would appear impossible on the present site and could hardly be justified. The difference of more than 250,000 litres includes 35,000 to 40,000 which the P.F.C. must process for Scotland.

<sup>13</sup> Ibid [DHF.001.1811] at 1820

<sup>14</sup> Report by Dr Biggs *et al*, [SNB.001.4871]

<sup>15</sup> The international unit (IU) was a measure of Factor VIII activity. The assumed level of activity in a given quantity of blood provided the conversion factor adopted, and varied from time to time.

<sup>16</sup> Watt, *Plasma fractionation in the United Kingdom – a personal appraisal*, (Draft) 12 June 1973 [SNB.010.1991]

**19.17** He noted that there was a risk of a dual standard of clinical availability as between Scotland and England, an intolerable situation which, he thought, could not be maintained.

**19.18** At this stage, in the early 1970s, as Dr Biggs' report indicates, the Haemophilia Centre Directors recognised that the pattern of demand was changing, and that data for actual demand would be required to form a view of ideal requirements. In the event, data returned for 1970 and 1971 saw the volumes used increase, in terms of blood donations used, to 105,531, and then to 132,743 donations. In 1971, 1100 patients were treated at the 35 centres which reported, at a rate of 120.7 donations per patient per year, not including donations used in elective surgery or dental procedures. The comparative figure for 1969 was 84.9 donations per patient per year.<sup>17</sup> As indicated later, by early 1973 it was recognised generally that considerably more concentrate was required than the output of the UK facilities if the needs of haemophilia clinicians were to be met.

**19.19** These changes in perception of the likely levels of demand were taking place as construction of production facilities was at an advanced stage of planning or had already begun in England and Scotland. In November 1969, there was a meeting at the RIE between the SHHD and the Blood Transfusion Services of England and Scotland.<sup>18</sup> It was reported that it would be about one year before contractors could move onto the site of the new Scottish fractionation centre, and it was estimated that commissioning would be completed in the latter half of 1974. Tenders for the work had been received by July 1971. Building of the new extension at the BPL had begun in November 1969 and was expected to be completed in September 1971.<sup>19</sup> Having gone to tender, and on to concluded contract, flexibility to respond to changing demands was necessarily limited, in the short term at least.

**19.20** In this period of change, those planning developments appear to have depended on the Haemophilia Centre Directors for information about demand for Factor VIII and IX (cryoprecipitate or concentrates). The 1969 data referred to above were not available until 1973, still less the 1970 and 1971 figures. None of these data provided a reliable basis for forecasting growth, and they could not have provided a rational basis for projecting UK demand based on donor units. Furthermore, planning for the size and capacity of the new UK fractionation facilities coming on stream in the early 1970s had been carried out at a time when there had been no clear idea whatever of possible future demand for Factor VIII and Factor IX products.

**19.21** Later analysis of data would have further undermined the reliability of the 1969 figures as a basis for projecting demand. Between 1969 and 1973, new demands were placed on suppliers by clarification of the numbers of patients needing treatment, and developments in the forms of treatment, such as home treatment of coagulation disorder patients and, to a lesser extent, prophylactic treatment, increasing the difficulties inherent in projecting demand. Further research was required. But the facilities already planned proceeded and were duly commissioned against a background of insufficient production to meet UK requirements as a whole.

## Changing demand and the development process

**19.22** In July 1971, there was a further meeting at the RIE between the SHHD and the Blood Transfusion Services of England and Scotland.<sup>20</sup> It was agreed that discussions on central processing of Factor VIII and Factor IX concentrates were imperative because of major effects on production planning. Work began at Edinburgh with a planned commissioning date for the new PFC in January 1974,<sup>21</sup> which coincided, in the event, with the start of the reference period for this Inquiry.

**19.23** However, the wider context for these discussions changed early in 1973. The first UK licences for the US commercially produced Factor VIII concentrates Hemofil and Kryobulin were granted on 19 February and 22 March 1973 respectively.<sup>22</sup> On 6 March 1973, the Chief Medical Officer (CMO) for England and Wales wrote to all Senior Administrative Medical Officers.<sup>23</sup> He said:

The production of the human concentrate in the UK is at present insufficient to meet the stated needs of clinicians who care for patients requiring surgical, including dental, treatment or who have episodes of severe bleeding. The indications are that considerably more of this preparation would be used if it were available.

**19.24** The DHSS assembled a group of experts to advise generally on the likely trends in treatment of haemophilia and, more specifically, to make proposals on which realistic planning for the future could be based. The group met on 20 March 1973.<sup>24</sup> It was recognised that the scale of the problem had been underestimated and that UK production was less than required to meet anticipated demand.

**19.25** An updated version of Dr Biggs' report was available, still based on data for the period 1969–71.<sup>25</sup> On broadly the same assumptions as before, Dr Biggs estimated total demand for all types of therapy, excluding prophylaxis, at between 400,000 and 750,000 donor units per year. It was agreed that 400,000 donations would be required to treat UK sufferers, and more if strenuous efforts were made to clear surgical waiting lists and if home treatment or, eventually, prophylactic treatment were to become acceptable forms of therapy. Those planning for demand now had information from the haemophilia directors of their expectations for future demand. But it was recognised that a broader membership was required, including Regional Haemophilia Director, and Transfusion Director, representatives, the National Medical Director of the SNBTA and Mr Watt of 'the Edinburgh BPL'.<sup>26</sup>

**19.26** The expert group's views on the development of domestic facilities at March 1973 were:

It is essential the production and distribution of the therapeutic agents concerned should be considered as a U.K. exercise.

<sup>25</sup> *Factor VIII Concentrates and the Treatment of Haemophilia*, Report by Dr Biggs [SNB.006.7775]

<sup>26</sup> Minutes of Expert Group on the Treatment of Haemophilia, 20 March 1973 [SNB.006.7631] at 7634

Close co-operation between England (including Wales and N. Ireland) and Scotland will be required in order to co-ordinate and optimise blood collection and transport, the fractionation processes, distribution of the therapeutic agents, and utilisation of other blood fraction by-products.<sup>27</sup>

**19.27** Recommendations of the group included that the UK should aim to become self-sufficient as soon as possible by increasing home production of freeze-dried concentrate. It would have been anticipated at the time that production would take place at the new PFC facility in Liberton in Scotland, still to be commissioned, and at the BPL and at the PFL in England.

**19.28** On 27 March 1973, there was a meeting at the BPL between the SHHD and the Blood Transfusion Services of England and Scotland.<sup>28</sup> The BPL facility was by that stage taking in plasma at its planned capacity of 1500 litres per week.<sup>29</sup> Good progress was reported in the construction of the Edinburgh fractionation centre, with commissioning expected to start in April 1974. The work was in fact completed at the end of 1974.<sup>30</sup> The total cost was expected to be just over £1 million. But there was still a degree of uncertainty about the scope of the plant's operations. There was concern that planning for annual requirements was inadequate. The processing of time-expired plasma had been provided for. But the Scottish facility did not have the capacity to process English fresh plasma. That was still to be considered for the UK as a whole. At this stage, when the use of coagulation factors was increasingly seen as of central importance in the treatment of haemophilia patients, the final planning of processing of raw material and production was still incomplete.

**19.29** The policy context for development took a change of direction when, on 20 June 1973, the first meeting of a Joint Steering Committee on Blood Products Production was held, bringing together DHSS and SHHD officials, representatives of the production facilities and Regional Transfusion Directors.<sup>31</sup> The policy implications of the entry of commercial producers into the market were acknowledged:

The first meeting of the Steering Committee had been precipitated by the fact that product licences had been granted to two firms to import antihaemophilic globulin concentrate which might entail large sums being spent by NHS authorities on these products.<sup>32</sup>

**19.30** Full-scale production had been achieved at the BPL. Mr Watt provided information on the programme and timetable for commissioning the PFC. Production targets were explained, as were limitations on plasma supplies. The PFC's capacity could be expanded, but it was urgent for the facility to know what volume of plasma it would be asked to process for England. The views that emerged included: (a) adopting the lower of Dr Biggs' estimates of demand for plasma at 400,000 donations as a first target, with her upper estimate of 700,000 donations as the ultimate target; (b) an initial aim of processing 250,000 donations by 1975; (c) preparation of 90% of total output as intermediate potency concentrate, and 10% as high potency product; and (d) self-sufficiency for the UK by 1975. DHSS indicated that a system of call-off contracts for imported material was

under consideration. Other developments were set out as possibilities.<sup>33</sup> It was noted that Scotland had apparently nearly reached and might exceed its proportion of the target for donations for the treatment of haemophilia suggested by Dr Biggs.

**19.31** In an undated report prepared for the MRC's Transfusion Research Committee, and made available for a meeting of Haemophilia Centre Directors on 31 January 1974, Dr Biggs and her colleagues set out a comprehensive review of the position based on studies of the period 1969–72.<sup>34</sup> The report again included an attempt to estimate the total amount of therapeutic materials containing Factor VIII activity that was likely to be needed in the UK together with the amount of fresh whole blood required for processing to meet that target.<sup>35</sup>

**19.32** Making allowance for haemophilia patients attending general hospitals, and extrapolating from accurate data for the Oxford Haemophilia Centre, the report estimated that, while they had information on 1100 patients attending 35 haemophilia centres in 1971, the number of haemophilia patients treated in 1971 in the UK as a whole was between 2434 and 3000.<sup>36</sup> Using data for donations used for cryoprecipitate and freeze-dried concentrate production and taking account of yield, the report concluded that for all types of bleeding (spontaneous, during surgery and for dentistry) the total demand required was between 547,540 and 750,000 blood donations per year. Home treatment would require 250,000 donations, as an alternative, but not cumulative, form of therapy. Prophylaxis would add further demand, but that approach to therapy was not recommended. At the time, 1.7 million blood donations were collected annually by the Blood Transfusion Services for all uses, including transfusion in surgery and medical procedures.

**19.33** Subsequently, Dr Biggs published information relating to the period 1969–74,<sup>37</sup> and the Haemophilia Centre Directors supplemented that for 1975.<sup>38</sup> In her publication covering 1969–74, Dr Biggs summarised the effect of earlier data:

[I]t was concluded that: 'An assessment of the total amount of factor VIII likely to be required for all types of treatment puts the total in excess of 500,000 blood donations annually or about 40 million factor VIII units'.<sup>39</sup>

**19.34** It was still not known how many blood coagulation disorder patients were treated at hospitals not designated as haemophilia centres, but it was thought that the previous estimate of total demand was unlikely to be excessive. The balance had shifted towards concentrate use, however, and it was now thought that 60% of Factor VIII should be freeze-dried<sup>40</sup> in order that home therapy could be instituted on a reasonable scale.<sup>41</sup>

<sup>33</sup> Ibid [SNB.006.7767] at 7769–7771

**19.35** The estimate was at the lower level in the MRC report. This series of reports by Dr Biggs and her colleagues reflects a more or less consistent application of a methodology developed by her team at Oxford. Individually, and in total, the reports show a movement towards a data-based assessment of demand that was not available previously to those planning the BPL and the PFC. As noted above, Mr Watt had a different view of total demand: he thought that demand could be higher. But the differences were not great in the overall scheme of things at this time.

**19.36** The comparison with the 1969 assessment is stark: by 1974, estimated use was over four times the use reported for 1969. Later papers showed dramatic growth in demand, reported generally in terms of international units, though falling short of the estimate of 40 million units within the period in question. By 1974, total demand had increased to 20,548,060 units of Factor VIII and 4,866,380 units of Factor IX (roughly equivalent to 300,000 blood donor units), amounts still far in excess of the 1969 estimate.<sup>42</sup> For 1975, the amounts increased to 24,886,218 units of Factor VIII, and 4,914,643 units of Factor IX.<sup>43</sup>

**19.37** It seems likely that a number of considerations affected the 1969 data. One matter affecting its reliability was exposed in the report prepared by Dr Biggs for the MRC in 1974, and repeated with reference to a later period in a report on behalf of the Haemophilia Reference Centre Directors published by Dr Biggs and Dr Rosemary Spooner in May 1978.<sup>44</sup> The 1978 report noted that data from 1974 implied that patients with haemophilia were attending hospitals which were not recognised as haemophilia centres under the designation scheme that had been in place since the mid-1950s. A survey was carried out. It disclosed a significant number of cases of treatment in hospitals that were not designated. The report observed that all severely affected patients would require frequent anti-haemophilic treatment each year, most of the moderately affected patients would require treatment two or three times a year, and that many of the mildly affected patients would require treatment at least once a year. The directors were concerned that large numbers of patients with Haemophilia A or B were not seen at a haemophilia centre to establish a diagnosis. In their opinion any patient who had a coagulation defect should be seen at a haemophilia centre for that purpose. To ensure a suitable supply of therapeutic material and the highest standard of treatment available, the care of these patients should also be coordinated by a haemophilia centre.

**19.38** The authors' primary concern was for the welfare of the patients. But the information required to prepare a valid projection of overall need for therapeutic material was deficient. That deficiency continued to be as significant in 1974 as it had been when assessing demand several years earlier.

**19.39** Other workers commented on factors that were creating increasing demand at about this time. Home treatment increased demand for factor concentrates in 1975 and 1976.<sup>45</sup> Dr Peter Jones and his colleagues at Newcastle examined data from all UK haemophilia centres and provided a picture of growth, from very early cases in 1960, and from the introduction of cryoprecipitate in 1964, but more particularly in 1975 and 1976. Over those two years, the number of patients on home treatment, or in training for home

treatment, rose from 267 to 488. In addition, the directors of the centres estimated that 280 additional patients were awaiting entry to the scheme in 1975 and 241 in 1976. The products used included cryoprecipitate and factor concentrates, and the latter included a wide range of commercial products. Dr Jones and colleagues reported a significant rise in demand due to the number of patients involved; the variables in assessment of effective dosage; the use of prophylaxis; and the adequacy of supply. They commented that the demand in the UK as a whole could not have been met without recourse to commercial Factor VIII concentrates. About 55% of the blood product used for home treatment was imported, and in England and Wales necessarily so, because of the continued shortfall in production of NHS concentrate from voluntary donations.

**19.40** Dr Jones continued to promote the benefits of home therapy well after this period. In 1980, he edited a handbook for those involved in treatment, and for patients, that was published by Pitman: *Haemophilia Home Therapy*.<sup>46</sup> Home treatment was to continue to be a major element in total demand.

### The position in 1974 – the beginning of the reference period

**19.41** By 1974, the PFC was manufacturing a wide range of products: fibrinogen, human albumin, anti-vaccinia immunoglobulin, anti-D immunoglobulin, prothrombin complex (Factors II, VII, IX and X) concentrate, anti-tetanus and anti-rubella immunoglobulin. In 1974, production began of a new-generation intermediate-purity Factor VIII concentrate ('NY' Factor VIII). Manufacture of this range of products was impaired in 1974 and 1975 by the move to Liberton. Dr Peter Foster, who specialised in biochemical engineering and who was to play a major part in scientific developments at the PFC, joined the service in 1973. The new plant was in routine operation from 1976.

**19.42** Production targets and the scope of operations continued to be open for discussion. There was no concluded policy as to the extent of the facility's use, especially in relation to the processing of material from England and Wales. However, the lack of a formal policy at that time became more or less irrelevant. The Annual Report of the SNBTS for the year ended 31 March 1976 noted that the plant had been designed to accommodate material from England and that staff had been recruited and trained on the basis of shift-working.<sup>47</sup> But opposition from the trade unions, allied with demands relating to terms and conditions of employment which the employers found unacceptable, had made shift-working impracticable. In the result, the PFC could cope with Scottish needs on a day-staff only basis, but the absence of the other shifts decreased cost-effectiveness and precluded acceptance of plasma from furth of Scotland. At the beginning of the reference period, therefore, there was considerable doubt about the levels of demand that ought properly to be anticipated, and this necessarily affected the efficiency of planning of the production facilities required. Since the PFC had been conceived as one element in the total UK production capacity, its planning was directly affected.

**19.43** Some English plasma was dispatched to Edinburgh. On 11 April 1977, Mr Watt reported to the SNBTS that he held 10,000 litres of plasma from England, but did not have any arrangement in place for processing it.<sup>48</sup> By July, the quantity had increased to 20,000 litres. The minutes of a meeting of the SNBTS Directors on 12 July 1977 noted that a

<sup>46</sup> Jones, P., *Haemophilia Home Therapy*, 1980, Pitman, London.

<sup>48</sup> Letter from Mr Watt to Miss Corrie, 11 April 1977 [SNB.002.1777]

system for handling English material that was acceptable both to BTS England and Wales and to the SNBTS would have to be evolved.<sup>49</sup> That had not been achieved by mid-1977.

**19.44** The issues remained unresolved by 17 January 1978, when again Mr Watt reported to the SNBTS Directors that the English plasma was still in store.<sup>50</sup> It was thought that it would require a plan drafted by the Joint Committee on Blood Products Production and agreed by Transfusion Directors north and south of the border to resolve the impasse. In the meantime, it was generally agreed that Scotland should secure its own supply of fractions before undertaking work for NBTs. Pending an agreement on shift-working Mr Watt felt he could process a limited amount of the plasma from the BPL on the basis of an extended working day, to ascertain the yield and establish costs. Directors agreed that he should do so, possibly devoting two weeks to fractionating English plasma only.

**19.45** The Joint Committee on Blood Products Production involving the Scottish service and that of England and Wales did not resolve these issues. In the event, it was decided that the PFC could deal with Scottish needs only, but could not take plasma from furth of Scotland. For the time being at least, the PFC would process Scottish plasma, and service the Scottish market alone. Arrangements were made for supplying Northern Ireland later.

**19.46** In retrospect, the final stages in the planning, commissioning, and initial use of the new PFC facility at Edinburgh therefore took place against the background of an underestimate of the demand for coagulation products in the UK generally, at a time when demand was increasing for a number of reasons, and without firm arrangements for the optimum use of the facilities planned for Scotland. The failure to take account of emerging demands related to new regimes such as home therapy and prophylaxis is understandable. In the initial planning stages of the PFC these treatment regimes would not have been developed as aspects of haemophilia practice. As discussed in Chapter 21, *Haemophilia Therapy – Use of Blood Products*, there was an element of reaction to the availability and importation of US concentrates that changed the pattern of demand. This came after the plants at the BPL and the PFC were built or in construction. And much of the latent demand for treatment could only be known when therapeutic materials became available for use.

**19.47** The result, however, was that for a considerable time Scottish premises were adequate and, with the processing plant required, coagulation products could be provided to meet the demands of clinicians in Scotland, while in England and Wales there were persistent deficiencies that had to be made good by commercial purchases.

### Self-sufficiency

**19.48** There had already been a political commitment to self-sufficiency, however. In December 1974, Dr David Owen MP, the UK Minister of State for Health, had announced exceptional government funding of £500,000 with the primary aim of making the NHS self-sufficient in blood products within two to three years, following recommendations by the World Health Organization (WHO).<sup>51</sup> The WHO reinforced its position in 1975.<sup>52</sup> The funding was to be used to provide the BPL in London with additional equipment

to process the increased quantities of plasma necessary to meet the rapidly increasing demands for clotting factors for treating haemophiliacs.

**19.49** So far as Scotland was concerned, it could not have been concluded at the beginning of the reference period that the country was or would be self-sufficient in Factor VIII blood products until the PFC was fully operational. The Annual Report of the SNBTS for the year ended 31 March 1976 reflects the developing position.<sup>53</sup> The commissioning of the PFC was almost complete, and full production to meet Scottish needs was said to be in sight, provided that appropriate supplies of plasma were forthcoming from the regions. As events were to unfold, it would be several years before the supply of plasma from the Scottish regions took up the PFC's production capacity.

**19.50** Progress towards self-sufficiency depended on policy decisions, and on raw material supplies to meet processing targets that were yet to be set and implemented. However, at this time there was a lack of confidence about the future. On 8 May 1975, the SNBTS and Haemophilia Directors met with SHHD officials.<sup>54</sup> Officials were conscious that, in advice given on replies to parliamentary questions, ministers were constantly being informed that, when the PFC was fully commissioned, long-term supplies of Factor VIII concentrate would be assured. It was observed that it was still not clear what the timetable was for the replacement of cryoprecipitate by concentrate: so long as there was significant use of cryoprecipitate, the full demand for concentrates would not be known, and the necessary full supply of plasma might not necessarily be available. The minutes of the meeting disclose little hard information, and expose wide-ranging doubts. No firm conclusions were reached on future demands. At the following meeting on 14 November 1975, there was little progress on demand. A study group was set up, convened by Major-General H.C. Jeffrey (National Medical Director of the SNBTS), and a pro-forma prepared for the collection of data.<sup>55</sup>

**19.51** More generally, there was explicit acknowledgement that Scotland was in part dependent on imported products prior to the full commissioning of the PFC. In England and Wales, central contracts for the purchase of commercial Factor VIII were held by the Department of Health from 1972–79.<sup>56</sup> On 11 June 1975, at a meeting of the SNBTS Directors, the procurement of commercial blood products was raised. It was noted that:

In response to a query from Dr Cash, General Jeffrey explained that SHHD had under urgent consideration the issue of whether commercially produced blood fractions which might be required should be purchased by the SNBTS or by Health Boards.<sup>57</sup>

**19.52** On 30 September 1975, at a subsequent meeting of the SNBTS Directors:

It was explained that, because of the comparatively minor nature of the problem, it should be left to Directors to purchase and distribute human blood products should this prove necessary. This was an ad hoc arrangement pending full commissioning of the PFC.<sup>58</sup>

<sup>58</sup> Minutes of meeting [SGH.001.6135] at 6137

**19.53** Commercial purchases were not centralised in Scotland, and it was left to local health boards and their officers to purchase and distribute commercially produced blood fractions as required. This became a factor in relation to the assessment of total demand, and in particular, to the assessment of the production requirements at the PFC. In one of two 'World in Action' television programmes broadcast in or around the end of 1975, Mr John Watt stated that, with sufficient plasma supplies, the PFC, Edinburgh, could supply Factor VIII concentrate for about half of the needs of those with haemophilia in Britain.<sup>59</sup> However, its capacity was not fully utilised: the intention to process plasma from England was never realised. Mr Watt's interview caused concern. In a letter to the *British Medical Journal* dated 24 January 1976, Professor John Cash commented that the programme had created a misleading impression. He wrote:

Perhaps the most important misleading feature of the second television programme was the impression given that the recent and specific injection of £500,000 into the blood transfusion services will have worked its way through by mid-1977, and by that time the necessity to purchase further supplies of factor VIII concentrates will be eliminated. Our own experience indicates that this will not occur, not least because the present NHS production target for factor VIII concentrates is too low. What seems more certain, however, is that by mid-1977 we shall begin to understand that the problems are multifactorial, a good deal more complex than hitherto appreciated, and only partly related to the haemophiliac.<sup>60</sup>

**19.54** The failure to provide for total demand and the implied acceptance that the UK was heavily dependent on imported products were factors clearly acknowledged within the service throughout the UK. In the event, however, Scottish use of imported Factor VIII would prove to be relatively modest until about 1980.

### Demand levels re-assessed

**19.55** Professor Cash and Dr Mary Spencely discussed the issue of demand for Factor VIII products in Scotland in September 1976.<sup>61</sup> They expressed concern about forecasts based on Dr Biggs' research in 1974,<sup>62</sup> because of the wide range of values brought out. In their study in the south east of Scotland region based on treatment between 1961 and 1975, they had found a substantial increase in the donations required for Factor VIII production over the period. They had observed abrupt increases in demand in 1964, with the introduction of major reconstructive surgery. Subsequently, there were increases due to the gradual introduction of on-demand treatment; available to all patients. Demand increased from about 1300 donations in the period 1961–63, and reached a new plateau of about 2750 donations by 1970.

**19.56** Cash and Spencely suggested that a saturation level might have been reached. Like other commentators, they had not anticipated further changes in the pattern of demand, nor, ultimately, in the number of haemophilia patients with unmet needs. Furthermore, some of their data were specific to Edinburgh and south east of Scotland. Possible

<sup>62</sup> Biggs *et al*, 'Factor VIII concentrates made in the United Kingdom and the treatment of Haemophilia based on studies made during 1969–72', *British Journal of Haematology*, 1974; 27: 391 [PEN.016.0341]. (This is the published version of the typescript paper made available to the UK Haemophilia Directors meeting on 31 January 1974 – See paragraph 19.31 above.)

concerns about the approach adopted were set out in paragraphs 5.109 and 5.110 of the Preliminary Report. The suggestion that a level of saturation might have been reached remains an odd feature of the analysis. The success of factor therapy had to be reflected in an increase in life expectancy of haemophilia patients, and the concomitant extension of the term of treatment of the average haemophilia patient. One would have expected a rising trajectory even if all other factors had remained constant: treatment years per patient had to increase. As will appear, there was also the start of home treatment, and availability of imported products had already by 1975 found a response in demand for treatment of patients who had not been catered for previously.

**19.57** A further difficulty was that the paper depended on data peculiar to the region. No commercial products were used in south east Scotland over the period of the study. But there was extensive use of commercial products in Glasgow.<sup>63</sup> In the Glasgow and south west of Scotland region there was also extensive use of cryoprecipitate as the therapeutic product of choice. Apart from distinguishing the two regions' use of therapeutic materials, these two factors underline a basic issue over the definition of demand for NHS products generally. So long as haemophilia clinicians were free, in the exercise of their very considerable clinical autonomy, to elect for commercial products or for products other than concentrates in treating their patients, actual demand for NHS concentrates could never be relied on as a measure of total demand for therapeutic products generally. The position in Edinburgh and south-east Scotland over the period of study reflected the firm and apparently unwavering commitment of the then Haemophilia Director, Dr Howard Davies, to NHS material, much of it cryoprecipitate. That was not the position in Glasgow and south west Scotland, the largest region of the country. Imported material was making a significant contribution (over 90%) to the demand for Factor VIII concentrate in the period 1971–74. In both regions at that period there was significant use of cryoprecipitate, again reflecting the choices of the Haemophilia Directors at the time.

**19.58** The use of cryoprecipitate for the treatment of adults in the west of Scotland was reflected in the well-established pattern of production of cryoprecipitate in that region during the periods when successively Dr John Wallace and Dr Ruthven Mitchell were the SNBTS consultants in charge. Dr Davies in Edinburgh was also an advocate of cryoprecipitate use. Professor Cash and Dr Spencely based their calculations on the assumption that 70% of the therapeutic material used would be cryoprecipitate, reflecting product choice in the east of Scotland at the time. A material shift in haemophilia practice towards use of concentrate would necessarily depend on production capacity and the supply of raw material in the form of frozen plasma.

**19.59** The views set out by Cash and Spencely in this paper were clearly not accepted universally. In the paper, they commented at some length on the choice of therapeutic materials, and the efficiency of production of cryoprecipitate as against concentrate. But it is in the authors' estimation of demand that the paper is interesting for present purposes. They concluded that the Blood Transfusion Services should consider a production target of an average of 15,000 units of Factor VIII per patient per year with a total UK annual requirement of around 50 million units. Converting that into donations per million of population per year threw up a range of values from 15,000 to 20,000, with the qualification that the higher figure would rise further if the volume of fresh plasma obtained from each donation was reduced.

---

<sup>63</sup> See Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*

**19.60** At the date of the Cash and Spencely paper in September 1976, the authors believed that, following the commissioning of the PFC, the south east of Scotland was already self-sufficient in therapeutic Factor VIII products. But there remained considerable issues about the rest of Scotland. It was recognised that supplies of antihæmophilic factor (AHF) (concentrate) were limited: 'What supplies of AHF there are, should be reserved for outpatient use, while cryoprecipitate is used for inpatients'. The conclusion of the paper was:

In the meantime the blood transfusion services ought to look towards improving the quality of cryoprecipitate production and procedures for the procuring of bulk fresh plasma. The plasma fractionators should look towards technical developments that will lead to improved yields, the general hospital medical staff towards a dramatic increase in the use of red cell concentrates and packed red cells in preference to whole blood, and the staff of regional hæmophilia centres to the more economical and critical use of factor VIII concentrates. There is no evidence to suggest that the voluntary blood donor will not respond; indeed those in the regional blood transfusion centres know that quite the reverse is true.

**19.61** It is implicit in the proposals for restricted use that there would be deficiencies in supply if there was a significant change towards concentrate use. The authors advocated the use of packed red cells as a way of releasing more plasma for production. Apart from increases in the volume of plasma for processing, any deficiencies in domestic supplies of Factor VIII concentrate could only have been made up by the purchase of commercial products, which was already happening in the west of Scotland. Of possibly greater significance, so far as developing a strategy for self-sufficiency is concerned, is the clear message that there was no settled practice governing the choice of product for well-recognised categories of application. In particular, the factors identified as relevant to the choice of product were related to the economics of manufacture, and yield, predisposing the authors to recommend cryoprecipitate in preference to Factor VIII concentrates.

**19.62** An attempt to assess the resources for the adequate treatment of Scottish hæmophilia patients was set out in a paper prepared for a meeting of the SNBTS and Haemophilia Directors on 4 October 1976.<sup>64</sup> There were 436 registered hæmophilia patients. Their distribution across Scotland was: Glasgow 285, Edinburgh 95, Aberdeen 25, Dundee 17 and Inverness 14. Twenty to 22 of these required treatment three or four times a year. Eighty seven to 92 required more frequent therapy. The rest hardly ever required treatment or required it not more than twice a year. The data were not entirely reliable because of the practice of some patients of attending general hospitals. Factor VIII usage in the first six months of 1976 presented the following picture of the current position:<sup>65</sup>

	Aberdeen	Dundee	Edinburgh	Glasgow	Inverness
Cryoprecipitate as donations	467	121	5965	8829	154
PFC Factor VIII: vials	288	111	(307,700 units) 1231	1381	358
Commercial Factor VIII	0	0	0	(90,740 units)	0

<sup>64</sup> *Resources required for adequate treatment of Scottish Haemophiliacs* [SNB.001.4943]

<sup>65</sup> *Ibid* [SNB.001.4943] at 4944]

**19.63** There are obvious problems with the data. The inconsistent use of units of measurement is very confusing. An apparent problem is the absence of recorded use of commercial product outside Glasgow coupled with low use of PFC Factor VIII. Availability of the PFC concentrate at this period was affected by the transfer of production from the RIE to the new PFC. The data are not sufficiently specific to factor this into the assessment of the validity of the exercise. The impression given, as far as haemophilia treatment is concerned, is that at this time, as was clearly the case in Glasgow, most plasma was being retained locally for cryoprecipitate production, but the extent to which the disruption of the PFC supplies affected practice is unknown, and there remains a question whether the reports of commercial usage can be treated as wholly reliable.<sup>66</sup>

**19.64** Nevertheless, there is a marked difference between the Glasgow data for the first six months of 1976, and for the full year 1975 (as the PFC began to come on stream). For 1975, total cryoprecipitate of 26,616 donations and PFC Factor VIII of 1023 vials were recorded as used.<sup>67</sup> Superficially, the rate of use of PFC Factor VIII had more than doubled. The paper listed a number of topics for discussion which highlight concerns at the time over the assessment of total demand. These included the numbers of patients with haemophilia, moderate and severe, in the community; the amount of Factor VIII (cryoprecipitate and concentrate) required for each patient; the best use of resources; patients' lifestyles; and the follow-up and evaluation required. It was suggested that a national register might be justified. Two points warrant specific reference: the effect of home therapy on total consumption and, related to that, the approach to decision-making on suitability for home therapy; and the introduction of new surgical techniques likely to make heavy demands on resources over relatively short periods.

**19.65** The assessment of demand had begun to take into account factors that were to become significant within a short period. The context for the discussion had to take account of government policy to use blood from voluntary donations, in keeping with the WHO recommendations.<sup>68</sup>

**19.66** The minutes of the meeting on 4 October 1976 note that estimating requirements for Factor VIII had been causing concern at UK level.<sup>69</sup> The cost of maintaining a UK-wide register was said to be a 'practical obstacle' to implementation of that proposal. Two points were noted as being of particular concern: the increasing needs for clotting factor products as a child grew older, and the increasing prospects of longevity. The wider context was reflected in two paragraphs, the first of which (paragraph 7) said:

The primary need was seen as the provision of information to help on balancing use and requirements. Use would obviously increase if patients took up and were encouraged to take part in eg skiing or other outdoor pursuits. It was becoming increasingly apparent that haemophiliacs should be advised to live within the limits of their disability and in the more severe cases this could lead to them living a more sedentary life. While it was acknowledged that this is a difficult area, impinging as it did on the question of clinical freedom, it was thought to be a realistic approach.<sup>70</sup>

<sup>66</sup> The disruption due to the relocation of the PFC is discussed in Chapter 21, *Haemophilia Therapy – Use of Blood Products*, at paragraph 21.47

<sup>67</sup> 'Resources required for adequate treatment of Scottish Haemophiliacs' [SNB.001.4943] at 4944

<sup>69</sup> Minutes of meeting [SGH.001.1320]

<sup>70</sup> Ibid [SGH.001.1320] at 1321

**19.67** The following paragraph (paragraph 8) proposed a UK-wide meeting with the Haemophilia Society with a view to discussing the use of the scarce resources available and other topics on a UK basis that might lead to the production of a register among other things. The importance of an agreed policy for Scotland with the support of clinicians in England and Wales was stressed.

**19.68** An exploratory meeting of Blood Transfusion Directors and Haemophilia Reference Centre Directors was held in Sheffield on 22 October 1976.<sup>71</sup> Dr Biggs and colleagues presented the data on need, estimated at 40 million units of freeze-dried Factor VIII. International data suggested a need for England, Wales and Northern Ireland of 36,481,890 units, and for Scotland 3,741,917 units, giving 40,223,807 units in total. These figures presented a picture of spurious arithmetical accuracy, but they agreed fairly well with estimates based on UK data. They anticipated a shift from the use of cryoprecipitate to the use of concentrates, noting that five commercial companies were licensed to supply very satisfactory products which offered convenience in use.

**19.69** In discussion, Dr Biggs is reported to have commented that 40 million units was too low an estimate for the future because use was increasing. Professor Cash agreed. He was alarmed by the games and sporting risks now covered and the implications for demand: he thought it was morally wrong to commit such large amounts of material.<sup>72</sup> Dr Wallace pressed for a common policy, but he too reflected the view that haemophilia patients should live within the limits of their disabilities.<sup>73</sup> In contrast to the views of these suppliers of clotting factor products, a representative of the 'consumers', the Haemophilia Centre Director Dr Jones, was of a different view, encouraging normal sporting activities such as football: if patients sat around they would need more therapy.<sup>74</sup> He proposed a target of 42.4 million units. Following extensive discussion, the final proposal, from Professor Colin Prentice, was that the current target should be 40 million units, rising to 50 million units over the following three years.<sup>75</sup> There were doubts about the usefulness of the exercise.<sup>76</sup> The fractionators were not in agreement about the criteria to apply and about the practical implications of working to the targets proposed. At least some haemophilia directors were apparently not according priority to the goal of UK self-sufficiency in blood products, particularly Factor VIII concentrates, and appear to have been content to continue to use increasing amounts of imported products rather than their domestic counterparts.

**19.70** At a meeting of the SNBTS Directors on 26 October 1976, in discussing the supply of Factor VIII concentrates, it was noted that, in Scotland as in England and Wales, there was still a long way to go towards setting ultimate targets for the production and use of Factor VIII products, though Scotland's problem was smaller than in England and Wales.<sup>77</sup> It was agreed that a firm attempt should be made at the meeting of the Haemophilia Directors planned for 24 January 1977 to set interim Scottish targets.

<sup>71</sup> The full list of participants sets out the major players in the field (other than DHSS, SHHD and Northern Ireland government officials, who had not been invited) at this period. Minutes of meeting [SNB.001.4953]

<sup>77</sup> Minutes of Meeting [SGH.001.6042]

**19.71** The practitioners, in England and Wales as well as Scotland, had not resolved targets. In their paper, Professor Cash and Dr Spencely had not resolved the issue of methodology to the satisfaction of UK colleagues. Estimates of demand remained uncertain. The paper's projection of total UK demand at 50 million units exceeded Dr Biggs' estimate of 40 million, but reflected the longer-term projection for the UK as a whole. But each projection exceeded by a considerable margin the production targets on which the two major facilities in England and Scotland were planned, and constructed or developed at this time. There was little obvious collaboration between the two groups – the blood transfusionists and fractionators interested in production on the one hand, and the haemophilia clinicians preoccupied with consumption on the other. Neither group was successful in estimating demand and regulating both production and consumption in the period between 1972 and 1981 with much accuracy. A casualty of this overall lack of collaboration was the idea, or at least the practicality, of UK self-sufficiency during this period. That would become a matter of regret.

**19.72** In the event, in the UK as a whole, there was an emerging shortfall in production of growing significance. The comparative positions in Scotland and England are set out in Chapter 21, *Haemophilia Therapy – Use of Blood Products*. In retrospect it is clear that there was a material failure, at the beginning of the reference period, in the planning of production capacity to anticipate the actual emerging levels of demand; and a correlative failure to provide production facilities in the UK as a whole with the capacity to service domestic requirements. The positions in the two parts of the UK differed. In England and Wales, there was a significant shortfall in production capacity which, in absolute terms, made it impossible in the 1970s and early 1980s to produce enough material to meet domestic demand. In Scotland, the facilities were sufficient in scale, or at least flexible enough to adapt to meet growing demand, until the end of the 1970s. However, plasma supplies, yield of concentrate, out-of-date data on use of Factor VIII, and failure to appreciate the impact on total demand of changing haemophilia clinical practice all contributed to the problem there, as in the UK as a whole.

**19.73** Dr Biggs wrote a letter to *The Lancet* of 29 June 1974. It is quoted in the Preliminary Report, but captures the atmosphere at the time, and is worth repeating:

Those who treat haemophilic patients in the UK have in the past of necessity tolerated the chronic undertreatment of their patients and have put much time and effort into spreading the inadequate amounts of therapeutic material thinly so that deprivation should be least damaging. Essential but non-urgent operations have been postponed and are still being postponed. Economy has also been achieved by calculating the dose for each lesion for every patient to give the absolute minimum dose. In addition patients have not been put onto home therapy who would greatly benefit by this treatment .... There is, in fact, evidence that 90% of haemophilic patients in the UK receive less (and in some cases much less) than optimum treatment for their complaint. The consequences of this undertreatment include subjecting the patients to unnecessary, painful and destructive bleeding into joints and muscles. Ancillary effects of undertreatment include loss of educational time and inability to hold continuous employment.<sup>78</sup>

<sup>78</sup> Biggs, 'Supply of blood-clotting-factor VIII for treatment of haemophilia', *The Lancet*, 29 June 1974 [PEN.016.0440]; Preliminary Report, paragraph 5.122

**19.74** Dr Biggs proceeded to make an emotional appeal for the purchase and use of stocks of 'good quality human Factor VIII' readily available from commercial companies that were by then licensed to make supplies in this country, and dismissed, rather contemptuously, all arguments based on financial constraints. She concluded:

Whatever solutions there may be for problems of this sort in general, some immediate solution should be found for the ridiculous impasse of large available stocks of therapeutic materials locked up in stores because no-one will buy them and, on the other hand, patients in dire need of this same material.<sup>79</sup>

**19.75** At least so far as England and Wales were concerned, her comments underline the deficiencies in domestic production. As will be seen in Chapter 21, *Haemophilia Therapy – Use of Blood Products*, the purse strings were loosened and imported materials were used in large quantities as time passed. The description of the commercial concentrates in stock as 'good quality human Factor VIII' would be challenged within the following decade as the likely impact of non-A, non-B Hepatitis (NANB Hepatitis) came to be appreciated.

**19.76** It appears to be clear that the problems that preoccupied the medical profession and the technologists associated with blood product production in the mid- to late-1970s related to production capacity, cost, and adequacy of supply of therapeutic materials for appropriate treatment of the patient population. Awareness of NANB Hepatitis (later identified as Hepatitis C) became an emerging issue: AIDS had not yet been reported. As the 1980s progressed, the emphasis was to change dramatically.

### The final chapter

**19.77** The evolving history of blood product development in Scotland will be traced elsewhere in this report. At this stage, however, it is appropriate to define the end stage of the production of concentrates in Scotland, since that, incidentally, put an end finally to the pursuit of self-sufficiency and removed the scope for controversy over production targets.

**19.78** In 1998 the fractionation of plasma from UK donors was banned as a precaution against the risk that variant Creutzfeldt-Jakob disease (vCJD) might be transmitted by blood products. At UK level, precautionary concerns around vCJD risk drove the decision. Historically, sporadic vCJD was not thought to be transmissible by blood components or plasma products. When vCJD was first described in about 1996, it was recognised that it was a different kind of disease and there was concern that it might prove transmissible. The risk that, because of the pooling effect, one infected individual donor might contaminate a whole batch of products influenced the UK government to take the view that it would be preferable to move away from UK plasma. There was speculation that potentially vast numbers of people might develop the disease. Though that never came to pass, it was thought to be possible at the time.<sup>80</sup>

**19.79** It was assumed, correctly, that the risk of transmission of vCJD from blood collected in Britain was greater than the risk in source countries from which substitute supplies might be found and in which bovine spongiform encephalopathy (BSE), and hence vCJD, had not occurred. BSE was predominantly a UK-centred outbreak, with some cases in Ireland and Western Europe. Of approximately 220 to 230 cases of clinical vCJD, probably

<sup>79</sup> Biggs, 'Supply of blood-clotting-factor VIII for treatment of haemophilia', *The Lancet*, 29 June 1974 [PEN.016.0440]

<sup>80</sup> Professor Turner – Day 7, page 35

about 180 to 190 were in the UK. There had been two or three cases in the USA of vCJD but they were mainly in individuals who spent time in other countries, including the UK.<sup>81</sup>

**19.80** In the aftermath of the ban on UK plasma, it was announced in October 1998 that the SNBTS was to undergo a major modernisation programme.<sup>82</sup> Processing and testing functions were terminated at all five Blood Transfusion Centres and concentrated on two sites, Edinburgh and Gartnavel (replacing the Carluke Centre). The two national laboratories were to be developed and equipped to deal with new blood tests and processing technologies for the whole of Scotland. There was to be national coordination of the collection of blood and of blood stocks. It was also indicated that additional funds were to be allocated, among other things, for 'sourcing of non-UK plasma', presumably an indirect allusion to the risks potentially associated with vCJD in the domestic blood supply.

**19.81** There were factors other than vCJD, however, that affected the PFC's ability to continue functioning as a manufacturing facility. European regulatory authorities had pressed for additional viral inactivation following transmission of hepatitis and HIV during 1984 in Germany. These required changes in manufacturing processes and fresh clinical trials to obtain regulatory approval. New equipment was required. There was a decision to fund recombinant coagulation factor concentrates. At the same time, demand for human albumin fell following reports of adverse consequences for recipients.<sup>83</sup> These factors pointed to a further move from the PFC's established range of activities.

**19.82** While red cell and platelet production continued in Scotland; domestic blood, collected in Scotland (and throughout the UK), was no longer used for the production of plasma fractions.<sup>84</sup> As a result, the SNBTS had to import plasma or obtain it from commercial (non-UK) sources. Plasma was sourced commercially after 1999. That allowed fractionation to continue for a time.

**19.83** The next significant change in the scope of the operations of the SNBTS was prompted by the implications of the first documented clinical case of transmission of vCJD early in 2004.<sup>85</sup> The vCJD threat, together with the move away from human blood clotting factors to synthetic alternatives, contributed to the decision in June 2006 to accept the recommendations of National Health Services Scotland that it was no longer viable to operate the PFC as part of the NHS.<sup>86</sup> At the time the decision was taken production at the PFC had already been suspended due to concerns about quality assurance.<sup>87</sup> The economics of continuing production in Edinburgh influenced the decision. The PFC closed in 2008 after attempts to find a private buyer failed.

**19.84** So far as the PFC was concerned, there was a practical risk of continually recalling batches of product. The risk of recalling product carried a threat of shortages. In general terms, the PFC had become one of the smallest fractionators in the world, and was particularly small compared to large corporate commercial fractionators. But there was the added consideration that, with the end of an era of effectively free supply of plasma, the

<sup>87</sup> *Ibid*

balance of economics changed in favour of purchase of products from the international commercial community.<sup>88</sup>

**19.85** Fresh frozen plasma for clinical use is still imported for two groups of patients. One group comprises children up to the age of 16 years. For that group, plasma has hitherto been imported from the USA but in the future will be imported from Austria. That product receives methylene blue treatment, a pathogen reduction treatment which can be applied to plasma. The second group comprises patients undergoing plasma exchange, particularly for a condition called Thrombotic thrombocytopenic purpura (TTP or *Moschcowitz syndrome*). Methylene blue treated plasma is thought not to be the best treatment for them. So pharmaceutically cooled plasma, called 'octoplas', is used. It is again manufactured from European plasma. Albumin and immunoglobulins are also supplied commercially.<sup>89</sup> However, for all practical purposes, fractionation, as the definitive manufacturing process, had ceased before the decision to place the facility on the market had been taken.

**19.86** With the closure of the PFC, Scotland lost many of the skill sets associated with fractionation. The technological developments that have followed since the millennium are largely irrelevant to practice in Scotland. The BPL, the English fractionation centre, remains open, but uses imported plasma.<sup>90</sup> The English Service has a plasma collection facility in New England, USA, from which it obtains supplies for the NHS.<sup>91</sup>

## Discussion and conclusions

**19.87** The planning and construction of the extended facility at the BPL, and the new PFC, took place at a time when there was already increasing demand generated by some known factors, for example, use of clotting factor products in major reconstructive surgery and the gradual introduction of on-demand treatment, available to all patients, in the period 1961–64. In 1976, changing policy relating to patients' lifestyles, moving from maintaining a protective environment towards encouraging sport and other potentially dangerous activities, had an impact on demand. At the meeting of Blood Transfusion Directors and Haemophilia Reference Centre Directors held in Sheffield on 22 October 1976 the views of haemophilia clinicians were made explicit: normal sporting activities such as football should be encouraged. The increasing needs for clotting factor products as a child grew older, and the increasing prospects of longevity required to be taken into account. By the autumn of 1976, also, it was appreciated that home therapy would be likely to increase demand. And it was anticipated that the introduction of new surgical techniques was likely to make further heavy demands on resources over relatively short periods.

**19.88** Overall there was a changing environment in which haemophilia care would come to demand increasing quantities of therapeutic materials beyond those anticipated in the planning of production facilities. And there was the beginning of an inexorable shift towards concentrates as the product of choice in haemophilia therapy, which would become clear as the use of Factor VIII in particular grew throughout the 1970s and early 1980s.

---

<sup>88</sup> Professor Turner – Day 7, page 36

<sup>89</sup> Ibid pages 33–34

<sup>90</sup> Ibid pages 33–34

<sup>91</sup> Dr Norfolk – Day 7, page 79

**19.89** Haemophilia clinicians' treatment policies, and the encouragement of patients to live a 'normal' lifestyle, associated with clinical independence that extended to the selection of therapeutic products thought best to suit the requirements of the individual patient, were factors beginning to affect the demand for concentrates. The lack of a centralised purchasing system for commercial products meant that purchases could be made without central monitoring. As will appear from Chapter 21, *Haemophilia Therapy – Use of Blood Products*, returns were made to UKHCDO of the use of commercial products. But in the absence of a haemophilia register there was not a comprehensive record of all demand.

**19.90** Unless the Blood Transfusion Services and the fractionators had full knowledge of the total demand for the current groups of therapeutic products required for effective treatment of patients, and of the proportion of that demand likely to be met by commercial purchases, effective planning of the production targets and production plant and processes required by the fractionation centres was unlikely to be achieved.

**19.91** Since the commercial market to which Dr Biggs referred was largely serviced by foreign pharmaceutical companies, clinical independence and a policy of national self-sufficiency in blood products were bound to come into conflict.

**19.92** While that would have been the case in a static market environment, the added elements of technological change and changing patterns of demand would inevitably add to the complexity of the problem of servicing the market.

**19.93** Tensions between fractionators and clinicians were also inevitable unless there was a properly coordinated policy and management framework that was effective to resolve issues and implement solutions to problems as they emerged and were identified. After full commissioning of the PFC and until the 1980s; Scottish production of concentrates largely met the demands of haemophilia clinicians for NHS factor products. However, total demand for NHS products was always lower than total demand overall, since commercial purchases reflected clinicians' preferences that involved choices that were independent of the availability of the domestic product. In the longer term, if true self-sufficiency were to be achieved and maintained, additional capital investment would have been required.

**19.94** In the circumstances, it is somewhat surprising that Scottish needs were as well catered for as, in the event, they proved to be. The SNBTS's ability to meet actual demand for therapeutic products from domestic sources was sustained from 1975–76 to 1981–82, and, with the exception of the two years 1978–79 and 1979–80, when demand for clinical use exceeded the PFC's output, available supplies of PFC Factor VIII concentrate exceeded demand for concentrate estimated at average UK rates.<sup>92</sup> This outcome, however, was a reflection of the failure at UK level to realise the policy objectives formulated at the planning of the production facilities in England and Scotland. If the PFC at Liberton had been called on to meet the demands of a significant part of northern England, Scotland's domestic supplies of Factor VIII concentrate would have fallen short of demand.

## CHAPTER 20

### HAEMOPHILIA THERAPY – THE PERIOD UP TO THE EARLY 1980s

**20.1** So far as is relevant to the Terms of Reference, the early history of the administrative and management structures set up for the provision of blood services in Scotland is discussed in Chapter 17, *Blood and Blood Products Management*. Collection procedures and the provision of manufacturing facilities are discussed in Chapter 18, *Collection of Blood – General*, and Chapter 19, *Production of Blood Products – Facilities*. The use of blood products in haemophilia therapy is discussed in Chapters 21, *Haemophilia Therapy – Use of Blood Products*, and 22, *Haemophilia Therapy – Use of Blood Products 1985–1987*. These are all inter-related aspects of the background against which products came to be in use that were associated with the transmission of hepatitis and HIV. This chapter deals with the development of the products in Scotland that were manufactured, prescribed and used in the material period when patients were at risk of infection.

**20.2** The arrival of commercial concentrates in 1973 changed market conditions, and had a significant impact on the approach of the public sector producers in the UK as a whole to the production and distribution of NHS products. Coincidentally, plasma fractionation in Scotland was about to undergo very significant change with the opening of the new Protein Fractionation Centre (PFC) in Edinburgh.

**20.3** This chapter deals with developments in technology up to 1982–83. Up to that point the risk of infection, so far as it was understood, was of transmission of hepatitis, first Hepatitis B and then non-A, non-B Hepatitis (NANB Hepatitis). After that point, the reports of AIDS in haemophilia patients treated with blood products, and with no other risk factors for AIDS, brought about a significant change in the approach to factor concentrate therapy in the treatment of haemophilia. It is appropriate to deal with the periods separately. The focus in this chapter is on the development of early blood products, and, so far as related to that, the steps taken to meet demand for products for clinical use. The historical context is of some importance.

#### Origins

**20.4** The process of separation of whole blood into components for use, or further processing, already had a long history by the start of the reference period, reflecting the interaction of developing medical knowledge and technological progress. Blood is a complex mixture, including red cells, white cells and platelets, together with plasma which contains proteins, sugars, fats and a number of other smaller components such as hormones. The primary stage procedure of separation of whole blood into red cells, buffy coat (which contains white cells and platelets), and plasma depends particularly on the density differences between the corpuscular components and plasma.<sup>1</sup> Centrifugation of blood results in layering of components according to their density.

**20.5** From an early period, centrifugation was routinely performed at transfusion centres.<sup>2</sup> Initially, storage, whether of whole blood or blood components, was hampered by the coagulation that inevitably follows collection of blood from the body. Once the collection procedure begins, the blood is removed from the body's natural metabolic sustaining

<sup>1</sup> Harris, JR. *Blood Separation and Plasma Fractionation*, 1991, Wiley, New York, page 49

<sup>2</sup> *Ibid* page 6

environment, cools from body temperature, and is exposed to foreign substances.<sup>3</sup> The effective and efficient collection and storage of blood became the focus of technological research and development. Early in the twentieth century, it was discovered that various salts, and in particular citrates, in an unphysiological preservative anticoagulant solution, could maintain the fluidity of blood stored in containers. Citrate-based anticoagulants, usually with the addition of sugar, and heparin anticoagulants were developed progressively thereafter.<sup>4</sup> The blood collection procedures had to be rapid to avoid coagulation in the collection line. And the addition of the anticoagulant solution had to be prompt to prevent the development of foci of coagulation in the collection pack. Sterile disposable plastic pack assemblies introduced in the 1950s to replace glass bottles in the collection of blood donations provided for the easy introduction of the appropriate anticoagulant solution.<sup>5</sup> Once bagged, the material had to be stored at the appropriate temperature, depending on the purpose for which the components were required.<sup>6</sup> Centrifugation of the blood in plastic bags later provided the starting materials for further processing.<sup>7</sup>

**20.6** Three constituents of plasma were to become material to the development of therapeutic products: (i) the clotting factors, including fibrinogen and Factors VIII and IX; (ii) albumin, a normal protein in the blood which has oncotic properties and acts as a carrier protein for other substances; and, importantly, (though not directly relevant to the Terms of Reference) (iii) immunoglobulins (Ig), needed to boost antibodies in the blood of hypogammaglobulinemia patients, or patients who have suffered a needle stick injury, for example, to help fight off viral infections.<sup>8</sup>

**20.7** Refrigerated plasma was used clinically at or near the point of collection. Scientific developments in cryobiology enabled the storage of components for periods far greater than the point at which degradation would have occurred naturally in refrigerated materials. Typically, and with limited exceptions, plasma donations that were not required for immediate local clinical application were cooled rapidly and frozen. Fresh frozen plasma was retained for therapeutic application. Later, outdated stock was used for further processing. But at this early stage, it was used in the form in which it was separated immediately after the point of collection.

**20.8** It is important to note that plasma, fresh or fresh frozen, was simply a component of the donor's blood as collected, untreated and unprocessed. It inevitably carried with it all of the proteins, including virus particles, circulating in the donor's blood. The risk of transmission of virus infection reflected the prevalence of infection in the donor population, unaffected by the processes by which it was extracted.

### Early developments in process technology

**20.9** Early technological developments did little to change that risk. Plasma filtration, introduced in August 1941, dealt with bacterial contamination.<sup>9</sup> Freeze-drying, introduced at the Royal Infirmary of Edinburgh (RIE) in 1943, made plasma available as a powdered product that could be re-constituted at the point of use.<sup>10</sup> The technology was to be

<sup>3</sup> Ibid pages 48–49

<sup>6</sup> Ibid page 44

<sup>7</sup> Ibid page xi

<sup>8</sup> Dr Cuthbertson – Day 46, pages 2–3

<sup>9</sup> See Chapter 17, *Blood and Blood Products Management*, paragraph 17.9

<sup>10</sup> Ibid paragraph 17.10

important in the development of factor concentrates, but in isolation did not alter the risk of transmission of infection.

**20.10** Efforts to produce factor concentrates began in the 1950s and progressed during the 1960s.<sup>11</sup> Before the reference period two procedures were developed in relation to the processing of plasma that became significant: fractionation and the preparation of cryoprecipitate. Two scientists achieved prominence for developing the fractionation technology applied in isolating specific proteins from blood plasma for clinical application, Professor Edwin J Cohn, a professor of biological chemistry at Harvard University Medical School, and Professor RA Keckwick of London. Both before and during the reference period Scottish scientists followed the Cohn methodology as it was developed from time to time, and this chapter therefore describes that methodology and its derivatives.

**20.11** The processes adopted in fractionating plasma reflect in part the complexity of blood. The components of blood do not withstand heating, for example, to a common degree. Red cells are contained within a membrane that starts to disrupt at about 40°C, and the components then clot. Platelets and white cells are similarly susceptible to temperature increases. The fluid component of blood – the plasma proteins, fats and sugars – can be heated, but still if heated together are subject to denaturation: they fall apart. Clotting begins, but at different temperature ranges from the cellular components. It is not possible to treat whole blood with heat. The characteristics of each component require to be taken into account separately in developing a heat treatment strategy.<sup>12</sup>

**20.12** The manufacture of blood concentrates depends on the chemical and physical characteristics of proteins contained in blood plasma. Plasma proteins vary in solubility when exposed to differential conditions of pH, ethanol concentration, temperature, ionic strength, and protein concentration. Professor Cohn and his colleagues showed that plasma proteins could be separated and partially purified in a reaction medium in which hydrogen ion concentration, ionic strength, temperature, protein concentration, and the amount of added ethanol were all carefully controlled.<sup>13</sup> A series of fractionation steps was devised for the major biological categories of plasma proteins: these were partitioned as precipitates or supernatants after each manipulative stage.

**20.13** The method was known as cold ethanol fractionation. Cohn fractionation exploited the physical changes induced in the frozen plasma by thawing under controlled conditions. When frozen plasma was immersed in a water bath at 4–6°C, thawing produced a liquid component (the supernatant) which could be extracted, leaving an illiquid residue. The Cohn process resulted in five stages of precipitation, the plasma ‘fractions’, which produced a range of derivatives for clinical application. Fraction I contained fibrinogen and antihæmophilic globulin (AHG, later known as Factor VIII), which was used to treat hæmophilia, Fraction III contained most of the lipid bearing  $\beta$ -globulins, and Fraction V contained albumin, which was used as a plasma substitute.<sup>14</sup> The plasma fractions were then removed by filtration or centrifugation.<sup>15</sup>

**20.14** With later discoveries concerning the various clinical states in which deficiency in one or other of the blood constituents was the causative pathological abnormality in patients, the possibilities of specific remedial therapy became evident. The development of the Cohn fractionation scheme, which demonstrated that plasma could be split into various different components (each of which had different clinical properties), provided the basis for manufacture of a wide range of human blood products.<sup>16</sup> Process technology developed to exploit these characteristics of plasma.

**20.15** In the period between 1940 and the reference period of this Inquiry, scientists pioneered the use of a range of chemical additives during the manufacturing process which modified the Cohn ethanol fractionation procedure, resulting in Factor VIII concentrates of varying purity, a function of the removal of other proteins such as fibrinogen and fibronectin from the original Fraction I. By 1970, depending on the chemical agent introduced, low purity, intermediate purity, high purity and very high purity concentrates of Factor VIII could be produced, although the composition and structure of Factor VIII were not then known.<sup>17</sup>

**20.16** By 1972, the Cohn fractionation process had undergone many modifications. So far as is material for the purposes of this Report, it had been discovered at a very early stage in Cohn's work that Fraction I contained fibrinogen and AHG. But alcohol precipitation alone did not provide the range, quantity and purity of concentrates of coagulation factors that scientific research was making available for clinical application.<sup>18</sup>

**20.17** Professor Alan Johnson of New York, with Dr Margaret Karpatkin and Dr Jack Newman published a method for large-scale production of concentrates in 1969.<sup>19</sup> A further paper on the method was published in 1971.<sup>20</sup> It came to be known as the 'Newman' method. The supernatant plasma from which precipitates had been prepared using this technology was a source of Factor IX.<sup>21</sup> The Newman method was to become the basis of the processes for the production of protein factor concentrates adopted in Edinburgh.<sup>22</sup>

**20.18** Professor Johnson's 1971 paper described methods for the production of Factor VIII concentrates of intermediate and high purity. The paper traced the developments in technology based on increasingly sophisticated precipitation methods using chemical additives. They had published, in 1966 and later years, papers describing methods of producing clinically effective intermediate purity Factor VIII concentrate by simultaneous ethanol- and cryo-precipitation of Factor VIII from melting fresh-frozen plasma and adsorption of Factors II, VII, IX and X from the precipitate. The step forward in the 1971 paper was the introduction of polyethylene glycol (PEG) in the precipitation of intermediate purity concentrate, resulting in a concentrate purified 125 to 350-fold which was effective in the treatment of haemophilia patients. The technology could be adapted to large-scale production. The paper gave wide circulation to the methodologies involved.<sup>23</sup>

<sup>23</sup> Preliminary Report, paragraph 1.44

**20.19** The Cohn/Newman method was used throughout the USA and in parts of Europe.

**20.20** Viewed as a whole, the method produced progressively depleted plasma by extracting intermediate materials, in each case a solid, suitable for the specified final products, and a liquid supernatant.<sup>24</sup> At the end stage of the original Cohn process a residue was left from the progressive thawing of frozen plasma, and the adsorption of proteins from the supernatant. The residue was slow to re-dissolve, and was initially discarded.<sup>25</sup>

**20.21** In 1959, before the refinements to the Cohn methodology described above had been introduced, Dr Judith Pool and her US colleagues had discovered that the residue left by Cohn fractionation, which remained at low temperature after drawing off the liquid produced in the thawing process, contained a high concentration of fibrinogen and Factor VIII, antihæmophilic activity. The residue also contained von Willebrand's Factor and other proteins, including fibronectin.<sup>26</sup> In 1964, Dr Pool described a method of producing these concentrated factors from plasma by freezing which was quite independent of the need for Cohn fractionation.<sup>27</sup> This was followed in 1965 by the publication by Pool and Shannon of further developments in the technology.<sup>28</sup> The product was named cryoprecipitate.

**20.22** The process devised by Dr Pool and her colleagues separated plasma from the red cells in whole blood donations by centrifugation at 4°C as soon as possible after collection, in the normal way, using standard compartmented plastic bags. The tubing connecting the compartments of the bag was clamped. The satellite bag containing the plasma was fast frozen. The whole bag was then refrigerated for cold-thawing of the frozen plasma. When thawed to only a few degrees above zero, and typically to 4°C, fibrinogen precipitated as a 'sludge' containing much of the Factor VIII content of the plasma.<sup>29</sup> The temporary clamps were removed, and the supernatant plasma was allowed to return to the red cell bag. The bags were separated, and the cryoprecipitate frozen for storage pending use. The process did not produce mutually exclusive components. Red cells used in clinical practice contained very small amounts of plasma. Platelets were suspended in plasma. Each had the potential to transmit infection.<sup>30</sup> However, the Pool and Shannon method produced a cryoprecipitate that was high in Factor VIII content, and that was stable and soluble.<sup>31</sup> This provided a relatively purified form of Factor VIII for hæmophilia therapy. Attempts had been made to isolate Factor VIII for clinical use in the treatment of hæmophilia in the 1930s.<sup>32</sup> But only now was there a relatively straightforward and effective procedure.

**20.23** Cryoprecipitation of Factor VIII from single units of fresh-frozen plasma was viewed as a simple, practical procedure that could be carried out by any blood bank.<sup>33</sup> It was used by blood transfusion centres in many countries and throughout Scotland. The single

<sup>32</sup> *Ibid* [SGF.001.1913]

<sup>33</sup> *Ibid* [SGF.001.1913]

cryoprecipitate units might thereafter be pooled for further processing,<sup>34</sup> but typically were used in multiples to make up a dose for Haemophilia A therapy. The product had lower coagulant activity than the material produced by Cohn Fraction I. But it was inexpensive to produce and the deficiency in coagulant activity could be made up by processing extra plasma.<sup>35</sup> However, in this application, the method depended on prompt processing after collection, when coagulant activity was high, and new technology was required to process plasma on a large scale. This became the principal approach to the research and development of plasma processing in Glasgow in the early years of the reference period.

**20.24** When cryoprecipitate from 10–15 individual plasma donations was combined and given to the patient it was possible to raise the Factor VIII level sufficiently to stop haemorrhage. During the late 1960s this treatment became available to haemophilia patients at hospitals on an out-patient basis. This was a major therapeutic advance for the treatment of Haemophilia A. Because cryoprecipitate does not contain very much Factor IX it was unsuitable for the treatment of Haemophilia B.<sup>36</sup>

## Haemophilia B

**20.25** Treatment of patients with Haemophilia B was initially with fresh-frozen plasma. Until 1967 that was the only treatment available for correction of deficiencies in coagulation Factors II, VII, IX and X. In 1967, the PFC began making PPSB,<sup>37</sup> a plasma derivative first produced in 1959 by Jean-Pierre Soulier in Paris for treatment of Haemophilia B patients. The demand for PPSB, which proved to have wide-ranging application, prompted research in Edinburgh into new methods of recovering Factor IX from the normal citrated plasma used in Cohn fractionation. The research, by Middleton, Bennett and Smith of the PFC, led to development of a Factor IX product, based on ion exchange purification.<sup>38</sup>

**20.26** In a similar fashion to Factor VIII, it had as its aim the production of a finished product with a specified amount of Factor IX activity per vial which would be suitable for home therapy and which would comply with the specifications of the British Pharmacopoeia (the UK standards for medicinal products).<sup>39</sup> The product known as 'DEFIX' was produced at the PFC from 1972.

**20.27** In the fractionation process, Factor IX was extracted downstream of Factor VIII, and it is appropriate to postpone discussion of Factor IX at this stage.

## Blood product development and production in Scotland

**20.28** The general trends in use of blood donations were followed in Scotland. Red cell preparations, including concentrates, were isolated. Platelet and leukocyte concentrates were derived from processing the buffy coat isolated in the primary separation procedure. As the twentieth century progressed, these operations superseded the use of whole blood for therapeutic purposes. The further processing of plasma became the principal

<sup>39</sup> Dr Foster – Day 41, page 52

downstream procedure of interest for present purposes. Developments in the production and use of cryoprecipitate were pursued in Glasgow and the west of Scotland, latterly centred on laboratories at Law Hospital. In Edinburgh and the South East of Scotland Region of the Blood Transfusion Service the emphasis came to be on fractionation.

**20.29** The development of the first Factor VIII concentrate by the SNBTS was based on information obtained from Dr Cohn's laboratory in the early 1950s by Dr Drummond Ellis, then Head of the Regional Blood Transfusion Centre and Blood Products Unit (known until 1970 as the 'BPU'), at the RIE, where Edinburgh and South East Scotland Blood Transfusion Service was based.<sup>40</sup> Dr Ellis later moved to the Blood Products Laboratory (BPL), Elstree, and was succeeded by Mr John Watt.<sup>41</sup>

**20.30** The early history of development work in the east of Scotland was described in an article published in 1965: *Red Cell Banking and the Production of a Factor VIII Concentrate* by Dr Cumming, Dr Ellis and Mr Grant of the BPU.<sup>42</sup> Scotland's first fractionated plasma product was normal immunoglobulin for the prevention of measles, produced in 1952 at the RIE laboratory.<sup>43</sup> Production of fibrinogen followed in 1956. Experimental quantities of Cohn Fraction I were made between 1952 and 1956.<sup>44</sup> Routine production of an early version of Factor VIII known as antihæmophilic factor or AHF (from Cohn Fraction I) followed in 1956 and albumin in 1965.<sup>45</sup> At this early period, the production of immunoglobulins was a significant part of the BPU's operations. A new pilot plant for fractionation was established at the BPU at the RIE in 1968.<sup>46</sup> Cohn Fraction I, relatively rich in Factor VIII (antihæmophilic globulin) activity was produced there until production moved to the new facility built at the PFC, Liberton.

**20.31** The fractionation process developed at BPU was initially very small-scale, as was the equivalent NHS process in England, and Factor VIII concentrates manufactured by the public service providers were available in very limited quantities. In Edinburgh, each bottle of Cohn Fraction I product was derived from six bottles of fresh plasma, the number of bottles that could be accommodated in one centrifuge load. Only one batch could be processed in a week. Dr Cumming and his colleagues reported, however, that it appeared from their results that it was possible to prepare a safe and reasonably active Cohn Fraction I from plasma, provided that suitable precautions were taken during processing.<sup>47</sup> The similar Factor VIII preparation used in England and Wales during the 1960s was referred to as 'NHS freeze dried factor VIII concentrate' by Dr Rosemary Biggs.<sup>48</sup>

### Product range in 1973

**20.32** So far as plasma products are concerned, the discussion in this report necessarily focuses on the production of factor concentrates and their use in haemophilia therapy. But it is important to note that, especially up to the beginning of the reference period, this bias gives a false impression of the scope of operations of the Blood Transfusion Services

<sup>40</sup> For details of the history of the PFC and work carried out at the RIE see paragraphs 5.6– 5.20 of the Preliminary Report.

and of the manufacturing facilities. Dr James Smith said of the period before he moved to Oxford, in 1975:

This Inquiry focuses on haemophilia but at no time during these years were we able to neglect the many, many more patients who required immunoglobulins, albumin and other products, which we did not have the right to interfere with too much. These patients were more diffuse in their needs and the clinicians who used these products were scattered. So there was no, if I can call it, pressure group from patients with immunodeficiencies, for instance .... We all had to take account, equal account, of all the users of our products.<sup>49</sup>

**20.33** In a personal assessment of needs dated 12 June 1973, Mr Watt analysed the demand for plasma, drawing on a wide range of information. He wrote:

Discussion on the probable need for plasma for fractionation indicates that, of all fractions prepared, the main limiting consideration is the need for Plasma Protein Solution.<sup>50</sup> The need for specific immune globulin and salt poor albumin will create errors in calculation but, in a coherent policy of overall balanced use of blood and its fractions, these errors practically cancel each other out to make a net error factor of less than 1% in the total estimate.<sup>51</sup>

**20.34** In his view, at that time, if plasma requirements for plasma protein solution (PPS) or stable plasma protein solution (SPPS) could be met, the supply of plasma would be sufficient for other fraction production. In particular, the amount of plasma, 200,000 litres or 1 million donations, required for AHG (antihaemophilic globulin) preparation was 'of no account in consideration of overall need'.<sup>52</sup> The critical figure was the 400,000 litres required for PPS. At that stage the PFC had process potential to handle up to 300,000 litres of plasma per year, but could not finish PPS at equivalent rates.<sup>53</sup>

**20.35** Leaving aside questions of projected demand in numerical terms, the balance between AHG and PPS needs reflects Mr Watt's assessment that the principal driver of demand for plasma products in 1973 was the need for albumin, specifically PPS.

**20.36** It is possible that the paper may have been, in part, an attempt by Mr Watt to respond to controversy that had developed within the SNBTS relating to developing technologies. There were some significant differences of opinion over the development of plasma products. As already noted, two processes for the production of Factor VIII products had developed, resulting in different products each of which sought to compensate for low Factor VIII levels in the patient's blood. Each allowed reliable Factor VIII treatment, when applied appropriately. Some experts favoured the use of cryoprecipitate, as for example in Glasgow. From around 1968, refinements in Cohn fractionation led to a product of comparable potency in Factor VIII activity which was easier to use, but which involved increased demand on the scarce resource of plasma.

---

<sup>49</sup> Dr Smith – Day 59, page 8

<sup>50</sup> SPPS, Stable Plasma Protein Solution, is an albumin product of slightly lesser purity than the product competently described as Albumin in terms of the British Pharmacopeia.

<sup>51</sup> Watt JG, *Plasma fractionation in the United Kingdom – a personal appraisal* (Draft) 12 June 1973 [SNB.010.1991] at 1993

<sup>52</sup> *Ibid* at 1996

<sup>53</sup> *Ibid* at 1997

**20.37** The controversy was explicit at a joint symposium held on 4 February 1972 by the Royal Society of Edinburgh and the Royal College of Physicians. Professor Cash (then Deputy Director of the Edinburgh and South East Scotland BTS) reflected one view:<sup>54</sup>

One of the disquieting trends in the last few years has been the energetic activities of the protein chemists. On the basis of the clinical desirability for a small-volume high factor VIII content product, techniques have been developed which go a long way towards this end .... The serious drawback in this work is the high production losses. The shortage of raw material for the treatment of all haemophiliacs at the present time is such that until comparable yields are obtained the production of this type of product should be actively discouraged, or at least strictly controlled and its use limited to a small group of patients, such as those with acquired inhibitors.

**20.38** At that stage, in 1972, Mr Watt and colleagues from the PFC (as the BPU had now been re-named) had reservations about the stage technological development had reached. At the symposium they commented that the Newman method was promising, but that it lacked the clinical data necessary to support its effectiveness.

**20.39** However, opinion was to change rapidly. Mr Watt had met Dr Johnson in Australia in 1966, and as a result the PFC was provided with advice from Dr Johnson when Mr Watt joined the PFC the following year.<sup>55</sup> Dr Johnson's 1971 paper was not referred to in the symposium presentation by Mr Watt and his colleagues. It was to provide the methodology for Factor VIII preparation adopted in Scotland.<sup>56</sup> In the course of the reference period, close collaboration developed between the SNBTS and Dr Johnson's team.<sup>57</sup> For present purposes, the development of the new PFC at Liberton, Edinburgh, and the adoption of the Newman method there, marked the move towards commercial-scale production of factor concentrates in Scotland.

**20.40** The incentive to produce factor concentrates was described by Dr Peter Foster:

They were more potent, defined and purified than cryoprecipitate; they could be filtered to remove bacterial contaminants and had a lower incidence of allergic reactions than cryoprecipitate. In contrast to cryoprecipitate they were also amenable to large volume manufacture compliant with good pharmaceutical manufacturing practice (GMP). The fact that they were freeze dried also made them easier, quicker and more convenient to use than cryoprecipitate, which had to be stored frozen. Crucially, they enabled patients to treat themselves at home, giving people with haemophilia access to education and employment which had not previously been possible.<sup>58</sup>

**20.41** Mr Watt wrote a report (with the assistance of Dr Smith) on the 'Development of Factor VIII concentrates' in December 1973.<sup>59</sup> The paper focused on the transition from the production of Fraction I, antihaemolytic factor, into the start of the new era of production of more potent concentrates inspired by Johnson and Newman.<sup>60</sup> He described recent

<sup>60</sup> Dr Smith – Day 59, page 14

developments. In the latter part of 1972, laboratory-scale batches of plasma, 2–10 litres, were fractionated by the method of Newman and Johnson to intermediate potency Factor VIII. In February 1973, they progressed to the 10–60 litre scale. By the date of his report, a product of intermediate type had been expanded to 100-litre scale and was obtaining 30–40% yield. The report stated:

Large scale crushing and thawing equipment was commissioned in early September 1973, and is functioning adequately on a load of 100 [litres] plasma. It is expected that with minor improvements the batch size may be increased to 180 [litres].

**20.42** Cohn Fraction I was produced until the quarter ended 27 September 1974. In the quarterly report for that period it was noted:

This is the last occasion on which A.H.F. (Cohn Fraction I) will appear in these reports. The ... old item (Cohn Fraction I) will not appear after this quarter.<sup>61</sup>

**20.43** By this time, the PFC employed a small volume computer-controlled continuous fractionation process invented by Mr Watt. This contributed to the increased throughput possible at the RIE in the last phase of operation of the facility there, and it was to promote considerably larger-scale production of concentrates after the move to Liberton. Until the move, however, factor concentrate production in Edinburgh remained a small-scale operation, and already exposed the market to imported products as discussed in Chapter 21 *Haemophilia Therapy – Use of Blood Products*.

**20.44** A report to Area Health Boards set out the position as at 6 January 1975:

It is not possible to overlap production at the Royal Infirmary and Ellen's Glen as the computer has been moved to the latter and hence there will be an interim period, as the new plant is tested and brought into production, when the supply of blood products will be reduced. The length of this interim period will depend on the rapidity with which the new plant can be brought into full production; there are many novel features in its design and all must be thoroughly tested.<sup>62</sup>

**20.45** In the Inquiry's Preliminary Report an attempt was made to reflect trends in production by reference to a selection of data from annual reports of the SNBTS which appeared to show that the production of anti-D immunoglobulin and SPPS was more significant than the production of AHF as the PFC at Liberton came on stream (consistent with Mr Watt's approach to calculating production targets for the new facility<sup>63</sup>). In response to the Preliminary Report, the SNBTS observed that it was unclear what the figures represented as no units had been given. That criticism is accepted. However, with limited exceptions, the source material, SNBTS data, did not specify the units applicable to the several products listed.<sup>64</sup> The disruptive effect of the move on concentrate production is illustrated in Chapter 21, *Haemophilia Therapy – Use of Blood Products*, Figure 21.5

<sup>61</sup> PFC Report on production of plasma fractions for quarter ended 27 September 1984 [SNB.010.3712]

<sup>62</sup> Maj. Gen. Jeffrey's letter of 6 January 1975 to Chief Administrative Medical Officers [SGH.007.7009]

<sup>63</sup> See Chapter 19, *Production of Blood Products – Facilities*, paragraph 19.15

<sup>64</sup> For example, the information recorded for 1975–76 in the SNBTS Annual Report, Appendix 2, provided comparative data for 1964–65 [SNB.010.3921] at 3957. No units were specified for Fibrinogen, Normal Immunoglobulin, or SPPS. Units were specified for Anti-D and Anti-Tetanus, and for II, VII, IX, X combination products only.

**20.46** The production of intermediate Factor VIII fell from its 1972–73 level as preparations were made to transfer to the PFC facility. Leaving aside comparisons between products, Anti-D and SPPS production fell to a more limited extent in 1973–75, the construction and commissioning phase. The rapid build-up of production of Factor VIII concentrate after commissioning of the PFC reflected a change of emphasis in production towards meeting the demand for products for haemophilia therapy.

### **Technology after the Protein Fractionation Centre moved to Liberton**

**20.47** There were major changes in the technology employed in the PFC at Liberton at or about the beginning of the reference period and continuing throughout the period dealt with in this chapter. They were generally related to increasing process capacity and efficiency, but included work aimed at the removal of virus from concentrates. Although the PFC's Factor VIII concentrate processes were based on Dr Johnson's work, scientists at the PFC contributed to the development of process technology over the period covered in this chapter, internally and in collaboration with Dr Johnson.

**20.48** As at April 1975, Dr Foster, then Head of Research and Development at the PFC, wrote a summary report on research and development work in progress.<sup>65</sup> A wide range of projects, begun on various dates from 1970, were described. The report indicated that there was about to be a step change in the volume of production of Cohn fraction products. A basic continuous fractionation unit, with semi-automatic computer control, would be commissioned at the new facility. It would give a processing capability of at least 2000 litres a week for SPPS. Extension of the system to other PFC products was being evaluated and was expected to allow process optimisation in terms of yield, purity and daily work schedules and an increase in throughput. The development of Factor IX products was in hand. The evaluation and re-design of the Factor VIII systems and processes were also in hand for the production of intermediate Factor VIII concentrate. The use of sonic vibration for precipitate conditioning was being studied with a view to improving centrifugal separation, particularly in continuous processing.

**20.49** Two significant aspects of this work were continuous processing, and precipitate conditioning. Dr Foster commented that precipitate conditioning had always formed an important part of fractionation, but that little information had been published on the subject, and the physico-chemical changes involved had not been identified. Significant advances in centrifugal separation in continuous processing were anticipated, along with gains in general knowledge of plasma fractionation and protein isolation.

**20.50** The SNBTS followed up the topics: by early 1976 it was becoming apparent that there might be an increase in demand for fractionation. A report was prepared in January 1976.<sup>66</sup> Dr Johnson had been involved in discussions in November of the previous year. Length of storage of frozen plasma for fractionation was considered. The use of polyethylene glycol to enhance Factor VIII recovery and of heparin to stabilise plasma were to be studied. The design of a continuous thawing system to produce more granular cryoprecipitate was in hand. The PFC's Factor VIII products were known as 'NY' between late 1979 and late 1984 to reflect the collaboration with New York University (and Dr Johnson in particular).<sup>67</sup>

**20.51** For the fractionator, yield of Factor VIII activity was important, and the balance between purity and yield was vital. When the Edinburgh scientist Dr Duncan Pepper<sup>68</sup> applied for a research grant on 15 June 1978,<sup>69</sup> the specified areas of interest were Factor VIII stability and yield. Edinburgh research had dealt with methods of maximising the rate of thaw of frozen plasma within the constraint imposed by Factor VIII solubility, and the use of sophisticated mixing and temperature control systems using a thaw-siphon technique. Blocks of frozen plasma were crushed to increase the surface area over which heat was applied. By continuously removing the thawed plasma, below the solubility temperature of the Factor VIII component, over a wide area of plasma 'snow' produced by crushing, dissolution of the Factor VIII was avoided and the degree of Factor VIII degradation was reduced. It was said that the surface area factor had been ignored by others. The design of processes for crushing and continuous thawing, using fluid removal for temperature control, became one of the defining features of research and development work at the PFC for a considerable time. Dr Foster published a poster presentation and abstract of their work at the Seventh International Congress of Thrombosis and Haemostasis, London, in July 1979. The emphasis within the PFC on techniques for large-scale plasma thawing for the recovery of cryoprecipitate Factor VIII continued.

**20.52** In the end, not all of the developments proposed by Dr Johnson were taken up universally. Dr Smith commented that the higher purity concentrate using polyethylene glycol and glycine never gained wide use, and was not continued beyond initial experiments in Edinburgh.<sup>70</sup>

**20.53** It is not necessary to trace all of the developments in technology in this period for the purposes of this report. The manufacturing process became complex and highly defined. The emphasis was on technological improvements in processing raw materials to increase efficiency in the production of an intermediate purity concentrate, while meeting demand for other blood products such as immunoglobulins and albumin products, particularly SPPS.

**20.54** A statement was provided by Dr Foster which includes a narrative of the various manufacturing steps along with simplified flow diagrams as at the end of 1983. (See Figures 20.1, 20.2 and 20.3 at the end of this chapter for the flow diagrams.) Dr Foster had also earlier supplied a floor plan of the ground floor of the PFC,<sup>71</sup> a series of photographs detailing elements of the fractionation process<sup>72</sup> and a film of the process made in 1995, which was viewed on day 41 of the public hearings.<sup>73</sup>

**20.55** A total of 17 steps were needed in order to achieve a finished product with a specified amount of Factor VIII activity per vial, starting from frozen plasma which the PFC received from the SNBTS. They were described in some detail by Dr Foster as at the end of 1983 in response to a request by the Inquiry<sup>74</sup> and were discussed at length during Day 41 of the Inquiry's hearings.<sup>75</sup> The aim was to create a product which would be suitable for home therapy and which would comply with the specifications of the British Pharmacopoeia.

<sup>68</sup> Dr Pepper was at that time Principal Scientific Officer, SE Scotland BTS.

<sup>75</sup> Dr Foster – Day 41, pages 22–55

**20.56** The process began with ‘plasma conditioning’ by bringing the frozen plasma delivered to the PFC from minus 40°C to a temperature of about minus 15 to minus 10°C. Batches of 4000 donations each were processed at the rate of about two per week.<sup>76</sup> The plasma was then stripped from its plastic containers, crushed in a hammer mill, and thawed as quickly as possible to recover cryoprecipitate particles for processing.<sup>77</sup> The plasma had to be thawed at a temperature that avoided the particles of cryoprecipitate from being dissolved.

**20.57** The crushed plasma ‘ice’ was discharged continuously into a cylindrical thawing vessel which heated the ice to just above its melting point, and released melted plasma, containing particles of cryoprecipitate, to drain by gravity into a holding vessel. From there, the material was pumped to a centrifuge where cryoprecipitate particles were accumulated on the walls of the vessel, and the clarified liquid supernatant drained into a collection vessel for further processing. The cryoprecipitate was used to make Factor VIII and the cryo-supernatant was used to make Factor IX.<sup>78</sup>

**20.58** Continuous thawing was a major advance on previous technology which had depended on thawing in small-volume batch tanks, and in changing temperature conditions. It enabled plasma throughput to be increased relatively easily.<sup>79</sup> In comparison with the superseded batch thawing method, the yield of Factor VIII activity was increased by about 50%.<sup>80</sup> Solubility was enhanced, and in due course this enabled the product (NY) to withstand dry heat treatment at 68°C for 2 hours without further process modification.

**20.59** The use of continuous thawing was devised by the SNBTS and published in 1978.<sup>81</sup> It was introduced for routine production in August 1979, and progressed to faster production with upgraded equipment in January 1981.<sup>82</sup> The improvements were reported in 1982.<sup>83</sup>

**20.60** After centrifugation, the cryoprecipitate was rinsed in a 2% solution of ethanol at 2°C to remove any residual plasma which might contain potentially damaging substances. The rinsed cryoprecipitate was suspended in a buffer solution which was designed to protect the material from chemical shock as processing continued to dissolve most of the cryoprecipitate whilst excluding material that was poorly soluble.<sup>84</sup> The pH of the solution was adjusted to pH 7.0, the optimum pH for the recovery of Factor VIII, by the slow addition of dilute hydrochloric acid.

**20.61** At this stage a residue of unwanted coagulation factor proteins remained in the cryoprecipitate, including other coagulation factors (Factors II, VII, IX and X) which had not been removed by the thawing process, as well as impurities which could otherwise cause the Factor VIII to become unstable. These were known to bind preferentially to aluminium hydroxide [Al(OH)<sub>3</sub>] and a stable gel of that material was introduced to remove them. This

occurred by adsorption of the unwanted materials, leaving the Factor VIII in solution. The aluminium hydroxide gel and the adsorbed materials were then separated from the main solution by centrifugation in bottles, and the supernatant solution was decanted from the bottles into a sterile pressure vessel for filtration through a series of successively finer filters.

**20.62** An anticoagulant, tri-sodium citrate, was then added to prevent de-stabilisation of the Factor VIII by any residual activity from trace levels of coagulation factors other than Factor VIII. The pH was adjusted to pH 6.8 with dilute hydrochloric acid. Further filtration with even finer filters followed.

**20.63** The final Factor VIII solution was then dispensed into sterile glass vials using an automated aseptic dispensing system. The amount of Factor VIII dispensed was less than the capacity of the glass vial so that patients could add distilled water to the final freeze-dried product. Each vial was fitted with a raised stopper with small grooves in the side to allow moisture to escape from the vials during freeze-drying. The products were frozen solid, and then dehydrated by freeze-drying.

**20.64** Overall, the process to this stage took around one week. Three to four months were then needed for inspection, labelling and other procedures before the batch could be released for use.<sup>85</sup>

## Factor IX

**20.65** The manufacture of DEFIX was also described in depth in Dr Foster's statement on manufacturing.<sup>86</sup> The process was also discussed during Day 41 of the Inquiry's hearings.<sup>87</sup> A total of 17 additional steps were involved after the removal of the cryosupernatant from the cryoprecipitate. Ion exchange technology was used to separate Factor IX and related proteins from a supernatant containing immunoglobulin and SPPS/albumin. The cryosupernatant was prepared for ion exchange by use of sterile, pyrogen<sup>88</sup> free water at 4°C and adjustment of the pH to 6.9. Ion exchange gel was added and Factor IX and related proteins became attached to the gel. The separation was achieved by centrifugation. The ion exchange gel and adhering proteins were suspended in a buffer 'wash' solution for ease of pouring into a chromatography column.

**20.66** The wash solution was allowed to drain from the column, leaving the ion exchange gel and its bound proteins as a squat column. In a process known as elution, the chromatography column was flushed with a buffer solution containing sodium chloride and other sodium compounds until the coagulation factors were observed to begin emerging from the column, detected by a sharp rise in the conductivity of the solution at the column's out-flow. Various different 'eluates' or fractions were collected in containers. The fractions which met the requisite specifications for Factor IX activity and non-thrombogenicity were then thawed, in sealed containers, at room temperature. When thawed, the containers were opened, the selected fractions pooled and samples taken of Factor IX activity. After that, the solution was diluted, if necessary, to achieve a target Factor IX potency of 34 IU/ml. Filtration to 0.22 micrometres followed, as in the

case of Factor VIII, and the solution was dispensed aseptically into glass vials, which were then frozen in the same manner as outlined for Factor VIII above.

**20.67** Two of the steps common to the processes were to become significant at a later period: plasma conditioning and continuous thawing.

### **Virus research at the Protein Fractionation Centre in the 1970s**

**20.68** The processes for Factor VIII and Factor IX production so far described were the result of extensive research and development, much of it involving innovative science and technology. The removal of unwanted proteins at successive stages of the programme probably removed virus particles incidentally in the preparation of the concentrates prepared for clinical use. But they did not provide for the inactivation of any residual virus particles remaining in the final product. The products remained potentially infective in clinical use. Subject to any parallel developments in virus inactivation that were achieved, increases in the efficiency of process technology, leading to increased production capacity and output, necessarily increased the exposure of patients to risk. Until 1975 at the earliest, the known risk was of transmission of Hepatitis B. Blood donations were screened with increasing efficiency, so that the plasma received for fractionation became less likely to carry virus. For immediate purposes, the focus is on fractionation technology and the steps taken to reduce risk in processing. Virus inactivation by heat treatment is discussed in greater detail in Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*.

**20.69** In the 1970s, researchers at the PFC were active in exploring the physical removal of the Hepatitis B virus by precipitation of the virus using polyethylene glycol (PEG) as part of the Factor IX production process.<sup>89</sup> The research was part of the 'Supernine Project', a collaborative exercise with Dr Johnson and other scientists at New York University, which aimed to replace the PFC's standard DEFIX product for Haemophilia B with a concentrate that would be three to five times more potent, and have a reduced risk of transmitting Hepatitis B.<sup>90</sup> The US part of the project ultimately ran into funding difficulties when the USA National Institute of Health refused an application for further chimpanzee studies.<sup>91</sup> These funding difficulties meant that research could not be continued to assess whether the process was successful in removing Hepatitis B infectivity.

**20.70** Another part of the project involved an assessment of possible thrombogenic reactions connected to the new Supernine product, a known complication of the use of Factor IX therapy.<sup>92</sup> A team at the PFC led by Dr Foster demonstrated that the PEG processing used in an advanced form of the product reduced the amount of thrombogenic material present.<sup>93</sup> Supernine was ultimately never released for clinical use as the Medicines Control Agency were reluctant to issue a second Factor IX licence. But the work on thrombogenic reactions was of continuing benefit.

<sup>91</sup> Ibid

<sup>92</sup> See Cash et al, 'Studies on the Thrombogenicity of Scottish Factor IX Concentrates in Dogs', *Thrombosis et diathesis haemorrhagica*, 1975; 33:632 [LIT.001.0959]; and Dr Foster – Day 41, page 99

<sup>93</sup> See Foster et al, 'Thrombogenicity of Factor IX Concentrates and Polyethylene Glycol Processing', *Thrombosis Research*, 1980; 17(1–2): 273–9 [LIT.001.0208]; Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1441; and Dr Foster – Day 41, pages 100–101

**20.71** In February 1982, Dr Alex MacLeod, PFC, conducted a series of experiments in the pasteurisation of PFC's intermediate Factor VIII product with a view to inactivating NANB Hepatitis virus. It was found that if the standard product was diluted in its normal reconstituted volume, heating resulted in clotting. However, they found that if the product was diluted in the presence of certain stabilisers, the product could be heated at 60°C in a water bath and remain fluid, though becoming cloudy. It was concluded at that time that the ability to pasteurise Factor VIII concentrate was linked to purity, and that a high purity product would be required for effective treatment. The project did not progress further at that stage. But, once more, research had provided information that would prove to be of value later in the 1980s.

**20.72** The PEG precipitation method was not applicable to Factor VIII because the sizes of the Factor VIII complex and the virus molecule were not sufficiently different for effective separation by the process technology developed at the time.<sup>94</sup> In his report dated December 1973,<sup>95</sup> Mr Watt included in his narrative of candidates for investigation the use of specific solid-phase polyelectrolytes in a procedure for the purification of Factor VIII. The procedure had been developed by Dr Johnson. It exploited a characteristic of Factor VIII which resulted in the protein attaching preferentially to the polyelectrolyte, while other substances (including viruses) were not attached and could, in theory, be separated by washing.<sup>96</sup> The PFC's research had depended on proprietary polyelectrolytes supplied by Monsanto for research purposes only. The company had required that the project should be carried out under strict confidentiality and that all research reports should be destroyed or returned to them. Monsanto were unwilling to agree to license-out the reagent for production purposes, and the project was discontinued.<sup>97</sup>

**20.73** In view of the difficulties encountered, Dr Foster approached research groups, including groups already involved in research collaboration with the SNBTS, at a number of UK universities to encourage them to undertake fundamental research into ways of eliminating the risk of coagulation factor concentrates transmitting hepatitis.<sup>98</sup> However, his attempts to set up collaborations with UK universities were unsuccessful.

**20.74** Until 1981, and the publication of the work of Behring on the pasteurisation of Factor VIII,<sup>99</sup> knowledge of the possibility that Factor VIII might be treated with heat to inactivate virus contamination was limited to those who were aware of the first public disclosure of the work at a symposium in Bonn in October 1980. Professor Cash attended that symposium and reported the information to Dr Foster among others.<sup>100</sup> Dr Foster commented on his response to the information:

I was quite shocked when I heard this claim, as the notion that factor VIII might be able to be heat treated under conditions that would destroy hepatitis viruses was inconceivable to me.<sup>101</sup>

<sup>101</sup> *Ibid* [PEN.012.1438] at 1447–48

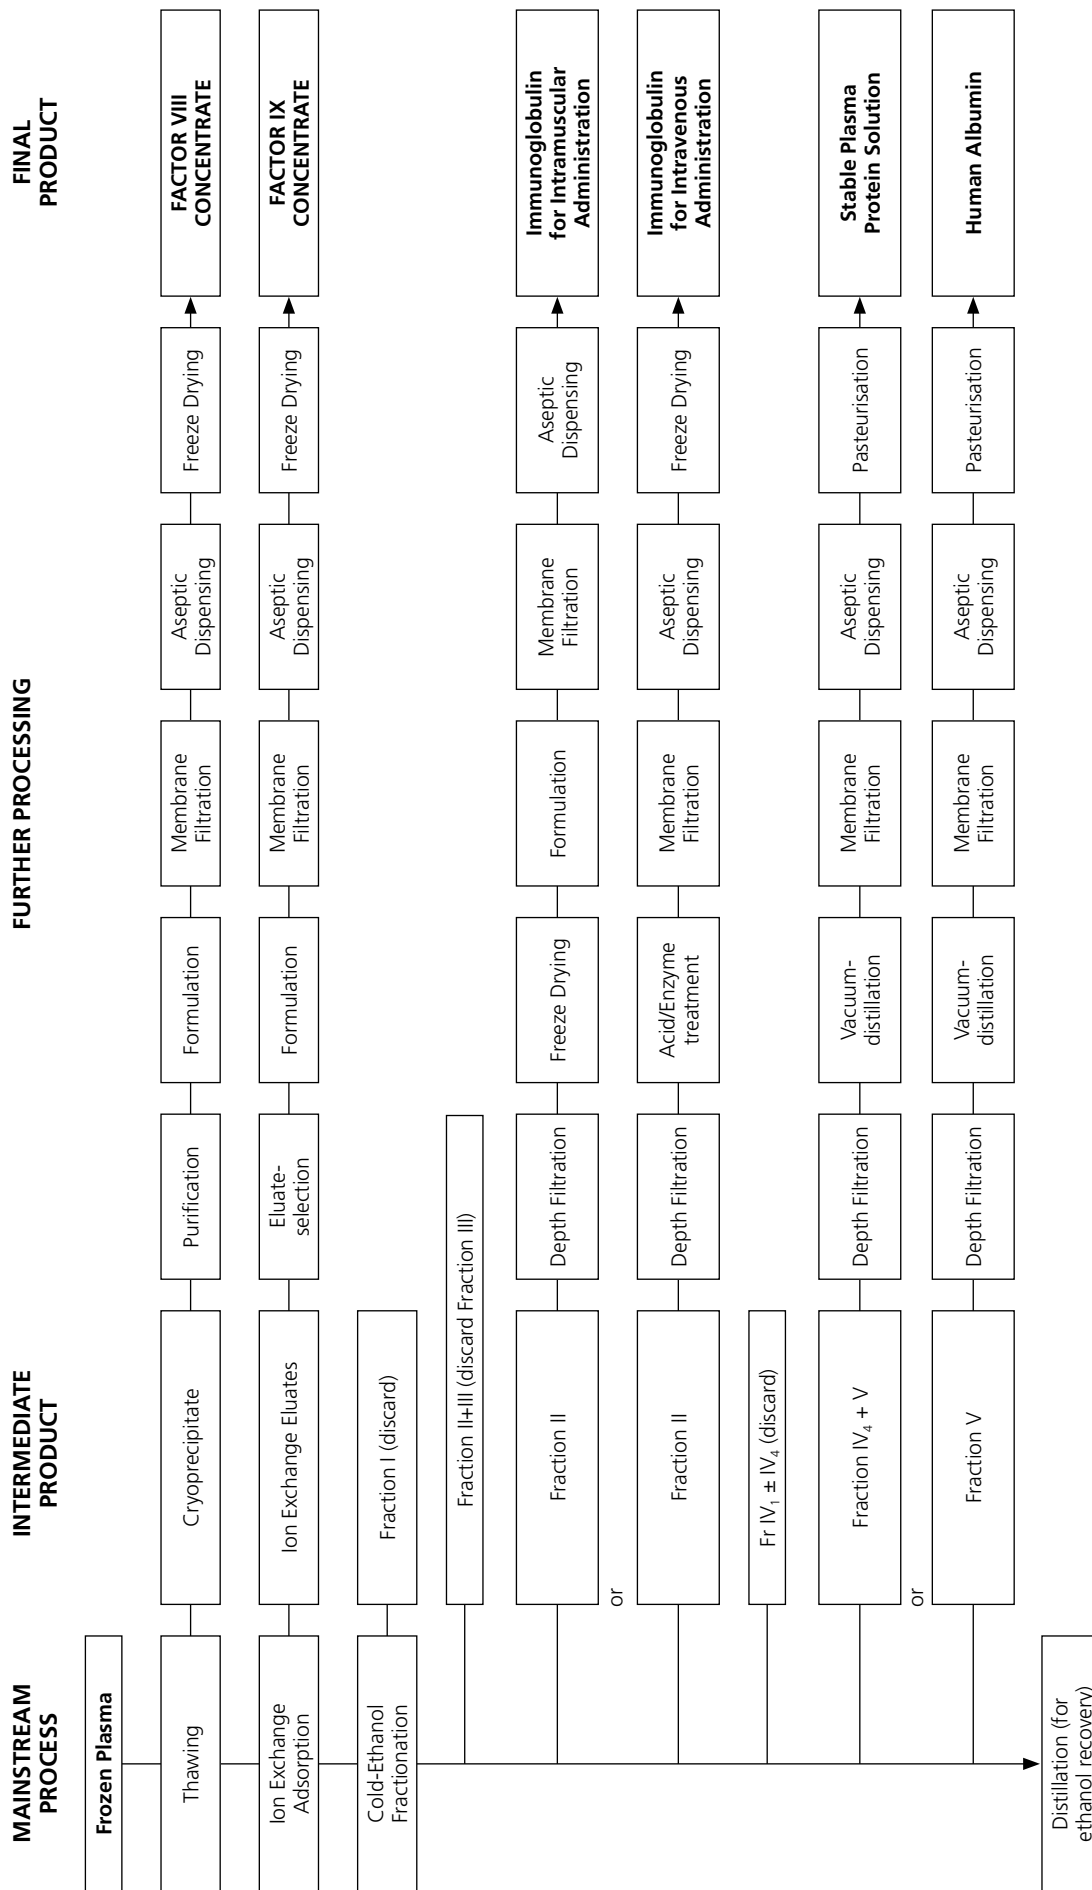

**20.75** Dr Foster had substantial reasons for his reaction. The view of Dr Webb, under whom he had studied at University College London, was that apart from albumin all fractions were heat labile. Dr Foster's own doctoral research made Factor VIII an implausible candidate for research on heat treatment; and experience of the PFC's experiments of filtration performed at 20°C and progressively higher temperatures had confirmed his view that Factor VIII was sensitive to an increase in temperature and that loss of Factor VIII activity was temperature-dependent. The view of others, including Dr Frank Boulton, was that Behring's claims could not possibly be true, and that eventually it would be discovered that it was a mistake.<sup>102</sup>

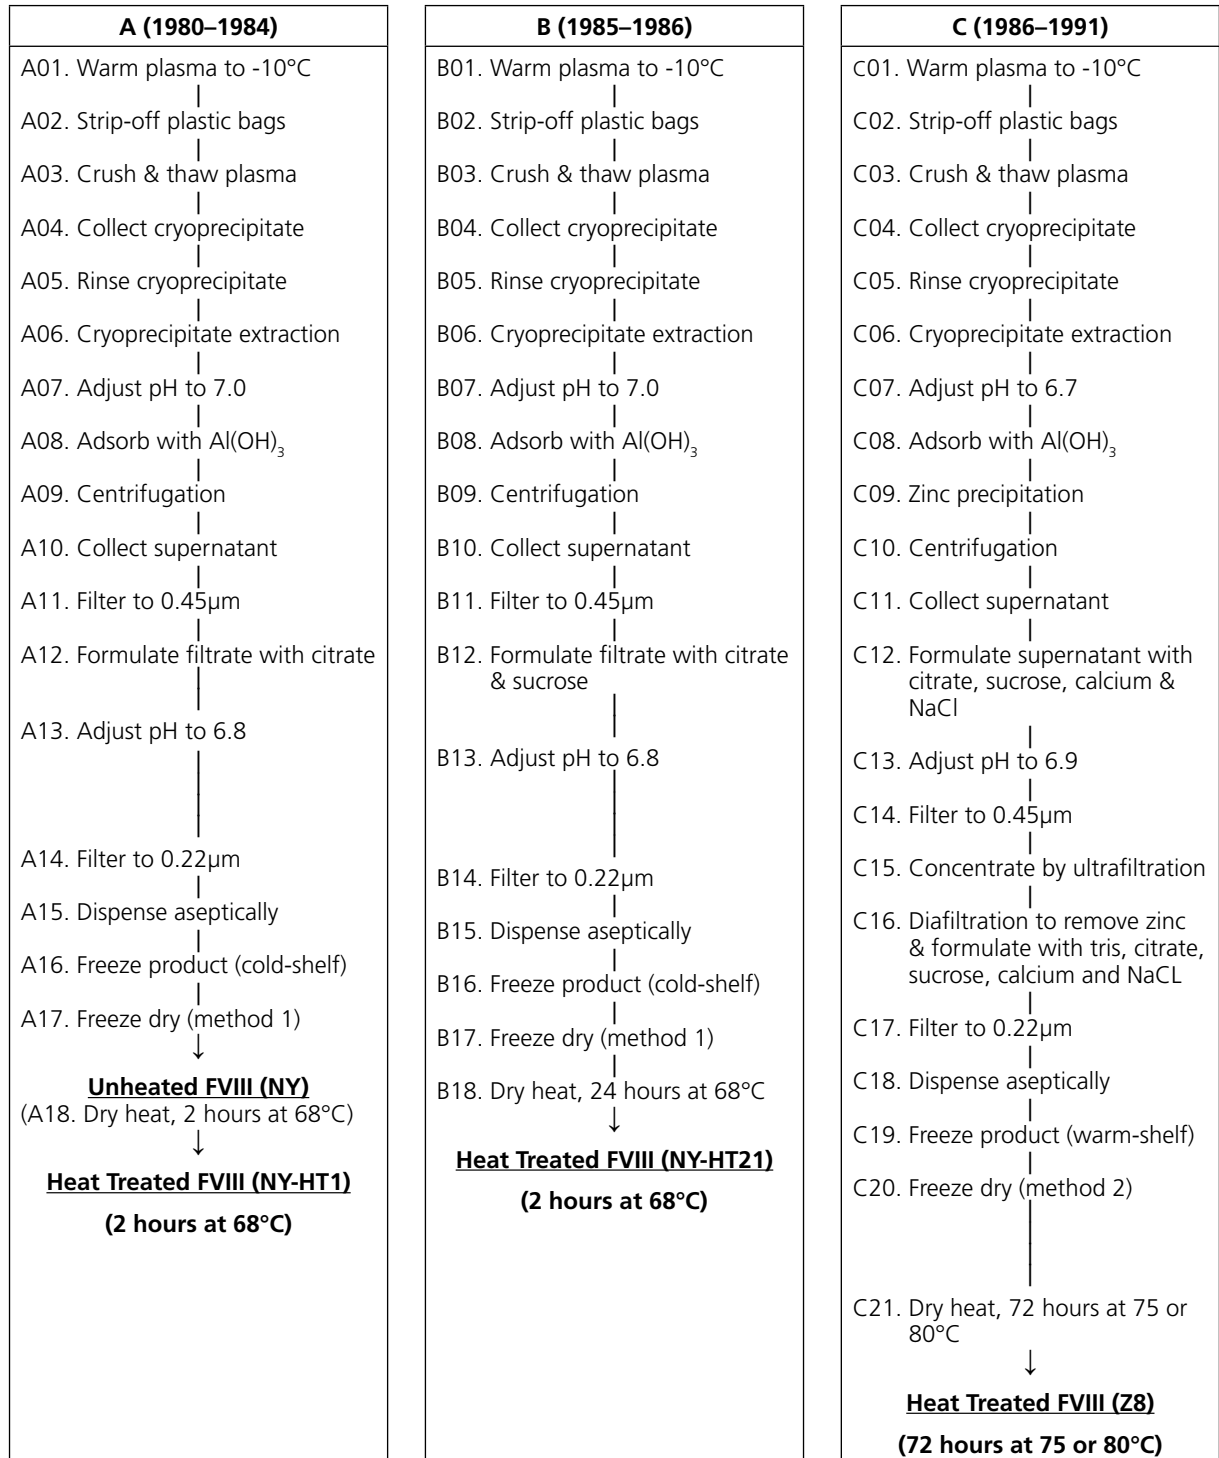

**20.76** On the eve of the outbreak of AIDS, therefore, there was a step change in perception of the possibilities of heat treatment to inactivate hepatitis viruses, but continuing scepticism among scientists. Meantime, research in England, led by Dr John Craske, was reaching the conclusion that all Factor VIII concentrates in production in the early 1980s, imported or NHS, were potentially infective for NANB Hepatitis. The scene was changing rapidly. Viral inactivation by heat treatment is discussed in the following chapters.

# CHAPTER 21

## HAEMOPHILIA THERAPY – USE OF BLOOD PRODUCTS

### Introduction

**21.1** Aspects of two of the Terms of Reference set the general context for discussion of the topics dealt with in this and the 10 chapters:

1. To investigate the systems in place in Scotland for the ... preparation for supply and supply for use by the NHS of blood and blood products with particular reference to the risks of transmission of the Hepatitis C virus ... to patients treated by the NHS in Scotland ....

and

8. To investigate the steps taken by those involved in, and those responsible for, the NHS in Scotland including NHS boards and SNBTS, their officers and employees and associated agencies, to prevent the provision of infected blood and blood products.

**21.2** Reports of AIDS in haemophilia patients treated with blood products, and with no other risk factors for AIDS, brought about a major change in the approach to factor concentrate therapy in the treatment of coagulation disorders in 1983–84. Up to that point, the focus was on the risk of transmission of hepatitis arising from the use of coagulation therapy and on the risk of other adverse effects of therapy such as the development of inhibitors. The history of developing knowledge of hepatitis is discussed in Chapter 14, *Knowledge of Viral Hepatitis 1*, and Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*. It will be appropriate to rehearse some of that history in this chapter to provide context for the decisions taken by haemophilia clinicians in selecting products for therapy.

**21.3** It is necessary to disentangle a number of interrelated strands of history to provide a reasoned response to the Terms of Reference. It is clear, however, that in reality the developing position over this period was 'multifactorial', an expression used frequently in the course of the evidence.

**21.4** The arrival of commercial concentrates in 1973 changed market conditions, and had an impact on the public sector producers in the UK as a whole. Coincidentally, plasma fractionation facilities in Scotland and in England were in the course of or about to undergo major structural changes at the Protein Fractionation Centre (PFC) and the Blood Products Laboratory (BPL) respectively.<sup>1</sup>

**21.5** The first use of commercial concentrates from 1972 coincided with the identification of the Hepatitis B virus (HBV), an agent responsible for blood-borne hepatitis, and development of a test to indicate exposure to HBV by presence in the blood of its surface antigen, subsequently referred to as HBsAg. For a brief period it was hoped that using the HBsAg test to identify all blood donors previously exposed to, and possibly still infected by, HBV would eliminate post-transfusion hepatitis and hepatitis among people with haemophilia. By 1975, studies (mainly in the USA) were indicating that there were one or more other infective agents responsible for a significant proportion of post-transfusion

---

<sup>1</sup> See Chapter 19, *Production of Blood Products – Facilities*

hepatitis, the so-called non-A, non-B Hepatitis (NANBH) virus(es). Producers of Factor VIII products and haemophilia clinicians prescribing their use were faced with a dilemma: whether, on the one hand, to manufacture and use products to relieve real and known risks to the patient and accept the relatively unknown or partially understood risks associated with developing therapy, or, on the other hand, avoid treatment altogether. No form of therapy was without risk to the patient. As commented in Chapter 2, *Patients at Risk*, some risks are inherent in the use of human blood and its components and are always present. Whole blood, fresh and fresh frozen plasma and cryoprecipitate were all associated with risk of transmission of virus infections such as hepatitis.

**21.6** AIDS became the most significant consideration for patients and for medical and scientific staff in the period from about 1982 to about 1985. There are no precise dates that define the period more particularly. After about 1985, transmission of NANBH (later the Hepatitis C virus) and its natural history emerged as the main focal points affecting the management of patients. This chapter will deal with developments before the AIDS period. However, it will be convenient to deal with statistical data for the period to 1991 as a whole.

**21.7** It has been necessary to deal with some aspects of the relevant history separately. The evolution and manufacture of blood products before and during the period was dealt with in Chapter 20, *Haemophilia Therapy – The Period up to the Early 1980s*. This chapter deals with the availability and use of human blood products in haemophilia therapy.

### **Treatment of haemophilia: Overview**

**21.8** Until well into the twentieth century, treatment of haemophilia and other coagulation deficiencies and the complications associated with the diseases was rudimentary. Whole blood or fresh plasma might be transfused in an attempt to replace missing or deficient levels of clotting factors. A major risk associated with those forms of treatment was overload of the recipient's circulatory system which could result in heart failure. From about 1941, human plasma was freeze-dried (lyophilised).<sup>2</sup> The preparation of frozen plasma from whole blood was the first step towards developing therapeutic plasma products. In freeze-dried form, plasma had a substantial shelf-life. It could be stored for up to three months without perceptible change.<sup>3</sup> That removed the need for immediately available supplies of fresh plasma. But it did not solve the problem of circulatory overload.

**21.9** Professor Christopher Ludlam explained the treatments that were available before concentrates were developed.<sup>4</sup> If bleeding into a joint occurred, the patient was advised to take bed rest. He might spend up to several weeks resting until the painful swelling gradually subsided. Fresh frozen plasma was administered on occasion but, because of the risk of overloading the circulation, it was not given in quantities large enough to raise the patient's Factor VIII level sufficiently to stop the bleeding. A bleed was a significant event, often requiring a stay in hospital.

**21.10** A major advance in therapy came in the 1950s with the development of methods of plasma fractionation. This enabled the production of early forms of coagulation factor concentrates. From the 1960s, a simpler process of partitioning of whole blood led to

---

<sup>3</sup> Newman et al, 'Methods for the Production of Clinically Effective Intermediate- and High-Purity Factor VIII Concentrates', *British Journal of Haematology*, 1971; 21:1 [SGF.001.1913]

<sup>4</sup> Professor Ludlam's draft, *Expert Report Human Immunodeficiency Virus Infection in Haemophiliacs*, 1990 [PEN.015.0385]

the production of cryoprecipitate.<sup>5</sup> Subject to availability of supplies, by the very early 1970s, haemophilia clinicians had at their disposal, in addition to fresh frozen plasma, early concentrates of Factor VIII and Factor IX, and cryoprecipitate.

**21.11** As set out in Chapter 19, *Production of Blood Products – Facilities*, there was considerable uncertainty about the levels of demand for haemophilia therapy in the UK as a whole in the late 1960s and early 1970s. That affected the planning of production facilities in England and in Scotland. It also affected perceptions of developments in the market for blood products. When development of the NHS plasma fractionation facilities was planned, there was a poor understanding of the likely drivers of domestic demand for haemophilia therapy. The history of reactive, and often in-patient, treatment of bleeds, with a limited range of therapeutic materials, did not prepare policy-makers or the public sector manufacturers of blood products for changes in clinical practice that generated ever-increasing demand for concentrates, and for improvements in their effectiveness and ease of use.

**21.12** In general terms it was understood that demand would rise. In *Self-Sufficiency in Blood Products in England and Wales: a Chronology from 1973 to 1991*, the Department of Health (DoH) commented:

It became apparent in early 1973 that production of factor VIII concentrate in the UK was insufficient to meet the stated needs of clinicians. There was a body of evidence suggesting that considerably more concentrate would be used if it were available.<sup>6</sup>

However, the general understanding reflected in the statement did not inform planners of the enormous scope for use of coagulation products that was to emerge.

**21.13** As a result, there was a deficiency in planning. It is, however, relevant to note that by 1973 forms of concentrate had been produced in the UK for nearly 20 years, and cryoprecipitate had been readily available for about 15 years. Actual demand for therapeutic materials had been limited by the supplies available. Clinicians could not prescribe what they could not procure, and there was to prove to be very substantial unmet demand. But it had also taken a considerable time for the potential of coagulation products to be understood, and growing knowledge aggravated the problems of supply as clinicians explored treatment options. Furthermore, by no means all patients with haemophilia who might require treatment had been identified by 1973 in the UK.

**21.14** In 1973, Scotland was preparing to move production to a new PFC facility that would change the supply position in this country, but not because of a more accurate assessment of domestic Scottish needs in response to changing demand. In that respect the Scottish position was similar to that in England and Wales ('UK' in DoH terms): the potential demand was underestimated. Commercial pharmaceutical companies had already identified the market for increased supplies of concentrates. On 3 December 1972 Baxter applied for a UK licence for Hemofil, which was granted on 19 February 1973. On 8 December Immuno applied for a UK licence for Kryobulin, which was granted on 22 March 1973.<sup>7</sup> Early release of their products stimulated demand.

<sup>5</sup> See Chapter 20, *Haemophilia Therapy – The Period up to the Early 1980s*, paragraphs 20.21–20.24

### Treatment policy in England and Wales: The early 1970s

**21.15** During 1972, the majority of Haemophilia Centre Directors in England and Wales had expressed a preference for freeze-dried concentrate therapy.<sup>8</sup> Dr Brian Colvin said that he and his colleagues at the London Hospital began to use them in 1970.<sup>9</sup> It seems likely that, at such an early date, the materials would have been used in clinical trials. Commercial products were more generally available and in use on a named patient basis in 1972.

**21.16** On 6 March 1973 a letter was sent by the Chief Medical Officer (CMO) for England and Wales to all senior administrative medical officers (SAMOs) advising them that two product licences referred to had recently been granted to Baxter and Immuno which enabled the licensees to supply foreign human Anti-haemophiliac Globulin (AHG) concentrate to hospitals and haemophilia centres in the UK. Hemofil and Kryobulin could now be prescribed as licensed products.<sup>10</sup> The CMO noted that AHG concentrate was in many instances the therapeutic agent of choice in the treatment of haemophilia patients, and that at the time production of concentrate in the UK was insufficient to meet the stated needs of clinicians who cared for patients requiring surgical, including dental, treatment or who had episodes of severe bleeding. The letter noted that one of the two firms had indicated that it could supply large quantities of AHG. The dynamics of the market place were obvious: if the UK (and more specifically England and Wales) had the demand, the pharmaceutical companies could supply it.

**21.17** But there were serious concerns about the very high cost of the foreign AHG. An expert group was set up by the Medical Division of the Department of Health to assess need and arrangements for the purchase of the product and also the possibility of producing sufficient material in the UK, and to advise the Department.<sup>11</sup> The expert group included representatives from Scotland, and policy recommendations reflected the view held at that time that it was essential that the production and distribution of the therapeutic agents for haemophilia care should be considered as a UK exercise. However, the data on demand and supply discussed by the group related mainly to England and Wales.

**21.18** So far as they related to planning of domestic production, the expert group's views are discussed in Chapter 19, *Production of Blood Products – Facilities*.<sup>12</sup> It was recognised by the group that the number of registered patients with haemophilia underestimated the scale of demand.<sup>13</sup> It was thought that 3000 was a reasonable estimate of the number of individuals affected with haemophilia. The discussion covered the grounds for preference of cryoprecipitate and freeze-dried concentrate over other products and their relative advantages and disadvantages.

**21.19** The reported discussion of the group provides insight into the view of risk associated with therapeutic products that was prevalent at the time. As a practical matter, transmission of Hepatitis B was the central issue.

The present policy of rejecting donations which give a positive test for hepatitis B antigen will reduce the incidence of virus in the blood used to make plasma pools. In practice, studies in several centres have shown that the incidence of

<sup>12</sup> Paragraphs 19.26–19.30

<sup>13</sup> Note of meeting of Expert Group on the Treatment of Haemophilia, 20 March 1973 [SNB.006.7631]

hepatitis among severely affected patients who have been treated with the freeze-dried preparation is not very much higher than that at centres not using freeze-dried concentrate and this suggests that the development of hepatitis in these multitransfused patients may be dose-related. It was agreed that the theoretically increased risk of acquiring hepatitis (which does not seem to be borne out in practice) should not be a deterrent to using the freeze-dried preparation and in any case this complication will decrease with universal screening of donors for hepatitis antigen.<sup>14</sup>

It was agreed within the group that products from 400,000 donations would be required to treat UK sufferers from haemophilia of all degrees of severity. More would be required if strenuous efforts were made to clear surgical waiting lists and if home treatment, or eventually prophylactic treatment, became accepted ways of dealing with the needs of haemophilia patients. Demand exceeded NHS production capacity, but it was agreed that:

Since more freeze-dried AHG concentrate has become available from two foreign sources the prospects of improved management of day-to-day bleeding episodes using this therapeutic agent has become realistic.<sup>15</sup>

**21.20** It was accepted at that stage, as a reality, that the NHS production facilities in England could not cope with the anticipated demand and that commercial purchases would be necessary. NHS concentrate from 30,000 blood donations had been issued in England, Wales and Northern Ireland in 1972, as against the estimated future requirement of 400,000 donations.

**21.21** Recommendations of the group included:

- DHSS should give early consideration to central purchase of freeze-dried AHG concentrate from the firms who had recently been granted product licences.
- Distribution to haemophilia centres and hospitals in Scotland should be through the regional centres (either Edinburgh or Glasgow).
- Discussions were to take place between DHSS and the Regional Transfusion Directors about the problems of decreasing production of cryoprecipitate, increasing production of fresh-frozen plasma for fractionation and the possibility of increased collection of plasma by plasmapheresis.
- Home treatment and, in due course, prophylactic treatment were subjects that needed to be discussed further at future meetings.

**21.22** These recommendations, concentrating on practical implementation of policy, reflect the group's assessment of related risk. The general understanding of risk is discussed in Chapter 14, *Knowledge of Viral Hepatitis 1*. When the expert group met in 1973 the Maycock report for the MRC had not been published,<sup>16</sup> but when it did appear in 1974 the Maycock report would underestimate the true incidence of post-transfusion hepatitis, largely because of the requirements stipulated for a diagnosis of the disease.<sup>17</sup> Dr William

<sup>14</sup> Ibid [SNB.006.7631] at 7633

<sup>15</sup> Ibid

<sup>16</sup> Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraph 14.20

<sup>17</sup> Ibid paragraph 14.22

Maycock was a member of the expert group, and knowledge of the report's findings can reasonably be assumed. At this stage it is sufficient to note that the expert group's discussions in 1973 did not reflect any perception that there was a relatively high risk of transmission of infection associated with commercial products, or that such increased risk as was recognised was significant.

### **Self-sufficiency**

**21.23** During the early and mid-1970s there was emphasis in UK Government policy on achieving self-sufficiency in blood and blood products, reflecting views expressed by the World Health Organization (WHO). The reasons advanced for self-sufficiency are again significant.

**21.24** In May 1975, a WHO resolution was passed by delegates conscious of the increasing use of blood and blood products. It urged Member States:

- To promote the development of national blood services based on voluntary non-remunerated donation of blood.
- To enact effective legislation governing the operation of blood services and to take other actions necessary to protect and promote the health of blood donors and of recipients of blood and blood products.

**21.25** In making its recommendations the WHO had considered:

[T]he extensive and increasing activities of private firms in trying to establish commercial blood collection and plasmapheresis projects in developing countries.

[C]oncern that such activities might interfere with efforts to establish efficient national blood transfusion services based on voluntary non remunerated donations.

[A]wareness of the higher risk of transmitting diseases when blood products have been obtained from paid rather than voluntary donors, and of the harmful consequences to the health of donors of too frequent blood donations (one of the causes being remuneration) ....<sup>18</sup>

Relative risk had been identified as an issue, focused on the dangers associated with paid donors.

**21.26** On 24 December 1974 the DHSS wrote to all regional administrators about the problems of blood product production and in particular the inability of the Blood Transfusion Service to meet the demands of clinicians for certain preparations of human blood. There was an immediate need to provide more AHG (Factor VIII) concentrate. The memorandum stated:

At present part of the demand ... is being met by expensive imported material which is now marketed in this country, and as the demand increases commercial firms may consider it worth their while to establish panels of paid donors in this country in order to obtain their supplies of human blood. Such

---

<sup>18</sup> WHO, World Health Assembly Resolution 28.72 of May 1975: *Utilization and Supply of Human Blood & Blood Products* [DHF.003.0764]

a development would constitute a most serious threat to the voluntary donor system upon which the NBTS is founded. The Department therefore regards it as of the greatest importance, quite apart from the question of cost, that the NHS should become self-sufficient as soon as practicable in the production of PPF [plasma protein fraction] and other blood products ....<sup>19</sup>

**21.27** There was a proposal to invite estimates of requirements in regional transfusion centres for the increased production of plasma, with the primary aim of making the NHS self-sufficient in AHG concentrate in two to three years.<sup>20</sup> The concern expressed in the circular letter reflected the second WHO point in paragraph 21.25: it did not express concern about relative infectivity.

**21.28** On one level that is hardly surprising. Following the CMO letters of March 1973, the DHSS had notified relevant parties in England and Wales in October 1973 that the supply division of DHSS had negotiated with Travenol Laboratories Ltd and Serological Products Ltd to enable haemophilia centres to purchase AHG concentrate.<sup>21</sup> This letter advised parties that the department was in close cooperation with the SHHD in considering ways of increasing NHS production. In November 1973 a circular letter was sent to Scottish administrative medical officers in very similar terms.<sup>22</sup> Adverse comment on commercial products generally would have been inconsistent with this approach to meeting need, and comment on specific products would have offered a hostage to fortune. But, perhaps more pertinent to this discussion, it reflected a common understanding in government that distinctions related to transmission of infection were not significant.

**21.29** In January and February 1975 Dr David Owen told the House of Commons that the amount of Factor VIII materials, including cryoprecipitate, produced within the NHS was not sufficient to meet demand at that time. In particular, there was an immediate need for AHG concentrate (acknowledged as the preferred treatment for haemophilia). Dr Owen stressed that it was of vital importance that the NHS should become self-sufficient as soon as practicable in the production of Factor VIII, including AHG concentrate. He announced that special finance of up to £500,000 had been allocated with the objective of the NHS becoming self-sufficient over the next few years, and expected that this would stop the dependence on commercial imports and make the best known treatment more readily available to people suffering from haemophilia.<sup>23</sup> There was no separate policy statement relating to self-sufficiency in Scotland at this time.<sup>24</sup> There was awareness in Scotland among all those working in the field that self-sufficiency was what was being sought: Dr Robert Perry referred to self-sufficiency as 'the only game in town'.<sup>25</sup>

**21.30** However, across the UK as a whole, the reality of burgeoning demand for Factor VIII replacement therapy posed a serious challenge to the government's commitment to self-sufficiency. Data are available for the amounts of Factor VIII concentrates used in the whole of the UK. Equivalent information is not available for the use of Factor IX or cryoprecipitate, both of which were largely produced locally and met local demand for NHS products. The discussion which follows does not present a comprehensive picture of

<sup>25</sup> Dr Perry – Day 25, page 5

total haemophilia, but it was the demand for Factor VIII that was the critical consideration in aiming at self-sufficiency.

**21.31** Total annual consumption of Factor VIII concentrates in the UK between 1970 and 1990 is shown in Figure 21.1. The data are set out in Table 21.1 in the Appendix to this chapter.

**Figure 21.1: Total annual consumption of Factor VIII concentrates in the UK, 1970–1990**

**21.32** These data for the UK as a whole show sustained growth in use of Factor VIII concentrates from 1975 onwards, with a dip in 1983 that was reversed thereafter. The dip in 1983 probably related to the switch to cryoprecipitate in response to the threat of AIDS.

**21.33** The trend shown in Figure 21.1 suggests planning for the provision of NHS Factor VIII based on experience up to the mid-1970s was unlikely to be remotely accurate. It would have required a high degree of imaginative foresight rather than statistical projection to forecast and provide for demand.

**21.34** Although all parts of the UK were subject to the same growing demand throughout this period, the circumstances in which the different parts of the UK found themselves towards the end of the 1970s led to the demand for Factor VIII concentrates being met in different ways.

**21.35** As events happened, and despite WHO encouragement, the target of self-sufficiency in England, Wales and Northern Ireland was most unlikely to have been achieved with the level of expenditure granted by Parliament while demand was left free to grow without restriction.

**21.36** Figure 21.2 shows, for England, Wales and Northern Ireland, the annual consumption of NHS and imported commercial Factor VIII concentrates between 1970 and 1990. The data are set out in Table 21.1 in the Appendix to this Chapter.

**Figure 21.2: Annual consumption of NHS and commercial Factor VIII concentrates in the UK, excluding Scotland, 1970–1990**

**21.37** Figure 21.2 illustrates the extent of the use by clinicians of imported commercial Factor VIII concentrate and, in respect of that product, shows the deficiencies in domestic supplies. The source data do not distinguish use related to clinical preference from use dictated by available supplies. Total use of commercial products cannot be explained exclusively on the basis of clinical choice in the circumstances, but it may have been a contributory factor. Subject to that, the overall impression is of rapidly increasing demand for Factor VIII concentrate, met substantially by imported product.

**21.38** Figure 21.3 shows, for the UK excluding Scotland, the percentage of total Factor VIII concentrate consumption from NHS and from commercial supplies in each year from 1970 to 1990. The data are contained in Table 21.1 in the Appendix to this chapter.

**Figure 21.3: Percentage of total Factor VIII concentrate consumption from NHS and commercial sources for the UK, excluding Scotland, 1970–1990**

**21.39** On the evidence before the Inquiry, there was some scepticism whether self-sufficiency was possible. In relation to England and Wales, Professor Cash said that he did not consider self-sufficiency was a realistic goal as there were insufficient resources. In his opinion, Scotland was already ahead of England and Wales in the mid-1970s in achieving this aim.<sup>26</sup>

**21.40** Professor Cash described the reaction to a talk he gave on the notion of self-sufficiency at a World Federation of Hemophilia congress in New York in 1977. His talk was interrupted by the then Chief Executive of Immuno, Dr Eibl, who, as Professor Cash recalled it, told the audience that he, John Cash, was talking nonsense and that the UK government did not accept that the WHO commitment to self-sufficiency was achievable. A member of the UK Haemophilia Society who was present, told Professor Cash that the Society agreed with Dr Eibl. Moreover, the Society did not think that the NHS would get anywhere near self-sufficiency in England and Wales.<sup>27</sup> Professor Cash thought that, despite the talk in England and Wales about self-sufficiency, 'they just weren't in the hunt' and had been told so.

**21.41** It is unnecessary, and would be inappropriate, to express any view on these observations. The steep increase in demand from 1975 would have challenged the ability of policy-makers to respond. Comparison with Scotland (so far as concerns the capacity to respond to increasing demand) is particularly inappropriate. It is necessary to bear in mind that, as discussed in Chapter 19, *Production of Blood Products – Facilities*, Scotland's favourable position in relation to meeting growing demand was due to the government providing resources to build a new centre – the PFC – at which it was originally aimed to process about a third of English plasma in addition to all Scottish plasma. Making use of

<sup>26</sup> Professor Cash – Day 25, pages 83–85

<sup>27</sup> Ibid pages 87–88

the Scottish facility for processing output of plasma produced in England and Wales was proposed in the Department of Health's letter to regional administrators on 24 December 1974, for example.<sup>28</sup> The failure to achieve a practical means of realising that policy objective made a significant contribution to Scotland's relative lack of dependence on imports, and aggravated the problem in the rest of the UK, in the 1980s.

### **Demand and supply in Scotland**

**21.42** In Scotland, as in the rest of the UK, there was interest in the impending arrival of commercial concentrates in the early 1970s. A Working Party was set up by the Central Consultative Committee on Blood Transfusion (CCC): 'To consider the production, laboratory and clinical evaluation of the various factor VIII and IX products in relation to the overall production capacity of the Blood Transfusion Service and to report.'<sup>29</sup> The group met on 21 September 1972 and the minutes of the meeting were circulated for discussion. It was estimated that 30,000 donations a year would be required for the production of Factor VIII concentrate.

**21.43** It was recorded that consideration must be given to how much Factor VIII should be provided in the form of cryoglobulin precipitate (cryoprecipitate) and how much in the form of an AHF (Factor VIII) concentrate prepared by the fractionation unit (then still a small-scale operation at the Royal Infirmary of Edinburgh (RIE)). The recent appearance of commercially prepared concentrate was also discussed, although licences had not been granted at that point. It was agreed that treatment in the form of cryoprecipitate would continue for most patients for the foreseeable future but the desire was to replace this treatment and Cohn Fraction I with a potent AHF concentrate. Such a concentrate was liable to be subjected to more rigorous quality control. However it was conceded that estimating demand for a new product was difficult and was on a 'guess at best' basis.

**21.44** Availability of a 'super-concentrate' (the commercial concentrate) was discussed in Scotland when the CCC itself met on 15 March 1973.<sup>30</sup> The general feeling was that Scotland should be able to manufacture enough of its own product from Scottish blood donations and would only require commercial material in very small quantities. By this time the estimated requirement of 30,000 donations a year for production of Factor VIII concentrate for Scottish patients was thought likely to be an underestimate, and the more realistic figure would be 50,000 donations.<sup>31</sup>

**21.45** On 28 March 1973, the SHHD issued a letter to the SAMOs (copied to the Directors of Haemophilia Centres, Regional Directors of the Blood Transfusion Service (BTS) and the Scientific Director of PFC) on 'Trends in the Treatment of Haemophilia', in terms almost identical to the English CMO letter of 6 March 1973.<sup>32</sup>

**21.46** Total annual consumption of Factor VIII concentrates in Scotland between 1970 and 1990 is shown in Figure 21.4. The data are set out in Table 21.1 in the Appendix to this chapter.

<sup>28</sup> DHSS letter of 24 December 1974 to Regional Administrators [DHF.002.9393] at 9393–94

**Figure 21.4: Annual consumption of Factor VIII concentrates in Scotland, 1970–1990**

**21.47** Information provided to the Inquiry by the United Kingdom Haemophilia Centre Doctors' Organisation (UKHCDO) for this period is not complete.<sup>33</sup> There are gaps in some early years which affect the reliability of the data until the mid-1970s. But the trend in consumption of Factor VIII concentrates is sufficiently well defined for comparison with the rest of the UK.

**21.48** As in the rest of the UK, the data show sustained growth in use of Factor VIII concentrates from about 1975 onwards. Figure 21.4 shows a significant spike in consumption in 1988. This is accounted for by a major rise in demand at the Royal Hospital for Sick Children (Yorkhill) in Glasgow, and is discussed further at paragraph 21.292 below.

**21.49** There is no obvious explanation for the dip in consumption of Factor VIII concentrates in 1985 and 1986. It cannot be related to a switch to cryoprecipitate in response to the threat of AIDS, as was the position in 1983 in the rest of the UK. Effective viral inactivation had been introduced at the beginning of 1985. Nor do SNBTS figures for the amount of frozen plasma collected through this period suggest any supply constraints.<sup>34</sup>

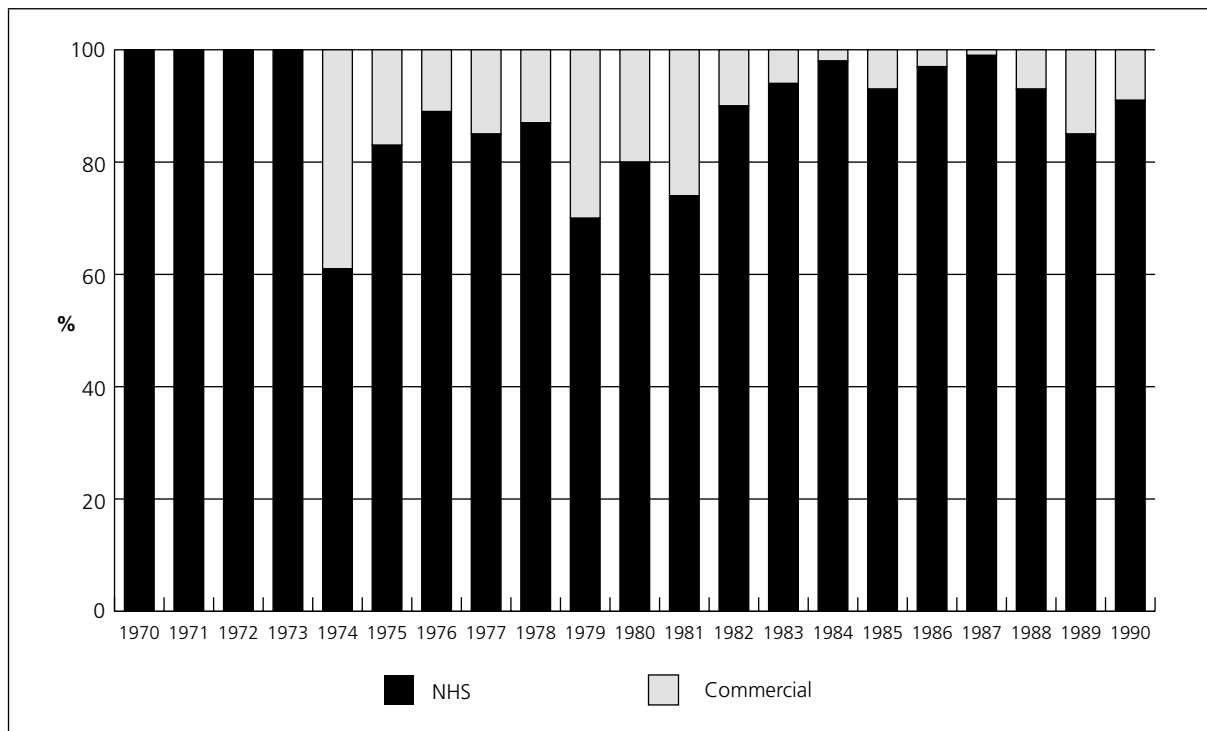

**21.50** Scotland, in common with the UK as a whole, experienced a rise in demand for Factor VIII concentrates from the beginning of the Inquiry's reference period until the late 1980s that was far in excess of what those involved in planning at the beginning of the 1970s could have expected. The inability of NHS sources to supply demand inevitably led to the importation of commercially prepared products from North America from 1972. Nevertheless, in comparison with the rest of the UK, Scottish production met a substantial proportion of the demand for Factor VIII concentrates.

<sup>33</sup> *National Haemophilia Database: Bleeding disorder statistics for the Penrose Inquiry*, UKHCDO, April 2012 [PEN.019.0927] at 0933-34

<sup>34</sup> SNBTS paper, *Self-Sufficiency and the Supply of Blood Products in Scotland*, February 2011 [PEN.013.1125] at 1158–59

**21.51** Figure 21.5 shows the percentage of total Scottish Factor VIII concentrate consumption met from NHS and from commercial supplies in each year from 1970 to 1990. The data are contained in Table 21.1 in the Appendix to this chapter.

**Figure 21.5: Percentage of Scottish Factor VIII concentrate consumption from commercial and NHS sources, 1970–1990**

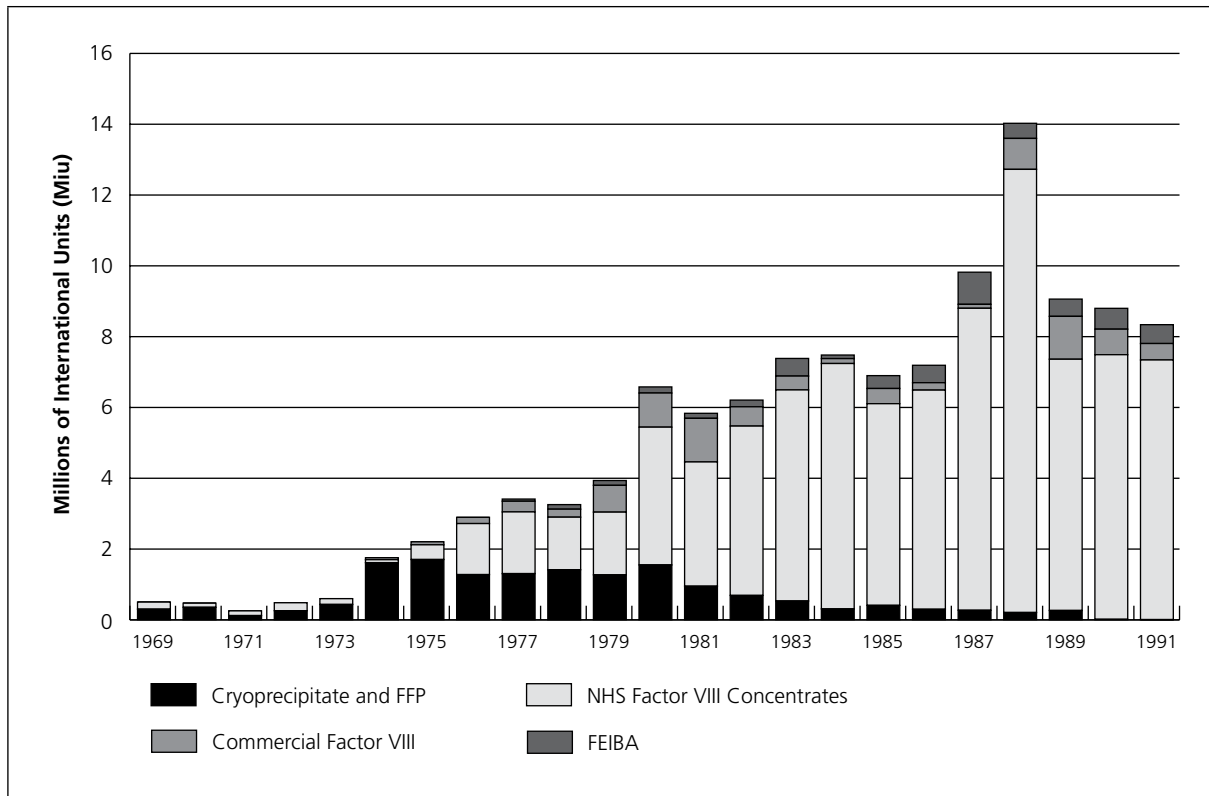

**21.52** As is apparent from Figure 21.5, total use of NHS concentrates far exceeded use of commercial Factor VIII products throughout the period, even in 1974 when the PFC's production was disrupted by the move to Liberton. In Figure 21.5, NHS data include some material sourced from the BPL for Scottish use. But the amounts were relatively small, in total, and do not materially affect the position. As already indicated in paragraph 21.41, production facilities in Scotland had considerably more capacity relative to total domestic demand than was available in England and Wales.

### Choice of therapeutic products

**21.53** The comparative exercise discussed above, as between Scotland on the one hand and the rest of the UK on the other, does not take account of all therapeutic materials used for Haemophilia A therapy over the period 1969–91, and it is necessary to turn to that topic at this stage in order to describe fully what happened in Scotland. As already indicated, for all of the period there was some use of cryoprecipitate, very small amounts of fresh frozen plasma, and FEIBA in addition to Factor VIII concentrates. Cryoprecipitate and fresh frozen plasma were prepared from single donations (though usually administered in pools or in succession in larger numbers) and, for present purposes, can conveniently be grouped. FEIBA was not used exclusively in treatment of patients with Haemophilia A, but had a significant place in the treatment of Factor VIII deficient patients with inhibitors. There are no data to enable the allocation of total FEIBA between Haemophilia A, Haemophilia B and other blood coagulation disorders. From 1979 onwards there was some limited use of DDAVP, but the quantities were insignificant in relation to total use and have not been noted at this stage.

**21.54** Figure 21.6 shows the use of Factor VIII replacement products in Scotland between 1969 and 1991. The data are set out in Table 21.2 of the Appendix to this chapter.

**Figure 21.6: Scottish use of Factor VIII replacement products in Millions of International Units (Miu) – 1969–1991**

**21.55** As noted above, some caution must be used when looking at the data for the early part of the period. At that time, cryoprecipitate and fresh frozen plasma were the principal therapeutic products in use. NHS Factor VIII concentrate then grew in significance, and remained the principal product in use throughout the period. Commercial Factor VIII concentrate remained a small proportion of the total, as did FEIBA.

**21.56** In practice, individual haemophilia clinicians exercised a degree of autonomy in the selection and prescription of products, if they had independent funds or if the relevant health authority supported the choice. Within Scotland there were significant variations between regions, which will be discussed later in this chapter. There were, however, a number of general factors that had an influence on product choice.

**21.57** The PFC's move to Liberton interrupted production in the early part of this period. Bulk stocks of intermediate Factor VIII were prepared at the RIE to carry over the transitional period. In addition, to effect a smooth changeover from cryoprecipitate to intermediate Factor VIII in the treatment of haemophilia an initial stockpile of about one million units was required, and stocks were built up in anticipation of that change.<sup>35</sup>

**21.58** Two observations are appropriate. First, the total issues of Factor VIII concentrates before the PFC was commissioned were relatively small: there was not much AHG available for issue to regions until the PFC was fully in operation, when there was a rapid build-up

<sup>35</sup> Minutes of SNBTS Directors Meeting, 15 October 1974 [SNB.002.4952]

of output. Secondly, although there was a major increase in use of cryoprecipitate and fresh frozen plasma in 1974 and 1975, coinciding with the transitional period at the PFC, use of cryoprecipitate continued to be significant for the rest of the decade until falling away after 1980.

**21.59** Some clinicians, however, were beginning to express views, as early as 1974, on the future availability of products to meet changes in clinical practice. On 18 December 1974, Dr Howard Davies, then Director of the haemophilia centre of the RIE wrote to Professor Cash (copying in John Watt of the PFC) stating that he hoped that sufficient supplies of human intermediate Factor VIII concentrate would be available in Edinburgh in January 1975 to cover the operative needs of his haemophilia patients and enable him to start some of them on home therapy.<sup>36</sup> In response, John Watt sent a telex to Professor Cash on 23 December 1974 suggesting that Dr Davies needed to be a little patient a little longer. He explained that production of Interate<sup>37</sup> had not yet started and he envisaged that volume problems would continue until supplies of fresh frozen plasma increased to a reasonably stable figure above 500 donations per week. He estimated that regular output would not be available until April.<sup>38</sup> However, timetable apart, it appears clear that clinicians' choice of product would become a more significant issue once the PFC was in full production.

**21.60** Scottish clinical practice was entering a period when clinicians' choice would be made against a background of more ample supplies of therapeutic products than had previously been available. Already, however, Dr Davies had pointed to two aspects of practice that were to increase pressure on supplies: elective surgery and the move to home treatment.

**21.61** Whether Scotland achieved self-sufficiency in the events that happened is, to some extent, dependent on the definition of demand. In an environment in which individual clinicians were free to select commercial products, given appropriate funding by local health authorities, by industry or by charities, actual demand for NHS products cannot be a reliable measure of total demand. Where available supplies are known to be limited, clinicians may have accepted the reality and avoided making demands on the NHS facilities that could not be met. Dr Peter Foster commented:

I think if you go back into the 1970s, when PFC was really still getting going and usually doctors were moving forward with home therapy, there is clearly correspondence where SNBTS is really saying, 'Look, we can't provide more at the moment, and the choice is for you', and they decide to buy commercial product because they want to do home therapy. So there is a period when clearly there is a discontinuity between the aspirations of the clinicians and what we can provide.<sup>39</sup>

**21.62** In the mid-1970s the Scottish internal market had not settled, and choice may not have been real. However, Dr Foster prepared a report on 'Self Sufficiency and the Supply of Blood Products in Scotland', with particular reference to the treatment of Haemophilia A which is helpful.<sup>40</sup> He tabulated the amounts of Factor VIII available from the SNBTS

<sup>36</sup> Dr Davies' letter of 18 December 1974 to Dr Cash [SNB.007.2254]

<sup>37</sup> Interate was the new PFC Factor VIII product.

<sup>38</sup> Mr Watt's telex of 23 December 1974 to Dr Cash [SNB.007.2255]

<sup>39</sup> Dr Foster – Day 22, pages 129–130

<sup>40</sup> SNBTS paper, *Self-Sufficiency and the Supply of Blood Products in Scotland*, February 2011 [PEN.013.1125]

compared with the amounts used clinically (as understood from UKHCDO data available before revision for the purposes of the Inquiry) in the period 1975–88. The data, expressed in terms of million units per head of population at each year, are reproduced below.<sup>41</sup>

Year	Total SNBTS FVIII Available (Miu per pop.)		Proportion of Clinical Use Matched by Available FVIII from SNBTS (% average UK use per pop.)	
	Incl. Cryo	Excl. Cryo	Incl. Cryo	Excl. Cryo
1975/76	0.97	0.21	202	111
1976/77	0.86	0.33	134	103
1977/78	0.99	0.39	129	100
1978/79	1.11	0.44	134	70
1979/80	1.27	0.69	136	89
1980/81	1.49	0.99	141	109
1981/82	1.48	1.14	123	105
1982/83	1.80	1.55	138	129
1983/84	1.94	1.71	149	142
1984/85	2.85	2.60	204	197
1985/86	2.56	2.23	180	163
1986/87	2.75	2.50	177	166
1987/88	2.20	1.93	138	125

**21.63** Dr Foster’s data and the UKHCDO data were prepared on different bases, with reference to overlapping periods: they cannot be correlated precisely. However presented, the data paint a very different picture from that shown for England, Wales and Northern Ireland so far as concerns the balance between use of NHS product and commercial product. It is necessary to bear this in mind when considering comments on the supply position in the ‘United Kingdom’, particularly in documents recovered from UK departments. Throughout the UK (including Scotland), however, there was a similar increase in demand overall. In the early 1980s, annual consumption of Factor VIII concentrate in Scotland, as registered by the UKHCDO, more than doubled in comparison with the late 1970s.

**21.64** In relation to his data, Dr Foster concluded:

The data in Table 18 [reproduced at paragraph 21.62 above] indicate that at any point in time the SNBTS had available sufficient Factor VIII to meet average UK clinical practice, if cryoprecipitate was considered to be suitable to supplement Factor VIII concentrate. If cryoprecipitate is excluded then, with exception of the two year period 1978/9 – 1979/80, the availability of Factor VIII concentrate from the SNBTS was sufficient to meet average UK clinical use throughout this period.<sup>42</sup>

**21.65** It was suggested to Dr Foster that the figures in his table for the years 1978–79 and 1979–80 indicated that clinical demand was ahead of the Factor VIII concentrate available from the SNBTS at that time. Figures for the following years did not indicate difficulties

<sup>41</sup> Ibid [PEN.013.1125] at 1184. The expression of production and use data in terms of units per head of population was common at this period. In this table the unit of measurement of available supply is relevant only to the comparison with demand for coagulation therapy, expressed on a consistent basis. The final two columns show the percentage relationship of available SNBTS supplies to average demand, as assessed on a UK basis.

<sup>42</sup> SNBTS paper, *Self-Sufficiency and the Supply of Blood Products in Scotland*, February 2011 [PEN.013.1125] at 1184

of supply. Dr Foster agreed, and said that they were quite clear that they were not able to produce enough concentrate. He told the Inquiry: 'We couldn't meet the aspirations and we were always chasing this moving target'.<sup>43</sup> Dr Foster's assessment of the practical position is accepted: however one presents the available data, he was intimately involved in the production process, and his opinion is reliable.

**21.66** However, it does not present the whole picture. There remains the necessary caveat in relation to any assessment of the balance of supply and demand for products: individual choice was an aspect of practice, and would have differed not only within Scotland but as between Scottish centres and centres in England and Wales. Averaging of UK demand patterns necessarily concealed such differences. 'Self-sufficiency' might imply a capacity to satisfy the demand for NHS products as distinct from the total demand for concentrates where there was a preference for the commercial product that existed independently of whether NHS products were available.

**21.67** It was the view of some witnesses, for example Dr Frank Boulton, that Scotland had become largely self-sufficient by the early 1980s notwithstanding that some commercial product was still being used in Edinburgh and possibly more so in Glasgow.<sup>44</sup> However, Dr Boulton thought that, without there being an actual ban on importation of commercial material, self-sufficiency was a lovely ideal and one to which transfusion services should aspire at all times, but that 'absolute' self-sufficiency was not achievable. There would always be special needs that could not be serviced from local materials.<sup>45</sup> It became a matter of definition. For him, the expression 'absolute self-sufficiency' meant that the community would be able to supply every single vestige of blood or blood products from within that community, with no dependence on outside agencies at all. A more realistic definition, short of perfection, would be that the NHS could service with local products that part of total demand for which clinicians sought NHS products, subject to such regulatory constraints on freedom of prescription as might be in force.

### **Increasing demand for Factor VIII products**

**21.68** At the beginning of the reference period two closely related matters drove increasing demand: the inherent attractiveness of Factor VIII concentrates in haemophilia therapy generally, and, shortly thereafter, a change in clinical practice towards home therapy. As discussed in Chapter 14, *Knowledge of Viral Hepatitis 1*, the late 1960s and early 1970s saw increasing emphasis on blood component use in surgery, and, arising from that, promotion of a policy of total fractionation as the ideal towards which the transfusion services should aim.<sup>46</sup> Best use of the available scarce resource of whole blood was the driver of the SNBTS's research and development of fractionation. A wider range of more effective therapeutic products became available to haemophilia clinicians.

**21.69** A lively debate began on the best approach to clinical practice. As noted above, in the UK as a whole the use of imported Factor VIII concentrate began before products were first licensed for use and quickly became established. At a joint meeting of the UKHCDO and Blood Transfusion Directors on 31 January 1974, there was a wide-ranging discussion about the relative merits of cryoprecipitate and freeze-dried concentrates. With the exception of Inverness, every Scottish region was represented. Mr Watt represented

<sup>43</sup> Dr Foster – Day 22, page 130

<sup>44</sup> Dr Boulton's statement on the use of blood product concentrates [PEN.015.0054]

<sup>45</sup> Dr Boulton – Day 24, pages 77–79

<sup>46</sup> Paragraph 14.53

the PFC. Factors taken into consideration were: ease of manufacture, recovery from the original plasma, ease of administration, and recovery of activity in patients. Those present at the meeting expressed a clear preference for freeze-dried concentrate if it was available.<sup>47</sup>

**21.70** The question of how much material was likely to be needed led to discussion, with different data and methods being employed by different contributors. A consensus was reached, to the satisfaction of the chairman, Professor Blackburn of Sheffield, on a recommendation to the DHSS as a basis for planning future requirements for Factor VIII in the UK. It was felt that once the new fractionation laboratories in Edinburgh and the Lister Institute were in full production, the needs of the country should be met provided sufficient plasma was available. This view was soon to be confounded in relation to England and Wales, as Figures 21.2 and 21.3 above show. But it appears to be clear that, at this stage, the consensus among the Haemophilia Centre Directors as a group was that the UK was on the brink of self-sufficiency. The rapid increase in demand that was to come about was not anticipated.

**21.71** There were, however, already indications that increasing demand might develop. Several contributors stressed that home therapy was becoming more accepted and widespread, improving the quality of patients' lives. It was recognised that cryoprecipitate was not ideal for that use. Some directors were already buying commercial AHG for home therapy.<sup>48</sup> The minute does not reflect any appreciation that this might affect total demand or demand for NHS products.

**21.72** A paper entitled 'Optimum Use of Available Factor VIII' was considered by the Expert Group on Treatment of Haemophilia at a meeting on 11 October 1974. This paper acknowledged that those present at the last meeting of the Haemophilia Centre Directors were unanimous in preferring freeze-dried concentrate to cryoprecipitate.<sup>49</sup>

**21.73** The disadvantages of cryoprecipitate were again stated: the material must be stored at minus 30°C or below<sup>50</sup> and its potency could not be known before use; it was tedious and time-consuming to make up for use; and to prepare clinical doses, packs or bottles could only be pooled after each had been handled individually. Advantages of the concentrates were known potency and no requirement for freezing. However, there was not sufficient NHS freeze-dried material for wide distribution. Commercial concentrates could be readily purchased but were expensive.

**21.74** Cryoprecipitate was widely available at this time and its use was recommended for the routine treatment of early bleeding in joints and muscles. It was generally thought not to be suitable for home treatment, for which there was a growing requirement. NHS freeze-dried concentrate was recommended for routine surgery and cover for dental extraction, and for home treatment when more material could be made available.

<sup>49</sup> Minutes of Expert Group on the Treatment of Haemophilia, 11 October 1974 [DHF.002.3161]; 'Optimum Use of Available Factor VIII' [DHF.002.3406]

<sup>50</sup> In a hospital setting cryoprecipitate might be stored at minus 70°C: Forbes et al, 'Cryoprecipitate Therapy in Haemophilia', *Scottish Medical Journal*, 1969; 14/1: 1–9 [LIT.001.4018]. For home therapy, Jones et al, 'Haemophilia A Home Therapy in the United Kingdom 1975–6', *British Medical Journal*, 3 June 1978, 1447–50 [LIT.001.0258] required only domestic deep-freeze facilities. See also: Jones P. *Haemophilia Home Therapy*, Pitman Medical 1980, page 78. Other recommendations included minus 18°C. There was no consistency in specifying a maximum temperature for safe storage of cryoprecipitate at this stage.

**21.75** Until NHS supplies of concentrate became adequate, commercial material was recommended for use in three areas:

- For heroic surgery and major trauma; also in the management of serious bleeding in the face of anti-VIII antibodies.
- As back-up when NHS materials temporarily ran out. It was stressed that commercial Factor VIII should only be ordered after all reasonable attempts had been made to obtain NHS materials.
- For the immediate provision of home treatment (in the absence of NHS concentrate) in suitable cases who lived too far from a haemophilia centre to be adequately treated there.<sup>51</sup>

**21.76** As in other areas, control was in the hands of haemophilia clinicians. If the last recommendation might have restricted growth in demand, it failed. When giving oral evidence, Professor Charles Forbes commented that it was not carried out in practice. The advantage of home treatment was that it could be given immediately by the person who had a bleed or their family. He did not think it would have been a good idea that only people who lived a long way from a haemophilia centre should be eligible for home treatment.<sup>52</sup>

**21.77** Professor Ludlam agreed that the last recommendation did not reflect practice in the early 1970s. In his experience, each patient was considered individually, and he did try to help some patients who had severe haemophilia and who travelled very long distances by putting them on to home treatment.<sup>53</sup> However, he did not think that the recommendation had ever operated as a way of rationing treatment.

**21.78** These views reflected a movement in thought towards wider use of home therapy, irrespective of distance to the patient's home. But it was dependent on the availability of concentrate. Efficacy and ease of use of concentrates, coupled with the change to home therapy became closely related aspects of growing demand, both for concentrates generally, and for particular products.

**21.79** Among matters that influenced choice, Professor Ludlam noted that early concentrates (Factor VIII and Factor IX), whether NHS or commercial, were relatively impure and contained large amounts of plasma proteins other than those required for therapy. They were also difficult to dissolve. He told the Inquiry:

[T]he volume of reconstitution was relatively large. The early concentrates were only slightly more purified than freeze-dried cryoprecipitate. The volume of a single infusion might be 200–300mls of concentrate, as compared to 1–5mls with recombinant clotting factors today.<sup>54</sup>

**21.80** For particular patients, this could affect the choice of therapeutic material. In the course of this period the PFC continued to produce Factor VIII and IX concentrates of what was termed 'intermediate purity' while commercial companies began to produce more

<sup>51</sup> Optimum Use of Available Factor VIII [DHF.002.3406]; and Minutes of Expert Group on the Treatment of Haemophilia, 11 October 1974 [DHF.002.3161]

<sup>54</sup> Professor Ludlam's report Edinburgh Haemophilia Treatment Policy [PEN.015.0375] at 0378; and Professor Ludlam – Day 18, pages 42–44

highly purified products. For some patients, the commercial products were preferable to NHS products on clinical grounds. At a meeting of Directors of the SNBTS and Haemophilia Directors on 30 January 1981 held in Edinburgh, reasons for the continued use of commercial products in Scotland were discussed.<sup>55</sup> Haemophilia directors stated that sometimes only a commercial product was available. On other occasions, a high purity product was required and some directors said that the slower solubility of the PFC intermediate Factor VIII was a disadvantage. Some patients experienced more side-effects with the PFC products than with the commercial products. Mr Watt from the PFC acknowledged that there was a solubility problem and expressed hope that an improved product would be available soon.

**21.81** On the other hand, some clinicians were clearly influenced by the view that American concentrates were prepared from blood that was more likely to be contaminated. When asked what the prevailing view was in Edinburgh regarding the difference between US concentrates and NHS concentrates, Dr Boulton referred the Inquiry to Richard Titmuss' book *The Gift Relationship* which was published in 1970. He said:

[I]t very clearly describes the risk of using blood from donors who are paid, that is the profit-making donor centres and the blood from the non-profit-making donor centres, who used volunteer donors in America .... The book very clearly established the greater risk from using blood – this is not fractionated products but just straight blood – from donors who are paid compared with donors who are not paid, and although there has been more than one magnitude of difference drop in the risk of paid and non-paid blood donors, that debate is still going on to this day, as far as I know.<sup>56</sup>

**21.82** By 1980, Dr Boulton thought that one would be very aware of the problems of using blood and fractionating plasma from donors who were paid. For him, the 1975 World in Action programme described later highlighted a known problem:

[I] think that one was certainly aware that there were risks associated with using commercially obtained plasma from companies who were bleeding their donors and paying them in America or indeed, on reflection, in Austria.<sup>57</sup>

**21.83** The data on use of products overall have to be understood as subject to these, and other factors, affecting individual clinical choice. The selection of products for home therapy reflected a complicated mixture of influences: it was not necessarily straightforward, and individual clinicians might reasonably differ in their views and preferences.

## The development of home treatment

### *Early to mid-1970s*

**21.84** As matters developed, the move towards home treatment accelerated throughout the UK because haemophilia clinicians thought it to be in the best interests of individuals who would benefit from it. In oral evidence Dr Mark Winter outlined a typical example of a patient's experience of treatment in hospital with cryoprecipitate.<sup>58</sup> The problem would arise out of hours. There would be a good chance that the haemophilia centre would

<sup>55</sup> Minutes of meeting of SNBTS Directors and Haemophilia Directors, 30 January 1981 [SNB.001.5055] at 5055–56

<sup>56</sup> Dr Boulton – Day 24, pages 17–18

<sup>57</sup> Ibid page 18

<sup>58</sup> Dr Winter – Day 15, pages 79–80

be closed so that the patient would have to attend a hospital casualty department. It would be extremely unlikely that the doctor seeing him would know anything about haemophilia so there would be a delay while the doctor found out. After consulting the on-call consultant haematologist, the blood transfusion department would be contacted and asked for cryoprecipitate to be prepared. So the patient could be in the hospital for 6–8 hours before the doctor tried to inject the cryoprecipitate with a very large needle rather than the small butterfly needle which was perfectly suitable. Dr Winter said:

[I] have laboured this point because it was a very harrowing experience. I have never, in all my years of haemophilia, ever heard a patient say, 'I went to casualty with a bleed and everything went well'. It never does, for pretty obvious reasons. These departments are very busy. The doctors know nothing about the condition, and haemophilia is rare.

So not only was cryoprecipitate not a very good medical treatment, for the patients it was a pretty dreadful experience having to go to hospital to have the treatment. So that was why, when one spoke to patients or you went to residential Haemophilia Society weekends, there was a very strong, very strongly expressed view from the patients of, 'We want concentrate, not cryoprecipitate and we want it to be British concentrate, not American'.<sup>59</sup>

**21.85** Some haemophilia patients could react to protein impurities in the cryoprecipitate resulting in quite an unpleasant experience for the patient. Dr Winter said: 'Over the period of an hour they might shake and shiver and run a fever and have muscle aches and feel generally unwell'.<sup>60</sup>

**21.86** He said that it was a major revolution when concentrates became available: they were so much easier to use than cryoprecipitate and unlike cryoprecipitate did not need to be deep frozen. At this early period, nobody had a freezer in their homes. Factor VIII and IX concentrates could be kept in small volumes in a domestic refrigerator so home therapy became possible.

**21.87** Home therapy could start from the age of about three, depending on the state of the child's veins and the competence of the parents, who were taught how to inject the patient with concentrate. The patient would then go on home therapy for the rest of his life with a comprehensive clinical review every two to three months, depending on the severity of the disorder. Dr Winter said:

Prior to that, schooling in particular had been so variable an experience for children with haemophilia that there was actually a dedicated boarding school in Hampshire for patients with haemophilia, called the Lord Mayor Treloar School, where many of my patients went. When the concentrate came in, the boarding aspect of that school was no longer deemed to be necessary.

So this was a very major breakthrough. It enabled patients to get control back over their lives, to be on home therapy, and in retrospect we now call this period 'the golden interval'. This would be sort of 1973 until we entered the years of viral contamination problems, say five or six years later.

---

<sup>59</sup> Ibid page 80

<sup>60</sup> Ibid pages 80–81

In retrospect it seems like a golden time where there was a disease which for 2000 years had had no treatment and then suddenly there had been this enormous quantum leap forward. People were getting decent jobs, having a decent amount of time at school, getting early treatment at home for their bleeds. That was causing less joint problems.

**21.88** Parents were taught how to recognise an episode of bleeding. For joint bleeding, heat was a good indicator that there was bleeding. Parents were taught to compare, for example, knees – the knee with a joint bleed would be a lot hotter than the other one. A child would not want to move the joint if there was a joint bleed so it should be pretty obvious that the child had a bleed.

### *First assessments of consequences of home treatment*

**21.89** By 1975 home treatment programmes were being run by several haemophilia centres. Over 1975 and 1976, Drs Jones,<sup>61</sup> Forbes, Fearn and Stuart compiled data on home treatment for patients with haemophilia, including information about access to treatment. Questionnaires were completed by Haemophilia Directors throughout the UK. The number of patients on or in training for home treatment increased from 267 to 488 in the two years, and a further 241 haemophiliacs were considered suitable for home therapy by the end of 1976. About 60% of patients with Haemophilia A were receiving or being considered for home treatment in 1976. Home treatment had become a major part of the programme of therapy. In 1978, they published a paper in which they noted that:

- The related demand was more than half the estimated total national requirement.
- There were many variables requiring research.<sup>62</sup>

**21.90** It was also noted that there was a rise in prophylaxis, expected to be sustained in 1977. There was a continued shortfall in the production of NHS concentrate from the voluntary donor system of the blood transfusion service. In 1976 there were still some areas in the UK where home treatment had not been implemented.

**21.91** The paper proceeded:

Home treatment for many of the haemophiliacs in the United Kingdom would have been impossible without recourse to factor VIII concentrates prepared by pharmaceutical companies. About 55% of the blood product used for home treatment in 1976 was imported, importation being necessary because of continued shortfall in the production of NHS concentrate from the voluntary donor system of the Blood Transfusion Service .... In 1976 the Department of Health announced that the UK requirement for factor VIII concentrate would be met from NHS sources by mid-1977 after the grant of an additional £0.5m to the Blood Transfusion Service.<sup>63</sup> This target has clearly not been met, nor could it have been in the absence of the necessary financial aid to increase fractionation capacity .... The difficulty of implementing home treatment in

<sup>61</sup> Peter Jones was then a consultant paediatrician working at the Newcastle Haemophilia Reference Centre, Royal Victoria Infirmary, Newcastle upon Tyne; he was also Chairman of the UKHCDO's working party on Home Therapy. His handbook for haemophilia patients entitled *Haemophilia Home Therapy* was published in 1980.

<sup>62</sup> Jones et al, 'Haemophilia A home therapy in the United Kingdom 1975-6', *British Medical Journal*, 3 June 1978; 1447-50 [LIT.001.0258]

<sup>63</sup> HC Hansard, Vol 884, col 392, 26 February 1975 [PEN.012.0183]

some areas is reflected in the continued use of cryoprecipitate, which, despite its disadvantages, remained the only product available for 15% of haemophiliacs in 1976.<sup>64</sup>

**21.92** Professor Forbes advised the Inquiry that he and his co-authors wanted to document the enormous long-term advantage to individual patients who had been on home therapy.<sup>65</sup> Home therapy reduced complications and bleeds. In relation to the high number of patients on or awaiting home therapy at the end of 1976, Professor Forbes commented:

Yes, it was a very popular move and this, of course, is before all the horrendous complications came on stream. So this was the golden age, in which we actually seemed to be doing something valuable for these patients.<sup>66</sup>

**21.93** In the Discussion section of the article it was commented that: 'Perhaps the most disturbing aspect of the 1976 inquiry was the lack of adequate follow-up in some centres'.<sup>67</sup> Professor Forbes said that they were looking at follow-up of the number of joint bleeds and joint deterioration and so on but of more concern trying to ascertain whether all these plasma products had a downside. It was to become clear that they did, but that was for the future. Liver function tests were among the follow-up tests carried out. Professor Forbes thought that these tests would have been part of good follow-up. He said:

I'm pleased that we had put that in. We had no idea what would happen. And that was major concern for hepatitis, and for perhaps other infections that we didn't know about.<sup>68</sup>

**21.94** The paper reflected clearly that so far as haemophilia clinicians were concerned, the expectation was of continued and increasing use of factor products, including use in home therapy, with a significant dependence on imported products. Cryoprecipitate was not expected to meet the demand. Commentators, such as Professor Forbes, were sufficiently concerned about risk to recommend follow-up of concentrate therapy by liver function tests, but they had no means of knowing at that stage what the risks were.

### *Home therapy mid-1970s to 1982*

**21.95** Support for home therapy strengthened in the remainder of this period. Home treatment was discussed in Dr Michael Willoughby's textbook on paediatric haematology written in 1976 and published in 1977. Dr Brian McClelland advised the Inquiry that he knew Dr Willoughby's book very well. He said that, although out of date, it was an extremely good book where you could still find the information that you wanted when you wanted it.<sup>69</sup> The textbook offered the Inquiry a useful perspective on the treatment of children with haemophilia in the 1970s.

<sup>64</sup> Jones et al, 'Haemophilia A home therapy in the United Kingdom 1975-6', *British Medical Journal*, 3 June 1978; 1447-50 [LIT.001.0258] at 0260

<sup>66</sup> Ibid page 58

<sup>67</sup> Jones et al, 'Haemophilia A home therapy in the United Kingdom 1975-6', *British Medical Journal*, 3 June 1978; 1447-50 [LIT.001.0258] at 0260-61

<sup>68</sup> Professor Forbes – Day 17, page 60

<sup>69</sup> Dr Brian McClelland – Day 21, page 124; for excerpts from Dr Willoughby's book see [PEN.016.1062]

**21.96** In his book Dr Willoughby commented that commercial and NHS concentrates had advantages over cryoprecipitate in respect that they could be stored at 4°C and could be carried by the patient when travelling – extending the meaning of ‘home’, but giving emphasis to the flexibility of the product.<sup>70</sup> In respect of home treatment, he referred to programmes of home transfusion in the early 1970s in the UK and the USA. In a 1970 study carried out in the USA, patients’ preliminary experience showed a reduction in the number of school or work days lost as the patients were spared frequent ‘time-consuming and psychologically undesirable’ visits to hospital.<sup>71</sup> A pilot study was carried out in 1972 in the UK for patients suffering very frequent haemorrhage (at least once every two weeks). Dr Willoughby wrote:

Le Quesne *et al* (1974) in the UK and Levine (1974) in the US have similarly come to the conclusion that home treatment is highly efficacious in reducing the morbidity of haemophilia and improving the quality of life. No increase in utilization occurred except in patients previously undertreated.<sup>72</sup>

**21.97** Professor Forbes agreed with the suggestion that in the late 1970s home treatment was thought to be the way ahead. Most people who were on home treatment programmes eventually had better joints and were less crippled. Patients who had a bleed could get their treatment instantly rather than wait for an ambulance, be taken to an inappropriate casualty department, wait to be assessed and many hours later get treatment.<sup>73</sup>

**21.98** Home treatment also improved patients’ experience of life. Expectations of haemophilia patients were discussed at the meeting of the UKHCDO in January 1977.<sup>74</sup> Mr John Prothero from the Haemophilia Society said that the society aimed to encourage those with haemophilia to lead a full life within a reasonable range of activities. As treatment improved, the patients’ expectations widened. Mr Prothero said that home therapy had helped a great deal, permitting patients to go on holiday away from their centre and to travel on business. Education was discussed and it was noted that some local education authorities and headmasters had not allowed a boy with haemophilia to go to an ordinary school. Mr Prothero thought that by early 1977 the majority of haemophilia patients were not barred from attending ordinary schools.

**21.99** Dr Charles Rizza talked about 13 severely affected Christmas disease patients who had received prophylactic treatment with Factor IX concentrate and commenced home treatment.<sup>75</sup> He said the treatment had been very effective enabling two of his patients, young twin brothers, to never miss school.

**21.100** Several publications were available or in preparation at this point providing guidance to patients and clinicians on home therapy, including a handbook by Dr Jones, Newcastle, and a Haemophilia Society handbook.<sup>76</sup>

*The early 1980s: An Edinburgh insight*

**21.101** As the figures earlier in this chapter show, there was increasing demand for Factor VIII concentrate in 1979–82 (rest of the UK) and 1980–82 (Scotland). As more fully discussed below from paragraph 21.260 onwards, there were variations in practice across Scotland. A practical illustration of what was happening in Edinburgh and south east Scotland at the time was given by Professor Ludlam and Dr Boulton. Dr Davies, Professor Ludlam’s predecessor, had consistently used cryoprecipitate and PFC Factor VIII, predominantly cryoprecipitate.

**21.102** When Professor Ludlam and Dr Boulton arrived in Edinburgh in 1980, increasing demand for concentrates for home therapy became a significant issue. Professor Ludlam told the Inquiry that in Edinburgh, in contrast to Glasgow under Drs Forbes and Willoughby, there was no particular policy in relation to home treatment. When there was a plentiful supply of Factor VIII, home treatment was for anyone who was competent to give it to themselves and bled sufficiently frequently that they needed it.<sup>77</sup> However, it was clear that home treatment was in demand, and it was increasingly provided over time.

**21.103** In a written statement, Professor Ludlam noted that at the beginning of 1980 there were only six patients on home treatment out of a population of 187 patients registered with Haemophilia A. He said: ‘There was a lot of enthusiasm for home treatment and I was continually being asked about it’.<sup>78</sup> The number on home treatment in Edinburgh increased from six in 1980 to 47 in 1989.

**21.104** Professor Ludlam and Dr Boulton did not favour cryoprecipitate for home treatment. Dr Boulton agreed with the view expressed by other clinicians that cryoprecipitate was very difficult for home therapy. He said:

It was not totally unsuitable. It could be used. But the patients, and if they were a young boy, the patient’s family, the parents, would need quite careful and specific training and monitoring so to do. And so it was only really practical in families (a), who were relatively well trained and (b), probably in fairly close proximity to the hospital in case things went wrong.<sup>79</sup>

**21.105** Professor Ludlam said that he was not prepared to take the risk of giving patients cryoprecipitate at home.<sup>80</sup> Storage requirements and the inconvenience of administration made it an unsuitable material, in his view. The patient would have to have a deep-freeze and a water bath that could be heated to 37°C to melt the individual frozen units of cryoprecipitate. Professor Ludlam emphasised the need for a clean, if possible sterile, environment, and careful control of temperature for optimal results.<sup>81</sup> If the water was too hot the proteins in the frozen plasma would congeal, a bit like egg white. Professor Ludlam described to the Inquiry what the patient at home would have to do:

They ... would take out of the deep freeze 15 packs of cryoprecipitate, put them in the water bath. They take about a quarter of an hour to melt. And then each of those packs has to have a tube put into it and the melted cryoprecipitate rolled out. Because they are polythene bags, you can roll them up and squeeze the cryoprecipitate out. You do that repeatedly 15 times, squeezed out into a

<sup>77</sup> Professor Ludlam – Day 18, page 65

bigger bag. You would then have to hang that up, connect it to a drip set, like giving a conventional blood transfusion, the patient would then have to put the needle into their vein and connect up the transfusion set to the tubing on the needle. And it would take about half an hour/40 minutes to run in.<sup>82</sup>

**21.106** He said that treatment with cryoprecipitate was straightforward in hospital:

But in a home setting, well – I wasn't prepared to let patients have treatment at home with cryoprecipitate for all these reasons. But perhaps the most important reason ... is the reactions. A lot of patients getting cryoprecipitate had reactions. Often these were mild and they would take an antihistamine beforehand, but I was looking at some information a day or two ago, suggesting that actually cryoprecipitate should only be given where adrenaline is available, and adrenaline is when you get an acute life-threatening allergic reaction, what's called an anaphylactic reaction. So for these reasons I wasn't keen and I did not have a home therapy programme based on a cryoprecipitate. I concede other places did and it seemed to work for them, but it was logistically difficult.<sup>83</sup>

**21.107** In a paper provided to the Inquiry after the Oral Hearings,<sup>84</sup> Professor Ludlam stated that home therapy critically depended on a ready and reliable supply of concentrate. If there was a reduction in the availability of concentrate, hospitals could adapt by substituting cryoprecipitate for treatment. This was not an option for those on home therapy. If there was a lack of concentrate, home therapy had to be discontinued. Professor Ludlam noted that this was very disturbing and disruptive for patients (and their families) and was to be avoided if at all possible. Many of his patients could not get home therapy because there was not an adequate supply of concentrate. In England the majority of patients were treated with both NHS and commercial products. He preferred not to expose patients who had only received NHS concentrate to commercial product.

**21.108** Professor Ludlam said that home treatment could start from the age of four or later, depending on the child. He explained the difficulties of treating babies:

A child with severe haemophilia usually starts to bleed around the age of nine months when they start to crawl around and walk and fall over. And so to begin with, they only get occasional bleeds, perhaps every month or so, and so they need treatment and the baby is distressed from the pain of the bleed and that makes their veins constrict a bit. They have very small veins, they may have chubby arms, and it is not easy to treat small babies, give them an intravenous infusion of anything. The clotting factor concentrate is of some volume and therefore it can be very traumatic for everybody, treating very small babies.<sup>85</sup>

**21.109** He maintained Dr Davies' policy of using NHS material for the treatment of children.<sup>86</sup> He commented on his predecessor's preference for NHS concentrates:

[Dr] Davies had a policy of not using commercial concentrates because of the uncertainty about hepatitis viruses in the concentrates derived from plasma

collected in the United States and elsewhere .... The disadvantage of this policy was that there was relatively little factor VIII concentrates available and this [was] significantly delaying the introduction of home treatment for many eligible patients. I impressed upon SNBTS my desire to have more factor VIII concentrate.<sup>87</sup>

**21.110** But Professor Ludlam pressed ahead with home treatment. His policy in commencing home treatment at age four or later was different from Dr Winter's, but not materially.

**21.111** Jones and colleagues expressed a similar view about the wider picture.<sup>88</sup> Concentrate was needed to support home treatment: it was not until freeze-dried concentrates were more freely available that large-scale home treatment programmes became possible, in their view. Given the limited supplies of NHS product, Dr Jones thought that home treatment for many of the haemophilia patients in the UK would have been impossible without recourse to commercial Factor VIII. In Scotland, that was the position for a short time in the early 1980s.

### Prophylactic treatment of haemophilia

**21.112** The practice of prophylaxis was also initiated in the 1970s although Dr Winter thought that the prophylactic programme did not really get going until the 1980s.<sup>89</sup>

**21.113** In his textbook on paediatric haematology, Dr Willoughby discussed prophylactic treatment.<sup>90</sup> He wrote:

Prophylactic administration of Factor VIII or IX in severely affected patients has met with greater success. Clearly this is reserved for patients with quite exceptionally severe and frequent haemorrhages ....

The rationale for intermittent prophylactic replacement therapy is that spontaneous haemorrhage is only seen in patients with Factor VIII levels below 1–2 per cent and infusions of concentrates at 36 to 48-hour intervals can keep the concentration above this level for most of the time ....

**21.114** At the UKHCDO meeting on 13 January 1977 there was a discussion about a trial of prophylactic treatment of severely affected haemophilic boys at Lord Mayor Treloar School, Hampshire.<sup>91</sup> The boys were treated with cryoprecipitate, Kryobulin and Hemofil. All but one of the boys had a fairly substantial reduction in the number of bleeds. Not all of them preferred prophylaxis to 'on demand' treatment but it was suggested that the two boys with good results who wanted to stop prophylaxis might have forgotten what a bad bleed was like. Professor Stewart from the Middlesex Hospital in London commented that prophylactic treatment for haemophilia patients should not be entered into on a large scale until there was sufficient evidence that it was beneficial to the patients. The trial was said to be aimed at providing information for future discussion, and not with the

intention of immediate implementation. It was, in the event, the beginning of a new form of demand for therapeutic products that was heavily dependent on factor concentrates.

**21.115** When Professor Forbes was asked why he thought some people appeared to have reservations about prophylaxis, he replied: 'I think the concern was that it was the huge amount of exposure to plasma products that it would entail'.<sup>92</sup>

**21.116** At a meeting of the UKHCDO on 20 and 21 November 1979, Dr Jones presented a report from the Home Therapy Working Party. Professor Stewart asked whether there had been any move to find out if prophylactic treatment really did any good. Dr Jones responded by saying: '[F]or haemophilia A patients, limited prophylaxis was very effective indeed but it must be for a very good reason. One could spend less on prophylactic treatment than on on demand treatment in some instances'.<sup>93</sup>

**21.117** Professor Forbes commented on Dr Jones' remarks:

This was a very interesting concept because people thought it would be very expensive giving routine treatment but in fact it reduced the amount of bleeding so that over a period of time the number of units of factor VIII given reduced, and of course, the joint damage and the other things reduced as well. So it seemed to be a very efficient and effective way of proceeding.<sup>94</sup>

**21.118** Professor Ian Hann, who took up the position of Consultant Paediatric Haematologist and Oncologist at the Royal Hospital for Sick Children, Yorkhill, Glasgow in January 1983, told the Inquiry that he thought that his predecessor Dr Willoughby was well ahead of his time with regard to his belief that prophylaxis was the way forward. There was a great deal of scepticism over whether it was efficacious or practical, a view shared at that time by Professor Hann. He now considered that Dr Willoughby was right.<sup>95</sup>

**21.119** At Yorkhill, Professor Hann carried out short-term prophylaxis in patients who had bursts of bleeding problems or a very severe bleed which did not settle down. He said:

So we carried out short-term prophylaxis, usually for several months or a little longer, during which we could verify a supply and then, in almost all of these cases, we had to discontinue prophylaxis.<sup>96</sup>

**21.120** They never had enough product to carry out long-term prophylaxis. There was also doubt at the time whether long-term prophylaxis would work.

**21.121** When Professor Hann was working at the Royal Free Hospital in London (prior to taking up the post in Glasgow)<sup>97</sup> his colleagues were worried initially that early prophylaxis might increase the risk of developing inhibitors, the antibodies to factor proteins which make a patient resistant to treatment. It took years, probably until nearly 1990 or thereafter, for people to accept that prophylaxis worked. Professor Hann moved to Great Ormond Street Hospital in London in 1987 and his unit was the first to get all patients onto recombinant prophylaxis in about 1990.

<sup>94</sup> Professor Forbes – Day 17, pages 67–68

<sup>95</sup> Professor Hann – Day 21, page 28

<sup>96</sup> *Ibid*, pages 32–33

<sup>97</sup> Professor Hann was a lecturer in haematology at the Royal Free Hospital from May 1980–December 1982.

**21.122** The evidence indicates that the emergence of prophylactic treatment had begun to influence demand at this period in some cases, but there is insufficient evidence to suggest that it had made a huge impact on total demand by 1982.

**21.123** The discussion so far shows that there was persistent and significant growth in the use of Factor VIII products throughout the period to 1988, and points to some of the factors driving that growth:

- Meeting the hidden demand related to patients' needs for treatment with coagulation factor products that had not previously been available, or available in sufficient quantity, to provide for the treatment of all haemophilia patients.
- Changing patterns of provision as new products became available.
- The ability to develop therapy regimes, and in particular home treatment, as concentrates became more readily available.
- To some extent, the start of prophylactic therapy.

**21.124** In parallel with these developments, there was growing understanding that there was a price to pay. In Professor Cash's colourful expression, there were no therapeutic roses without thorns.

### Transmission of hepatitis

**21.125** The first part of that price was exposure to risk of transmission of homologous serum jaundice or serum hepatitis.<sup>98</sup> The risk was widely recognised, but little understood by haemophilia clinicians and commentators on therapy in the early part of the period.<sup>99</sup> The second part of the price was exposure to the risk of developing inhibitors. By the end of the 1960s both risks were the subject of comment. At this stage, before the licensing and general importation of commercial concentrates, Factor VIII concentrate therapy was provided by cryoprecipitate and early forms of AHG.

**21.126** In 1967, the Haemophilia Centre Directors decided at a meeting of representatives of all 36 of the haemophilia centres that then existed to set up a study of the incidence of transfusion hepatitis and the incidence of inhibitors<sup>100</sup> – 'two most alarming, but unrelated, complications of treatment of patients with coagulation defects' – in patients treated for Haemophilia A and B.<sup>101</sup> The study appears to have been taken forward by the Cryoprecipitate Working Party of the MRC Blood Transfusion Research Committee.<sup>102</sup> A progress report, most likely prepared by Dr Rosemary Biggs, was presented to the Haemophilia Centre Directors on 5 April 1971.<sup>103</sup> The study represented a significant initiative in the late 1960s and early 1970s in hepatitis research.

<sup>98</sup> The early history of developing knowledge of the risk of transmitting hepatitis associated with therapeutic products is discussed in Chapter 14, *Knowledge of Viral Hepatitis 1*.

<sup>99</sup> See, for example, Maycock et al, 'Further Experience with a Concentrate Containing Human Antihæmophilic Factor', *British Journal of Haematology*, 1963; 9:215 [LIT.001.0063]. The focus was on short-term reactions to treatment, especially jaundice, reflecting a lack of understanding of the natural history of transfusion transmitted hepatitis. Dr Smith suggested that manufacturers of therapeutic products had a distinctive appreciation of the risks of virus transmission: Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1554

<sup>100</sup> Antibodies inhibiting the efficacy of factor therapy.

<sup>101</sup> Agenda for meeting of Haemophilia Centre Directors, 5 April 1971, Appendix 1 [DHF.001.1811] at 1812

<sup>102</sup> Ibid [DHF.001.1811]

<sup>103</sup> The letter [DHF.001.1810] covering the Agenda for the meeting of Haemophilia Centre Directors on 5 April 1971 came from the Oxford centre, where Dr Biggs was then Director. The letter says 'I have prepared a written report...'. The report, [DHF.001.1811] at 1812, contains introductory material almost identical to the 1974 article by Dr Biggs discussed at paragraph 21.139. It therefore seems likely that Dr Biggs was responsible for the report to the 5 April 1971 meeting.

**21.127** The progress report presented data for 1969 (and therefore before imported commercial concentrates had arrived in the UK). So far as disclosed in the report, prior structured research into hepatitis in haemophilia appears to have been very limited. The narrative provides an insight into contemporary thinking:

Transfusion hepatitis is thought to be a virus infection transmitted to the recipient by the donor plasma. There is every reason to suppose that the virus is contained in the various protein fractions used to treat haemophilia and Christmas disease (cryoprecipitate, human antihaemophilic globulin ... and factor-IX concentrate). The incidence of the virus in the donor population may be of the order of 1 per 1000 ....<sup>104</sup>

**21.128** By this stage, a number of preparations had been introduced, and there are difficulties with the terminology used to identify them. In the late 1960s, AHG (in Scotland largely Cohn Fraction I) was a low potency product sometimes called 'concentrate'. In the early 1970s, commercial pharmaceutical companies introduced a true concentrate, of variable but increasing potency, sometimes referred to as AHG. Where possible, the distinctions will be noted.

**21.129** Clinicians were asked to record the varieties and amounts of therapeutic materials used and 'the incidence of inhibitors and jaundice'.<sup>105</sup> Progress with the study is discussed in Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraphs 14.16 to 14.19. The focus was on 'clinical jaundice'. No attempt was made to record sub-clinical hepatitis since it was thought that the important feature from the point of view of the patients was clinical illness. For 1969, it was reported that 29 patients (2.8%) were jaundiced.<sup>106</sup> Three patients had died. Two of the three had been treated with cryoprecipitate only. The third had been treated with cryoprecipitate and 'concentrate' (in this case AHG, the low potency product).<sup>107</sup> A more detailed examination of the records of haemophilia patients in Oxford showed that seven had developed jaundice.<sup>108</sup> Other data, derived from 60 patients treated at the Oxford centre, indicated the incidence of Hepatitis B associated antigen and antibody. It was reported that, of the sample of 60 patients, 11 had a positive test for Hepatitis B antigen or antibody and that of these only one developed 'clinical hepatitis'.<sup>109</sup> In retrospect, it is very likely that the vast majority of these jaundiced patients had been infected with the Hepatitis B virus (HBV). During the period covered by the data reported (1969 and 1970), the first, insensitive, tests for the so-called 'Australia antigen', later to be identified as the Hepatitis B antigen (HBsAg), were available. The antigen had been identified in 1967 as associated with serum hepatitis virus.<sup>110</sup>

**21.130** The reports identified a fundamental dilemma for clinicians that was to persist, in one form or another, for decades:

The clinical value of free and early treatment of haemophilic patients in the saving of life and the prevention of crippling is now well established. This treatment is known to carry two main hazards: (1) the transmission of viral

<sup>110</sup> Blumberg et al, 'A Serum Antigen (Australia Antigen) in Down's Syndrome, Leukemia, and Hepatitis', *Annals of Internal Medicine*, 1967; 66:924-931 [PEN.002.0764]

hepatitis; (2) the development of specific antibodies against coagulation factors.<sup>111</sup>

**21.131** At this early stage, the risks were thought to be low. On the basis of the data from the 60 Oxford patients, it was reported that whereas about 18% of individuals had evidence of infection with HBV at this time, only 2.8% had overt illness. The view expressed was that:

Although the surveys do not involve large numbers it is likely that the prevalence of hepatitis virus in the materials used to treat haemophiliac patients is approximately as expected. The overall low incidence of clinical illness is presumably due to the fact that the patients became immunized in childhood.<sup>112</sup>

**21.132** The research findings led to the incorrect conclusion that patients with coagulation defects were very resistant to clinical infection with the HBV. For haemophilia clinicians, concerned to balance the advantages of therapy with the materials available against the risks of transmission of infection, the emphasis on what they could observe in treating patients is clear. As in cases of post-transfusion hepatitis, the focus in discussing hepatitis in haemophilia patients treated with blood products (cryoprecipitate or concentrate of any generation) was on acute, clinically observed, hepatitis, and in 1971 it was thought that this was largely due to HBV infection.<sup>113</sup> A low number of diagnosed cases was taken to indicate a low risk overall. However, an infection that escaped identification on the screening tests available could not be taken into account. The possibility of any form of chronic disease was ill understood and little appreciated.<sup>114</sup> At this time (up to the early 1970s) it was thought and hoped that development of good (screening) tests for HBV would lead to a very great reduction in post-transfusion hepatitis or its equivalent in haemophilia patients.

**21.133** So far as concerns the second hazard, the author, Dr Biggs, had reservations about data on the development of specific antibodies against coagulation factors (inhibitors): it was thought to be fragmentary and inconclusive. There was, to that date, no evidence of a steady increase in patients with antibodies. Of the patients seen at the centres in 1968, 5.47% had antibodies, and in 1969 the figure was 6.1%, but those were the only two years for which there were data.<sup>115</sup>

**21.134** The progress report stated:

Hepatitis transmission must be related to the number of 'donor exposures' of the patients. This number will increase with the use of dried concentrates made from large pools of donors. These concentrates have advantages in treatment in that the potency is known and they are convenient to make up and administer. The problem in recommending an increased manufacture of these lies in the possible increase in hepatitis and antibodies. From the point of view of clinical hepatitis this danger seems to be small though the high

<sup>111</sup> Agenda for meeting of Haemophilia Centre Directors, 5 April 1971, Appendix 1 [DHF.001.1811] at 1820

<sup>112</sup> Ibid [DHF.001.1811] at 1816

<sup>113</sup> In respect of clinically observed hepatitis, largely in patients with jaundice, it was probably correct that the majority of cases were indeed due to Hepatitis B. As was learned much later, a far smaller proportion of patients with NANB Hepatitis/HCV presented with overt jaundice.

<sup>114</sup> Some commentators noted long-term sequelae, eg prolonged viraemia: see 'More about Australia Antigen and Hepatitis', *The Lancet*, 15 August 1970; 347–349 [DHF.002.7334]

<sup>115</sup> Agenda for meeting of Haemophilia Centre Directors, 5 April 1971, Appendix 1 [DHF.001.1811] at 1821

incidence of Australian antigen and antibody in haemophiliacs suggests that they do become infected. We feel that the increased risk of clinical illness is not so great as to overbalance the advantages of the use of concentrates.<sup>116</sup>

**21.135** In practice, haemophilia therapy had come to be dependent on blood products. Before the discovery of cryoprecipitate (in the mid-1960s) fraction concentrates (introduced in the late 1950s) were in short supply and usually reserved for surgery and the treatment of major complications in hospital. Most haemophilia patients had received fresh frozen plasma for the routine management of haemorrhage. The introduction of cryoprecipitate allowed outpatient treatment for all but the most severe bleeding episodes.<sup>117</sup>

**21.136** Changes in clinical practice inevitably increased the numbers of patients exposed to blood products at a time when knowledge of the risks had not developed. The discovery of the Australia antigen, in Professor Cash's words in 1972, heralded an explosive research effort in which clinicians, biochemists, geneticists, microbiologists and immunohaematologists all made important contributions to developing knowledge.<sup>118</sup> At the same time, the ready availability of large-pool concentrates heralded an explosion in their use.

**21.137** The WHO scientific group's report 'Viral Hepatitis' reflected progress in the understanding of the clinical, epidemiological and immunological behaviour of Hepatitis B.<sup>119</sup> One aspect of that progress was developing understanding that not all cases of post-transfusion hepatitis were caused by Hepatitis B infection, and that, as more Hepatitis B carriers<sup>120</sup> were eliminated from serving as blood donors, the proportion of cases due to other types of hepatitis would increase.<sup>121</sup> The report noted that some carriers had been found to have liver abnormalities ranging in severity from minor changes in the nucleus of the cell to severe hepatitis and cirrhosis. There was also a changing picture of the prevalence of HBsAg in apparently healthy blood donors. Prevalence was said to vary with such factors as the socio-economic status and sex of the donor, whether he was a volunteer or paid, and whether he lived privately or in an institution. Antigen had been detected most frequently in males in the younger age-groups. And the association between a history of clinical jaundice and a chronic HBsAg carrier state was breaking down.<sup>122</sup>

**21.138** In Scotland, the report of the joint symposium held by the Royal College of Physicians of Edinburgh and the Royal Society of Edinburgh in 1972 indicated the state of knowledge among transfusion specialists at that time. The risks of transmitting serum hepatitis and of inducing antibodies (inhibitors) associated with Factor VIII products were recognised as established.<sup>123</sup> Other BTS studies in the early 1970s, in England and Scotland, sought to determine the prevalence of Hepatitis B infection in the general population,

and in specific cohorts such as prisoners, in connection with blood collection policy.<sup>124</sup> In transfusion circles, there was increasing interest in the relationship between transfusion and hepatitis infection.

**21.139** The second published report of Dr Biggs' study, in 1974, again related to the incidence of jaundice in patients treated for Haemophilia A and B (Christmas disease). The period covered was 1969 to 1971.<sup>125</sup> By the date of publication, with the benefit of improved testing and screening for HBV, it was thought that more than one blood-borne virus might be responsible for post-transfusion hepatitis. But the focus for haemophilia doctors, exemplified in Dr Biggs' report, remained on clinically apparent disease and on Hepatitis B.<sup>126</sup> The diagnostic features of clinical jaundice identified were identical to those reported at the Haemophilia Centre Directors' meeting on 5 April 1971, and related to the acute illness. The possibility of chronic liver disease arising from one or more of the post-transfusion hepatitis viruses was barely recognised by haemophilia doctors in the early 1970s, even as late as 1974.

**21.140** The paper recognised the clinical value of treatment of haemophilia patients, and the known hazard of transmission of serum hepatitis. It stated:

The data on hepatitis suggest that severely affected and multi-transfused patients with coagulation defects do not have a high incidence of clinical illness associated with jaundice. Present calculations suggest that if all of the patients were exposed to virus contained in pools of plasma 4–5% of them might develop clinical illness. The proportion of patients exposed to virus is likely to decrease in future rather than to increase since donations grossly infected with Hepatitis B antigen will be excluded by universal donor screening.<sup>127</sup>

**21.141** It was still thought that patients developed some immunity to the virus from multiple transfusions.<sup>128</sup> The paper also suggested that large donor pools might be a positive advantage because the virus would be diluted and would also contain Hepatitis B antibodies (conferring passive immunity to HBV infection with these antibodies).<sup>129</sup>

**21.142** The incidence of anti-HBs found by Dr Biggs in haemophilia patients treated with blood products showed that a proportion did become infected by HBV. Dr Biggs' 1974 paper recognised that factor concentrates generally were associated with a risk of transmitting hepatitis. It was the nature and the scale of the problem that were not captured. The publication of the MRC study (chaired by Dr Maycock) in 1974 helped to continue the erroneous perception among haemophilia clinicians that post-transfusion hepatitis was rare in the UK.<sup>130</sup> Others took a different view,<sup>131</sup> but the balance of opinion in the UK seems clearly to have been reflected in these major studies.

<sup>124</sup> See Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraphs 14.20–14.26

<sup>125</sup> Biggs, 'Jaundice and antibodies directed against Factors VIII and IX in patients treated for haemophilia or Christmas Disease in the United Kingdom', *British Journal of Haematology*, 1974; 26:313 [LIT.001.0099]. See Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraphs 14.16–14.19

<sup>126</sup> Biggs, 'Jaundice and antibodies directed against Factors VIII and IX in patients treated for haemophilia or Christmas Disease in the United Kingdom', *British Journal of Haematology*, 1974; 26:313 [LIT.001.0099] at 0102

<sup>127</sup> *Ibid* [LIT.001.0099] at 0111

<sup>128</sup> This was indeed correct in some patients who lost HBsAG, but retained HBsAB, in their blood. But this distinction was not understood for some years after the date of this paper.

<sup>129</sup> Biggs, 'Jaundice and antibodies directed against Factors VIII and IX in patients treated for haemophilia or Christmas Disease in the United Kingdom', *British Journal of Haematology*, 1974; 26:313 [LIT.001.0099] at 0111

<sup>130</sup> See Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraphs 14.20–14.26

<sup>131</sup> Buchholz, 'Blood Transfusion: Merits of Component Therapy', *The Journal of Pediatrics*, 1974; 84/2:165–172 [LIT.001.0141] at 0145

**21.143** Generally, however, in the early 1970s the increased risk of clinical illness was thought by clinicians to be insufficient to overbalance the advantages of the use of cryoprecipitate and concentrates in clinical treatment of haemophilia.<sup>132</sup> By 1974 many haemophilia patients receiving cryoprecipitate or Factor VIII concentrate had already become infected with the HBV but subsequent studies were to show that the vast majority of these individuals did not sustain long-term liver damage from that source of infection.

**21.144** However, the focus on Hepatitis B which had largely characterised the approach to assessing transfusion-associated transmission of infection until this time was about to shift. The Hepatitis A virus (HAV) was identified in 1973 and it became apparent that this was a water-borne, not blood-borne virus.<sup>133</sup> From 1974, research began to indicate that HBV accounted for a relatively small proportion of cases of post-transfusion hepatitis. On epidemiological and, subsequently, serological grounds, it became clear that HBV and, now, HAV could not account for the majority of cases of post-transfusion hepatitis as had been implied in earlier discussion. In 1974 Prince and others postulated the existence of an additional hepatitis virus or viruses, distinct from HAV and HBV.<sup>134</sup> The putative existence of non-A, non-B (NANB) Hepatitis was suggested by serological analysis published in 1975.<sup>135</sup>

### *1975 and growing understanding of risk of transmission*

**21.145** Developing knowledge of hepatitis thereafter is discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*. In Europe, Dr Mannucci and colleagues at Milan were among the leading commentators. In February 1975, they published a paper on the incidence of asymptomatic liver disease in haemophilia patients treated with cryoprecipitate, commercial factor concentrates, and, in the case of the older patients, fresh frozen plasma.<sup>136</sup> The authors reported asymptomatic liver abnormalities, and suggested that there was a need for long-term prospective evaluation of any possible relationship between these abnormalities in haemophilia patients and the development of overt hepatic dysfunction. It was a suggestion that the condition occurring in haemophilia patients (which came to be recognised as NANB Hepatitis) might be more than just a benign condition.

**21.146** Dr Garrott Allen, Stanford, a campaigner for volunteer donation in the USA, wrote to Dr Maycock on 6 January 1975. He commented on the ineffectiveness of screening for the HBV antigen and said that at least half of the cases of post-transfusion hepatitis were caused by an unknown agent other than Hepatitis A or B.<sup>137</sup> He remarked that this unknown agent still seemed to be more frequently encountered in the lower socio-economic groups of paid and prison donors. Dr Allen had raised an issue over the selection of donors that was to become significant in relation to the choice of therapeutic product as the period progressed.

<sup>132</sup> A powerful statement of the balancing of interests and the need to continue use of concentrates was set out in a letter by Kasper and Kipnis in *Journal of the American Medical Association*, 31 July 1972; 221/5:510 [LIT.001.0098]

<sup>137</sup> Dr Garrott Allen's letter of 6 January 1975 to Dr Maycock [SGH.004.6061]

**21.147** From 27 July to 1 August 1975, a symposium, organised by the World Federation of Hemophilia and the International Society of Blood Transfusion, took place in Helsinki. Topics included problems related to adverse effects of coagulation concentrates. The reports of proceedings at the symposium showed that concentrates were frequently associated with adverse effects which might include liver disease, thromboembolism and hepatitis. It was agreed, however, that the occurrence of these adverse effects, albeit of clinical relevance, did not justify withdrawal or reduction of the very effective and life-changing use of concentrates.<sup>138</sup> For a period this became the prevailing view among clinicians, and total consumption of Factor VIII concentrates continued to grow in the UK, as shown in Figure 21.1 above.

**21.148** In his evidence to the Inquiry Professor Forbes agreed that this was a view he shared around this time. Although aware of these risks, he advised that the risk of dying of bleeding was always much greater and that was what drove him and his colleagues to use these products despite the possible downside.<sup>139</sup> It appears, however, that there was now growing acceptance at international level that clinically relevant liver disease could be associated with the use of human blood products. The risk/benefit balance was about to become more problematical.

**21.149** There were two publications concerning concentrates and hepatitis in *The Lancet* of August 1975. The first, by Dr John Craske et al, reported an outbreak of jaundice associated with three out of four batches of a commercial brand of freeze-dried Factor VIII concentrate (Hemofil) at the Bournemouth Haemophilia Centre the previous year.<sup>140</sup> Dr Craske was then based at the Public Health Laboratory in Poole, Dorset.<sup>141</sup>

**21.150** Out of the 18 patients who had received the commercial concentrate nine became ill. Five patients had ‘non-B hepatitis’, two had Hepatitis B and two had both. In the introduction, Dr Craske commented on the huge improvement brought by concentrate treatment: concentrates were not associated with pyrexia and urticaria which occasionally occurred with cryoprecipitate, and they had made home treatment more practicable and major operations on haemophilia patients much easier.<sup>142</sup> But, on the authors’ findings, the risk of transfusion-associated hepatitis was greatly increased over single donor preparations. When blood for transfusion was prepared from commercial donations the risk increased the frequency of jaundice between three and nine times. In respect of concentrates, the article said:

There seems to be a pronounced increase in the risk of post-transfusion hepatitis when some batches of commercial freeze-dried factor-VIII concentrates are used. This must be balanced against the undoubted advantage that the freeze-dried product has over cryoprecipitate.<sup>143</sup>

**21.151** The article noted that the pool size might be critical in Factor VIII concentrates since transfusion hepatitis was a known hazard with large-pool products prepared from volunteer donors in the UK.

<sup>138</sup> Mannucci, ‘Side effects of antihemophilic concentrates’, *Scandinavian Journal of Haematology Supplement*, 1977; 30:1–5 [LIT.001.0150]

<sup>139</sup> Professor Forbes, Day 17, pages 46–47

<sup>140</sup> Craske et al, ‘An outbreak of hepatitis associated with intravenous injection of factor-VIII concentrate’, *The Lancet*, 2 August 1975; 2:221–223 [LIT.001.0360]

<sup>141</sup> Dr Craske’s fellow authors were from the Bournemouth Haemophilia Centre.

<sup>142</sup> Pyrexia is a fever and urticaria is a skin rash.

<sup>143</sup> Craske et al, ‘An outbreak of hepatitis associated with intravenous injection of factor-VIII concentrate’, *The Lancet*, 2 August 1975; 2:221–223 [LIT.001.0360] at 0362

**21.152** Measures to reduce the frequency of jaundice were suggested:

- The first recommendation was that commercial Factor VIII concentrates should be reserved for the treatment of life-threatening bleeds in all haemophilia patients and for covering major operations.
- The second recommendation was to reserve commercial concentrates for severely affected haemophilia patients '[S]ince they are more likely to be immune to hepatitis A and B'.<sup>144</sup>

**21.153** When giving evidence, Dr Winter commented that the first recommendation was not feasible in England at that time because there was not enough NHS concentrate to sustain the haemophilia population. In relation to the second recommendation he said that as the major hepatitis risk was transmission of Hepatitis C (NANB Hepatitis), the fact that the more severely treated patients might be immune to Hepatitis A or B would not actually be relevant.

**21.154** But Dr Winter thought that the paper generally stated exactly what would be expected: if haemophilia patients were given Factor VIII concentrate at that time, they would nearly all get abnormal liver function tests, yet only a minority of them would get clinical symptoms.<sup>145</sup>

**21.155** The second publication in *The Lancet* of August 1975, a letter by Dr Dane and Dr Cameron from the Middlesex Hospital Medical School in London, reported the testing of batches of commercial Factor VIII concentrate (including one of the batches referred to by Dr Craske in the first article) using the authors' own solid phase radioimmunoassay (RIA) test.<sup>146</sup> All three batches were found to be HBsAg positive (and therefore infectious for Hepatitis B). The authors believed that if donations were screened by RIA (a more sensitive test than employed by the manufacturers of the concentrates for routine screening) the final product would be much more likely to be safe. The letter from Drs Dane and Cameron did not refer to 'non B hepatitis' – the expression adopted in the Craske letter to distinguish unidentified cases from cases of HBsAg positivity.

**21.156** It was suggested to Dr Winter that the test used by Drs Dane and Cameron might be leading people in the wrong direction because it was creating a kind of reassurance: if there was better screening for Hepatitis B, the problem would be solved. He agreed, as Hepatitis C (HCV) was to become a much greater problem than Hepatitis B.<sup>147</sup>

**21.157** The papers by Drs Mannucci, Craske, Dane and Cameron in *The Lancet* of August 1975 marked a transition point in the information available to haemophilia clinicians that had a bearing on the selection of therapeutic products. While screening of donated blood for HBsAg had already substantially reduced the risk of post-transfusion Hepatitis B, the tests for screening each donor for HBsAg were, until the late 1970s, relatively insensitive. Many commercial Factor VIII concentrates contained contributions from thousands of donors, and were still infectious for Hepatitis B (as demonstrated by these studies). From 1975, as tests for Hepatitis B became increasingly sensitive, the realisation grew that one or more other infectious agents were responsible for a very high prevalence of liver blood test abnormalities in recipients of concentrates since evidence for past exposure

<sup>144</sup> Ibid [LIT.001.0360] at 0362

<sup>146</sup> Dane and Cameron, 'Factor-VIII concentrate and hepatitis', *The Lancet*, 16 August 1975 [LIT.001.0358]

<sup>147</sup> Dr Winter – Day 15, pages 99–100

to Hepatitis B was becoming less common. Biopsy results were to become an important factor in the debate.

**21.158** Awareness of NANB Hepatitis grew in the second half of the 1970s and particularly in association with blood product concentrates. Dr Winter said:

I think it was very well established by 1975, the group in Milan of Professor Mannucci had actually done liver biopsy studies which had demonstrated histological hepatitis in these patients as well, and it was for that reason by, you know, the mid 1970s that UKHCDO were starting to approach DOH with a view to persuading them to initiate moves toward self-sufficiency. It was the hepatitis argument that was obviously driving this initiative.<sup>148</sup>

**21.159** As noted above (paragraph 21.84), Dr Winter said that haemophilia patients expressed a very strong preference for concentrates. Compared with cryoprecipitate, concentrate offered very significant improvements in their quality of life. But they would also state that they did not want to have any concentrate of US origin. They wanted concentrate of British origin because of the perception that British donors were voluntary donors and were therefore acting out of altruistic motives whereas the commercial donors were donating for financial reasons and were more likely to be infected with viruses. This simplistic argument was very strong within the haemophilia community. Because of this perception, it took a lot of work in Dr Winter's clinic to persuade patients in some cases to continue to receive commercial concentrate.

**21.160** Dr Winter said there was a 'Tarzanoid' philosophy in relation to concentrates around this time: UK product good, US product bad.<sup>149</sup> The whole issue was about to move into the glare of media publicity.

### *'World in Action' television programmes*

**21.161** 'World in Action', a television programme in two parts shown in 1975, investigated the manufacture of blood products in the USA and the concept of self-sufficiency in the UK. A DVD of the programme was shown to the Inquiry and sent to several clinicians for their comments.<sup>150</sup>

**21.162** Part one, broadcast on 1 December 1975, featured three haemophilia patients whose lives had improved significantly since using commercial concentrates. One of these patients had experienced severe hepatitis, associated with Hemofil manufactured by Hyland, then a US drug company. Professor Arie Zuckerman, then recognised as an authority on hepatitis, was interviewed, as was Dr Craske. The documentary included footage of Hyland Donor Centres including centres in San Jose and downtown Los Angeles. The 'World in Action' team found that Hyland's paid donors included alcoholics and down-and-outs. It was suggested that, because of their lifestyles, many of these donors from 'Skid Row' areas were likely to be carriers of hepatitis viruses.

**21.163** Dr J Garrott Allen, the campaigner against the paid donor system in the USA already mentioned, was interviewed on the programme and he said that a number of studies carried out in the previous decade had indicated that the risk of hepatitis was 60–70 times greater from paid donors than from a volunteer source such as friends and relatives.

<sup>148</sup> Ibid pages 104–105. Dr Winter was wrong in suggesting that Mannucci and colleagues had done liver biopsy studies by 1975. Mannucci's first liver biopsy study came out in 1978: Mannucci et al, 'A clinicopathological study of liver disease in haemophiliacs', *Journal of Clinical Pathology*, 1978; 31: 779–783 [LIT.001.1624] at 1627–28

<sup>149</sup> Dr Winter – Day 15, pages 107–108

<sup>150</sup> For a transcript of the programme see [PEN.013.1400]

**21.164** Dr Richard Wilbur, the senior Vice President for Medical Affairs at Baxter Laboratories (then owner of Hyland), was also interviewed. Dr Wilbur's reaction to hepatitis infection in England following use of Hemofil was that the reported cases occurred from earlier batches made before their new techniques for screening donors for hepatitis were in place.<sup>151</sup> He considered that the risk-benefit ratio of taking Factor VIII concentrate compared with 'this relatively mild' disease was a good one for the patient.<sup>152</sup> When asked about the type of donors who sold their plasma to Hyland, Dr Wilbur said:

[W]e would prefer that all of the plasma were available from better sources and we do not deliberately seek out as a source of plasma the unfortunate people in the country. As I said before, we would vastly prefer to have it from voluntary donors just as everyone would like to have blood transfusions from voluntary donors.<sup>153</sup>

**21.165** This part of the programme ended with the investigation team commenting that Hemofil carried a high risk for three reasons: the use of paid donors, its production from large plasma pools, and the inadequacy of hepatitis tests.<sup>154</sup>

**29.166** Part two, broadcast on 8 December 1975 focused more strongly on the supply of concentrates in the UK. Patients and the Haemophilia Society both indicated their preference for UK material. Dr Maycock, then senior advisor to the Department of Health on blood transfusion policy, was interviewed, as was Mr John Watt, of the PFC.<sup>155</sup>

**29.167** Dr Maycock was asked about the decision to import concentrates in 1973, given the known hepatitis risk of paid donors. It was suggested that the Department of Health had been somewhat complacent about these risks. Dr Maycock did not agree: he thought the quality of the material was controlled, both in the UK and the USA. His view was not shared by Professor Zuckerman who believed that it was well recognised that the commercial donor carried a considerably greater risk of transmitting hepatitis than the volunteer donor. But it was reported that British-made concentrates were not entirely free of risk either. Since the previous year, Professor Zuckerman had also detected a surprising number of infected batches of English concentrate.

**29.168** Dr Maycock said he hoped that self-sufficiency would be achieved by mid-1977. He rejected the suggestion that there might not be sufficient production capacity or enough donors. He stressed that there was certainly no lack of donors.

**29.169** Mr Watt told the presenter that the new plant in Edinburgh, the PFC, should be able at capacity, to produce more than the need for all plasma fractions for Scotland by the spring of the following year (1976). After that it would depend on government policy. Mr Watt agreed with the presenter that making concentrates in the UK should be very much cheaper than importing foreign concentrates. As well as cost, Mr Watt talked about the ethics of importing Factor VIII concentrates from impoverished countries. He said:

I know of one Middle Eastern country where a haemophiliac patient may travel 300 miles and wait for several days outside the clinic looking for treatment and

---

<sup>151</sup> This would have been a reference to improved screening of donor blood for HBsAg.

<sup>152</sup> World in Action transcript [PEN.013.1400] at 1411

<sup>153</sup> Ibid [PEN.013.1400] at 1413

<sup>154</sup> Ibid

<sup>155</sup> John Watt was introduced in the programme as Scientific Director of the Scottish Blood Transfusion Association but at this time he was the Scientific Director of the PFC, Liberton.

it's not because the clinic doesn't want to take them in, it's because they don't have enough beds and they don't have enough material. The Factor VIII isn't there. It's all gone to the more affluent parts of the world.<sup>156</sup>

**29.170** Dr David Owen, then Secretary of State for Health, also appeared on the programme and was asked how long it would take before Britain could stop being dependent on imported concentrate. He replied: '[A]s fast as buildings can be set up and equipment purchased .... We've brought it down to two years and maybe we can improve even on that'.<sup>157</sup> He agreed with the journalist interviewing him that paid donors were a greater health risk than volunteer British donors. But he said there was always some risk from any use of blood from donors.

**29.171** In relation to the world trade in plasma Dr Owen said: 'I think there's a very strong moral case for once you are self-sufficient, ensuring that you use only your own national sources and freeing up those resources in other nations for their needs'.<sup>158</sup>

**29.172** Dr Winter viewed the documentary and provided the Inquiry with a statement in which he commented:

The opening scenes, with various British teenage haemophiliacs and their families, are especially important since they underscore the very great improvement in quality of life afforded by the new concentrates, as compared with the use of cryoprecipitate, which was clumsy, time consuming, associated with side effects and in particular had to be administered in hospital.<sup>159</sup>

The programme had looked at the case of one boy who, before home therapy, had made 98 visits to hospital in one year and had three months off school.<sup>160</sup>

**29.173** Dr Winter noted in his statement that the programme set out visually what was already clear at the time: blood products derived from commercial donations were significantly more likely to be associated with viral infections.<sup>161</sup> Near the beginning of the programme it was revealed that paid donors had six to 13 times the risk of having hepatitis.

**29.174** The programme showed people waiting to give blood with bottles of alcohol sticking out of their pockets, but Dr Winter advised the Inquiry that the major consideration to prevent a batch being infected was the viral status of a donor: whether the donor was underweight or drank alcohol would be of less significance to the risk of virus infection of the donation.<sup>162</sup>

**29.175** Dr Winter said that it was his understanding that the pool size in commercial manufacture would be at least 20,000 and sometimes higher by the mid-1970s. Haemophilia doctors thought at the time that if the patient received Factor VIII concentrate in the 1970s, particularly from US donor plasma, it was inevitable that he was getting a number of different hepatitis infections.<sup>163</sup>

<sup>162</sup> Dr Winter – Day 15, page 85

<sup>163</sup> Ibid pages 82–83

**29.176** In Dr Winter's opinion, Professor Zuckerman and the others were really talking about Hepatitis B in the programme. In the mid-1970s after two or three years of concentrate use, many patients with haemophilia were displaying blood tests suggestive of a hepatitis-like pattern in their liver function blood tests. They were by and large very well. Maybe 5% or perhaps higher had circulating levels of Hepatitis B and about 20% could be shown to have antibodies against Hepatitis B; a small percentage could be demonstrated to have Hepatitis A but for the majority of these other patients, who clearly had a hepatitis-like picture on their liver function blood tests, all the standard Hepatitis A and B markers were negative. So it was for this reason that haemophilia doctors came to think that there was a third type of hepatitis which was called 'non-A, non-B Hepatitis'.

**29.177** Dr Winter advised that a patient who got NANB Hepatitis could become clinically unwell, but that was not necessarily a very common event and not as common as clinical illness in Hepatitis A or B. In case of infection with either of those viruses, the patient normally felt thoroughly unwell at the time of the infection. NANB Hepatitis was more likely to get into the blood stream and inflame the liver. The focus for discussion in the documentary should have been NANB Hepatitis, because it was (in retrospect) by far the most relevant type of hepatitis for these patients.<sup>164</sup>

**29.178** It has to be noted that while, in retrospect, Dr Winter was correct in his comment about the incidence of NANB Hepatitis it was only in 1975 that the first suggestions of the existence of NANB Hepatitis (first postulated in 1974) were beginning to be accepted. And, beyond the observation that many individuals with haemophilia were beginning to have persistent, usually mild, blood test abnormalities, nothing was known about NANB Hepatitis/HCV-related chronic liver disease, still less about its impact on infected haemophilia patients 10 or more years later. The documentary could not have dealt with NANBH/HCV at the time: it was really concerned with Hepatitis B.

**29.179** In the programme Professor Zuckerman said:

[H]epatitis, or jaundice, is a particularly interesting infection because the severity of the illness ranges from a very mild form of infection, perhaps with trivial symptoms, to an attack of jaundice with quite a lot of disability which may last for some weeks or perhaps even months, and it is associated with a significant death rate. In addition, in a number of cases it may progress to chronic liver damage and may end up in a condition such as chronic active hepatitis or cirrhosis of the liver.<sup>165</sup>

**29.180** A professor of medicine at the University of Southern California, Dr Mosley, was asked in the programme to quantify the risk of getting hepatitis from a clotting factor concentrate and his response was: 'probably 100 per cent if the individual is susceptible'.<sup>166</sup> Dr Winter suggested that 'susceptible' in this context probably meant that the individual did not already have antibodies to HBV.<sup>167</sup>

**29.181** One of the committee members from the Haemophilia Society interviewed in the programme said that people with haemophilia were not too bothered about where the blood came from as long as they had blood concentrate to keep them going, and in some

---

<sup>164</sup> Ibid pages 86–87

<sup>165</sup> World in Action transcript [PEN.013.1400] at 1402

<sup>166</sup> Ibid [PEN.013.1400] at 1408

<sup>167</sup> Dr Winter – Day 15, pages 91–92

cases to keep them alive; of course they would prefer that blood was donated voluntarily and not from people who were undernourished and alcoholic.<sup>168</sup> Dr Winter recognised that sentiment. In his centre the supply of NHS concentrate was very limited and at least 90% of the concentrate was commercial in origin. This was due to the capacity of the plant at Elstree to produce the concentrate, and a policy of preferential supply to certain hospitals.<sup>169</sup>

**29.182** One of the patients featured on the programme who had contracted hepatitis while using Hemofil talked about how he was vomiting really badly and wondered whether it was worth using the concentrate. Two days later, he had a bleed in his elbow and said he had no hesitation in going to the fridge and injecting the Hemofil because he knew it would stop the bleeding and the pain from the bleed was going to be so much worse than any of the pain he had suffered with hepatitis.<sup>170</sup>

**29.183** Dr Winter was not surprised by what this patient had said and commented:

That's a mirror of, as I have been trying to reflect in my comments, the quite extraordinary change of quality of life for these people whose existence had really been pretty miserable, regular bleeding into joints and muscles, poor schooling, lifelong pain, no sport, limited ability to get jobs because of poor education, and suddenly there was this white powder they could give at home and it had an enormous difference. So for all these reasons, when faced with this variable data with variable opinions by doctors, their view was 'Well, we are extremely reluctant to consider not using this product any more because of the quality of life it has given us'.<sup>171</sup>

**29.184** Professor Forbes said that he had not watched the programme when it was shown in 1975 but had seen it twice since then. He remembered when it was broadcast that it was the talk of the haemophilia part of the hospital. He thought that there was a gasp of disbelief when they showed the types of donors that were being used to give plasma in commercial centres. Professor Forbes was appalled when he watched the programme recently; there was no monitoring at all of these paid donors and even if they were asked questions, they denied they had any problems whatsoever but clearly they did have. He thought it was incredible to see the donors drinking alcohol immediately before they gave blood.<sup>172</sup>

**29.185** Although Professor Forbes could not remember any specific details in relation to practitioners' reactions to the programme, he stated that people felt this was not the way to go. Commercial concentrates of all kinds, probably not just Hemofil (featured in the programme) but the other ones too, were all 'tarred with the same brush'.<sup>173</sup>

**29.186** Having watched the 'World in Action' programme, Professor Cash wrote to *The Lancet* at the beginning of January 1976 stating:

There is no doubt that the import into the United Kingdom of factor VIII concentrates derived from external sources, however well screened for hepatitis viruses, represents an unequivocal pathway by which the level of a potentially

<sup>168</sup> World in Action transcript [PEN.013.1400] at 1418

<sup>170</sup> World in Action transcript [PEN.013.1400] at 1415

<sup>171</sup> Dr Winter – Day 15, pages 94–95

<sup>172</sup> Professor Forbes – Day 17, pages 30–31

<sup>173</sup> Ibid page 32

lethal virus into the *whole* community is being deliberately increased. Although the absolute magnitude of this problem was exaggerated and over-dramatised by the television programmes, nobody with direct or indirect responsibilities for this phenomenon would wish to belittle the serious nature of the moral and practical dilemmas which face us all.

Perhaps the most misleading feature of the second television programme was the impression given that the recent and specific injection of £500,000 by the DHSS into the blood transfusion services will have worked its way through by mid-1977 and by that time the necessity to purchase further supplies of factor VIII concentrates will be eliminated. Our own experience indicates that this will not occur, not least because the present NHS production target for factor VIII concentrates is too low.<sup>174</sup>

**29.187** Professor Cash was asked about the letter when he appeared at the Inquiry and it was suggested to him that he had been something of a prophet, in commenting on risk of a 'potentially lethal virus' in the early 1980s. His response was:

[B]ut I wouldn't see myself as some prophet, a prophet of doom ... in 1969 I did my own World in Action. I had a WHO travel fellowship and spent three and a half months in the States looking very carefully at all aspects of their transfusion service, made a lot of hugely important friends over there that were immensely important in the later years. And one of the things I did when I was in California was to go into the Cutter – it was Cutter, not Hyland – skid row area, and this is San Francisco, as I recall, and – I mean, I thought the film was pretty gentle on that. What I saw was obscene. It was just obscene.<sup>175</sup>

**29.188** Professor Cash went on to say that he thought the film had exaggerated the situation because not all plasma that was used in commercial concentrates was coming from 'Skid Row'. There were some companies who claimed (and Professor Cash said he believed them at this time) that they did not use these sorts of donors at all but used 'university campus people'. He pointed out that PCR Hepatitis C studies were carried out many years later on old batches of commercial concentrate and some of them were negative.<sup>176</sup>

**29.189** Dr Boulton who was working as a Director of the Liverpool Haemophilia Centre at this time told the Inquiry that he did not see the programme but he remembered conversations after it was broadcast.<sup>177</sup> He felt at the time that the programme had exaggerated the problem but he admitted that he was then a young and inexperienced doctor. A year or so before the programme, in 1973 or 1974, Dr Boulton was working at the London Hospital and had seen a haemophilic patient who needed Factor VIII over Christmas for a fairly major dental problem. There was not enough NHS cryoprecipitate or NHS Factor VIII in stock to cover the surgery safely so Dr Boulton ordered in a small amount of commercial Factor VIII and this mild haemophilic man in his 50s received some. The man got both Hepatitis B and NANB Hepatitis. Dr Boulton said that he had a rather rude awakening into the dangers of hepatitis from commercial (in this case US) Factor VIII.

<sup>174</sup> Cash, 'Commercial and NHS factor VIII concentrates', *The Lancet*, 24 January 1976; 221 [LIT.001.0245]

<sup>175</sup> Professor Cash – Day 25, page 75

<sup>176</sup> *Ibid* pages 75–76

<sup>177</sup> Dr Boulton – Day 24, pages 9–11; Dr Boulton took up the post of Consultant and Honorary Lecturer in Haematology and Blood Transfusion, BTS, Edinburgh in 1980; he became Deputy Director in 1982.

**29.190** Dr Boulton said that when he was working in Liverpool (after October 1975), commercial Factor VIII was bought from Austria not the USA. There was clearly a concern then that US products were to be avoided and he believes that this was a legitimate or at least understandable reaction to his experience of treating and giving a patient NANB Hepatitis. Dr Boulton was asked if the plasma used for the Austrian commercial product was Austrian. He replied that it was quite possible that some of the plasma came from the USA but he did not know that at the time; he was under the impression, and had been told by Immuno's director, that the material was Austrian in origin. But it was clearly from paid donors.<sup>178</sup>

### ***Commercial concentrate production in the mid- to late-1970s***

**29.191** As the 'World in Action' programme revealed, one of the first concentrates used in the UK was Hemofil, manufactured by Hyland. It was not the only product on the market. By the late 1970s four major companies controlled most of the world's plasma. Based in the USA they were:

- Cutter Laboratories of Berkeley, California.
- Alpha Therapeutic Corporation of Los Angeles.
- Armour Laboratories of Chicago.
- Hyland in a suburb of Los Angeles.

**29.192** International pressure against exploiting developing countries had restricted the supply of plasma from 'the Third World plasma mills',<sup>179</sup> and foreign firms were keen to have access to the lucrative American drug market. By the end of the 1970s only Hyland remained in American hands; it belonged to Baxter Travenol Laboratories, based in Chicago. Alpha Therapeutic had been bought by a Japanese company (Dr Naito's Green Cross Company); the German pharmaceutical company, Bayer AG, had taken over Cutter Laboratories; and Armour was in the hands of the French multinational Rhone-Poulenc.<sup>180</sup>

*Increasing evidence of the risk of hepatitis in the late 1970s*

**29.194** Notwithstanding Professor Cash's reservations about their accuracy, the 'World in Action' programmes could have left no interested observer in doubt that at least some clinical specialists believed that commercial factor products carried an unacceptable risk of transmitting hepatitis virus infection in comparison with the NHS products in manufacture at the time. The accounts of reactions among hospital staff, for example by Professor Forbes, indicate that these were extreme. Some experts, in addition to Professor Cash, could draw on personal observation and experience.

**29.195** Dr McClelland was appointed to the SNBTS in 1977. Sometime after his appointment, he visited the Cutter Company in San Francisco. In his statement provided to the Inquiry, he wrote:

I also remember very clearly an experience that has coloured my thinking about the use of blood from commercial donors throughout my career, and I cannot think of any reason why this would not have influenced my own views about commercial Factor VIII during the early 1980s. Shortly after my appointment to the SNBTS in 1977 (I do not have a record of the dates) I visited the Cutter Company in San Francisco. During this trip I visited their Oakland plasma centre. I have a very clear recollection of being amazed to find that there were no donors in the centre and that I asked one of the two staff in evidence why the centre was empty. I recall her response, which was that this was typical for that day of the week, because it was the day for collection of social security cheques. I also recall that I took away a copy of a notice displayed in the centre [reproduced at Figure 21.7 below]. This stated the fees for a plasma collection – \$US 16.

This visit left me in no doubt that even in this relatively favoured part of the USA, the company depended very heavily on the provision of plasma by people of low income. One implication of this that was clear to me at that time was that plasma was being collected from individuals who might be dependent on the payments from the plasma centre and who would therefore have an incentive to conceal any aspects of their health that might make them unsuitable as donors.<sup>182</sup>

<sup>182</sup> Dr McClelland's statement on the use of blood product concentrates [PEN.015.0307]. See also Dr McClelland – Day 21, pages 88–91

Figure 21.7

**21.196** Dr McClelland referred to the 'World in Action' programme when giving evidence about haemophilia patients keeping abreast of developments in therapy. He was very impressed with the common sense knowledge that a lot of the patients and some of the parents featured on the programme expressed about the infection risks and the safety and effectiveness of the products.<sup>183</sup>

**21.197** Dr McClelland told the Inquiry that when he was on-call for the BTS, professionals who happened to be haemophilia patients would visit and they would very often have their own specific personal views about which product they had chosen to be treated with.<sup>184</sup> He said:

There were some individuals who would only accept to be treated with cryoprecipitate, even accepting all the inconvenience. There were some who would not accept treatment with imported Factor VIII. There are some who had a very strong preference for particular products and it would be quite wrong, I think, to say that these were idiosyncratic preferences. These patients almost certainly had extremely good reasons, which they could probably explain very articulately in many cases, why they chose a particular approach to their own treatment, and my recollection is that that was evident among some, not all, but some of the haemophilia patients early on in my career.<sup>185</sup>

<sup>183</sup> Dr McClelland – Day 21, pages 161–162

<sup>184</sup> Dr McClelland started working for the BTS in Edinburgh in 1977.

<sup>185</sup> Dr McClelland – Day 21, pages 159–160

**21.198** When asked if the patients' expertise related to their perception of the effectiveness of the different products, Dr McClelland replied:

In the broad sense – well it depends how you define 'effectiveness'. Strictly speaking, I would define clinical effectiveness as essentially describing the balance of benefit and disbenefit. So safety is actually, in that sense, part of effectiveness, but it may be easier to separate them out and say were they concerned about the safety, which, if you think might be: what will this do to me in the long term? Will I get something nasty in two, five, ten years' time? As opposed to: will this stop my bleed and control my pain now, better than other products?

And of course, the third factor that to some patients mattered a lot, is inconvenience. Will it take me an hour fiddling around with syringes and needles and jars of salt water and other things to get my dose, or can I go to the fridge, take it out, stick a syringe in and that's it? All those factors and many others would have influenced their choices.<sup>186</sup>

**21.199** In the Inquiry's view Dr McClelland's impressions reflected a realistic assessment of the position. In the meantime, more structured investigations continued.

**21.200** At the meeting of the UKHCDO held on 13 January 1977 (referred to above), Dr Craske presented a report on his continuing study of hepatitis in haemophilia patients treated with Hemofil.<sup>187</sup> Three hundred and seventy one patients had been followed up. One had died with cause of death possibly attributable to Hepatitis B. Dr Craske proposed an extension of his study over two years. He suggested that:

This continued study would include a follow up of patients who had had Hemofil associated hepatitis to study the incidence of chronic sequelae, and a comparison of jaundice associated with NHS Factor VIII and commercial products.<sup>188</sup>

**21.201** The discussion reflects a degree of scepticism among the haemophilia clinicians. As minuted:

Prof Stewart said that jaundice would always occur and there were difficulties in specific identification of the causal agents. Dr Dane [a virologist] said there were problems with the sub-typing. This was possible with samples from patients but was difficult with the concentrates because of the very small amounts of virus present in the samples. Tests for HBsAg could not pick up trace amounts of antigen. Hepatitis B was uncommon in the general population in patients under 14 years of age.<sup>189</sup>

**21.202** Dr Craske was challenged on how he distinguished between Hepatitis B and non-B types. At the same meeting, Dr Biggs reported data returned from haemophilia centres on the incidence of jaundice. There was no action proposed in response to Dr Craske's study, which continued in any event, and his Working Party reported in due course.

**21.203** The meeting discussed the supply of Factor VIII. At earlier meetings of the Reference Centre Directors it had been established that the BTS could supply sufficient plasma for fractionation to provide a minimum of 40 million units of Factor VIII per year. However there was a hold-up in the expansion of the fractionation process in the UK.

**21.204** Dr Macdonald (Glasgow Royal Infirmary) talked about supplies of Factor VIII concentrate in the west of Scotland. He said that the PFC at Liberton had the capacity to make 60 million units of Factor VIII per year but to reach this figure, the centre would need about £25,000 for new equipment and extra running costs including payment for staff to operate a 24-hour shift system of working. He advised that, in 1976, 14% of all Factor VIII used in the west of Scotland was commercial and 46% of Factor VIII used was freeze-dried NHS intermediate potency concentrate (from the PFC at Liberton).<sup>190</sup>

**21.205** The meeting was informed of a joint plan by the DHSS and the SHHD to divert plasma from south of the border to Liberton for fractionation and return to England and Wales once the Liberton PFC was fully operational: it was not known at this time when that would be.<sup>191</sup>

**21.206** Once more, it was Professor Mannucci and his colleagues who moved the debate forward in an editorial published in 1977 on the work of the Helsinki Symposium, 27 July–1 August 1975, as noted above at paragraph 21.147.<sup>192</sup> The work of this team, as published in 1975, on the natural history of NANB Hepatitis is discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975–1985*, at paragraph 15.37. The 1977 editorial contained an important analysis of papers discussing the known side-effects of the use of concentrates and an assessment of their significance. It pointed to the advent of home therapy as a factor that might be significant, especially in the light of the observations by Jones et al which emphasised the possibility that complications might develop far from the control of specialised centres. But the editorial did not expand on it. The material part of the paper carried forward the group's analysis of the consequence for haemophilia patients of long-term exposure to 'the agent(s) implicated in *post-transfusion hepatitis*'. They noted that the incidence of clinical illness associated with jaundice was surprisingly low in people with haemophilia. But they commented:

[T]he research of Hasiba et al and Yannitsiotis et al suggests that the observed abnormalities are likely to be related to the frequent and repeated exposure to the agent contaminating the blood derivatives. The observation of Hasiba et al that abnormal liver function was more frequent in patients treated with commercial concentrates than in those treated with blood-bank cryoprecipitate is rewarding, because it clearly shows a way in which prevention can be attempted.<sup>193</sup>

**21.207** The position remained, however, that the clinical and prognostic significance of the observed anomalies in patients was unknown, and that the great majority of the patients were asymptomatic and free of physical signs of liver involvement. It was concluded that until an answer could be provided by long-term prospective evaluation, it appeared unjustified to withdraw or reduce the very effective and life-changing use of concentrates. The same view was emphasised in the discussion:

<sup>190</sup> Ibid [SNB.001.7117] at 7132

<sup>191</sup> In the end this plan did not proceed. See Chapter 19, *Production of Blood Products – Facilities*.

<sup>192</sup> Mannucci, 'Side-effects of antihemophilic concentrates', *Scandinavian Journal of Haematology*, 1977; 30:1–5 [LIT.001.0150]

<sup>193</sup> Ibid [LIT.001.0150] at 0151

[A]nti-hemophilic concentrates are frequently associated with side effects which may be of clinical relevance. However, they do not justify withdrawal or limitation of replacement therapy, which would be accompanied by a consistent deterioration of the present pattern of life of hemophiliacs.<sup>194</sup>

**21.208** In April 1977, Mannucci and colleagues reported on the use of 1-Deamino-8-D-Arginine Vasopressin (DDAVP) to promote Factor VIII properties in patients with moderate and mild haemophilia and von Willebrand's disease undergoing surgery, without use of plasma concentrates.<sup>195</sup> In his review of this period in the paper 'AIDS, hepatitis and hemophilia in the 1980s: memoirs from an insider', Professor Mannucci stated that the advantages of DDAVP in reducing the risk of blood-borne infection in mild haemophilia were immediately appreciated in Italy, where the early use of DDAVP led to a significantly lower rate of infection in Italian patients with mild Haemophilia A when compared to patients with mild Haemophilia B which was unresponsive to DDAVP.<sup>196</sup>

**21.209** SNBTS researchers were aware that there was a rise in Factor VIII activity after infusion of DDAVP. The effect had first been described by SNBTS staff using peptides synthesised in Czechoslovakia.<sup>197</sup> However, there was reluctance to trial the preparation in UK patients, and the intelligence was shared with Italian colleagues who published the 1977 paper referred to. In the circumstances, Mannucci's confirmation of the effectiveness of DDAVP might have been expected to lead to increased use of DDAVP in the UK and Scotland in particular. There was no reference to DDAVP therapy in the minutes of the UKHCDO for 1977, after Mannucci had published, as bearing on the treatment of haemophilia patients. Scotland was well represented at the meetings, but the representatives do not appear to have raised the subject.

**21.210** Towards the end of the 1970s there was an increasing awareness that use of concentrates carried a high risk of hepatitis, particularly in previously untreated patients or in patients who had been treated infrequently.

**21.211** Papers in late 1977 and 1978 by Lesesne,<sup>198</sup> Spero,<sup>199</sup> Mannucci<sup>200</sup> and Preston added significantly to the debate about the relationship between concentrate use and hepatitis. All of these papers were based on the results of liver biopsies which was new evidence. Developing thought is discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975–1985*.

**21.212** What was to prove in time a significant development in the UK was reported on 16 September 1978. Preston and colleagues (Sheffield) published 'Percutaneous liver biopsy and chronic liver disease in haemophiliacs'.<sup>201</sup> Having dealt with HBV, the paper commented:

<sup>194</sup> Ibid [LIT.001.0150] at 0153

<sup>201</sup> Preston et al, 'Percutaneous liver biopsy and chronic liver disease in haemophiliacs', *The Lancet*, 16 September 1978; 592–594 [LIT.001.0387]

In addition, non-A, non-B hepatitis may well be an important factor and observations in four of our eight patients support this possibility.

**21.213** Among other conclusions, the paper stated:

A wide spectrum of chronic liver disease was demonstrated, including chronic aggressive hepatitis and cirrhosis. The liver pathology bore no relation to clinical history or to biochemical findings .... The high incidence of chronic liver disease seems to be a recent development and is probably related to factor-concentrate replacement therapy.

**21.214** The immediate impact of this research in the UK, and in particular of the Preston publication, was not great. At the time, Sheffield was not a noted centre of excellence in research in this field, and the significance of the findings of Preston et al was not appreciated. Lesesne, Spero and Manucci had not recommended an immediate change in therapeutic practice. Nor had Preston. As Table 21.1 in the Appendix to this chapter shows, growth in concentrate usage accelerated after 1978.

**21.215** After the initial outbreak of hepatitis following infusion of Hemofil Factor VIII concentrate in 1975, Dr Craske and his colleagues had been charged by the Haemophilia Centre Directors with forming a working party to survey more closely the overall incidence of hepatitis following the use of Hemofil and all other Factor VIII products used in the UK. In addition, the survey was originally aimed at analysing the different types of hepatitis that occurred, whether due to Hepatitis B virus or non-B (subsequently non-A non-B) virus or viruses. It was also to begin to assess the possibility that some attacks of hepatitis could lead to chronic liver disease.

**21.216** Although the survey was far from perfect, partly because knowledge of the putative NANB Hepatitis virus became progressively more definite during the two years of the survey period, the results and the conclusions drawn by Dr Craske and his colleagues were important. The full results of the incidence of hepatitis following use of all Factor VIII products were disclosed to the Haemophilia Centre Directors in August 1978. The report was published in November 1978.<sup>202</sup>

**21.217** There were returns from 24 haemophilia centres. Overall 207 overt episodes of hepatitis (symptoms of hepatitis and abnormal liver test results) were reported. All Factor VIII products were implicated. One hundred and thirty five cases (65.2% of the total) were thought to be non-B and 72 (34.8% of the total) were thought to be Hepatitis B related. Hepatitis was again defined by symptoms. There was no systematic measurement of liver function tests carried out on all recipients. From these studies Craske and colleagues concluded that there were probably two different organisms responsible for 'non-B' Hepatitis, based upon incubation times and the occurrence of apparent multiple attacks in some patients.

**21.218** Although no evidence was produced by the survey as to the likelihood of development of chronic liver disease following an acute attack, the report also referred to a visit by Dr Craske to Dr Roberts and his colleagues at the Department of Medicine at the University of North Carolina. One hundred liver biopsies had been carried out on patients there who had been treated for up to 10 years with Factor VIII concentrates. Chronically elevated serum transaminases were recorded, and nearly 50% had histological changes compatible with cirrhosis, chronic active or chronic persistent hepatitis. The report noted:

<sup>202</sup> Report of the Haemophilia Centre Directors' Hepatitis Working Party – 1978 [SNB.001.7192]

There is controversy as to whether these changes are the sequel to acute virus hepatitis, or are due to some other cause, but Dr Roberts and many other physicians are of opinion that virus hepatitis is the main factor. The elucidation of this problem, therefore, remains the most urgent one from the patient's point of view.<sup>203</sup>

**21.219** Unlike post-transfusion hepatitis, in respect of which different views were held at this time as between the USA and the UK/Europe, in the case of chronic hepatitis in haemophilia patients there was a consensus among US and European investigators. Despite cautious reports, the general view remained in 1978 that the disease in people with haemophilia, while inevitable in a high proportion of patients, was, to a great extent, probably benign. This view was to change very gradually over the next 10 years, as discussed later.

**21.220** The possibility that further work might show whether more than one agent was involved, canvassed by Dr Craske and his colleagues, was taken up in a letter to *The Lancet* of 11 November 1978: 'Evidence for existence of at least two types of Factor-VIII-associated non-B transfusion hepatitis'.<sup>204</sup> Comparison of observations following infusion of a number of commercial products suggested that at least two agents might be involved. The finding was said to emphasise the need for further work to attempt to isolate the infective agents involved.

**21.221** Discussions about the risk of transmission of hepatitis continued throughout 1979. Only now, more attention came to be focused on NANB Hepatitis. The issue was raised in a meeting at the MRC on 12 February 1979.<sup>205</sup> At this meeting it was decided that a major UK study of post-transfusion hepatitis should not be supported by the MRC.<sup>206</sup>

**21.222** The decision that a survey of post-transfusion hepatitis was not warranted was to have longer-term consequences. In the US studies had contributed to the understanding that the prevalence of infection in a given community was an important factor in assessing risk. Lack of similar research contributed to the perpetuation of error about the prevalence of infection in the UK.

**21.223** On 10 March 1979, Wyke and others (including Zuckerman), published 'Transmission of NANBH to chimpanzees by Factor IX concentrates after fatal complications in patients with chronic liver disease'.<sup>207</sup> Seventeen patients at the liver unit, King's College Hospital, received concentrate from four different batches of commercial and non-commercial concentrate. Six cases of NANB Hepatitis resulted. The chimpanzees were infused with batches of Factor IX (from commercial and non-commercial sources) which were associated with the transmission of NANB Hepatitis to the infected patients, and with blood from implicated donors. All the chimpanzees had developed hepatitis. It was suggested that, until there was a screening test for the NANB Hepatitis agent, concentrates should be restricted:

<sup>203</sup> Ibid [SNB.001.7192] at 7197

<sup>204</sup> Craske et al, 'Evidence for existence of at least two types of Factor-VIII-associated non-B transfusion hepatitis' *The Lancet*, 1978; 2:1051-52 [LIT.001.0392]

<sup>205</sup> Minutes of meeting, 12 February 1979 [DHF.002.4842]. See Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*.

<sup>206</sup> Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975–1985*.

<sup>207</sup> Wyke et al, 'Transmission of NANBH to chimpanzees by Factor IX concentrates after fatal complications in patients with chronic liver disease', *The Lancet*, 10 March 1979; 520-524 [LIT.001.0378]

Until blood-donors can be screened for the non-A non-B hepatitis agent, it would seem wise to restrict the use of both commercial and non-commercial concentrates to life-threatening situations. In particular, their use in patients with chronic liver disease should be avoided, as the risk of a serious illness resulting appears to be increased.

**21.224** That advice was not followed. The Haemophilia Reference Centre Directors met again on 15 October 1979.<sup>208</sup> The Hepatitis Working Party had produced a report in relation to liver disease in patients with haemophilia which had been circulated to all the Reference Centre Directors in advance of the meeting. One hundred and seventy nine patients with severe Haemophilia A were studied. Following physical examination of the patients and analysis of their liver function tests, results showed that in spite of multiple transfusions and very large numbers of grossly abnormal liver function tests, very few patients showed any stigmata of chronic liver disease. Patients treated with different types of Factor VIII (NHS and commercial) showed no significant difference in either their liver function tests or viral hepatitis markers.<sup>209</sup> There was discussion regarding the details in the report but this was not recorded in the minutes. Dr Craske invited the Centre Directors to let him have their comments on a draft form (Form C3) asking for information on patients thought to have developed chronic hepatitis.

**21.225** At the 10th meeting of the UKHCDO on 20–21 November 1979, an updated version of Dr Craske's Hepatitis Working Party report was presented.<sup>210</sup> There was much discussion on the contents of the report including (apparently for the first time at a UKHCDO meeting) the prevalence of chronic hepatitis in haemophilia patients. Age appeared to be a very relevant factor. The average attack rate of hepatitis in patients over 40 was six times that for those aged up to 40. Dr Craske commented that most patients thought to have developed chronic hepatitis had not previously had an overt attack of hepatitis. Professor Stewart of the Middlesex Hospital suggested that samples of liver should be obtained from all haemophilia patients who went to post-mortem. Causes of hepatitis were said to be uncertain: the meeting was reminded to keep an open mind. The directors were again asked to report cases of chronic hepatitis by completing the working party's approved version of the new Form C3.<sup>211</sup> Dr Craske stated that there were two types of non-A, non-B Hepatitis, a more confident assertion than previously. In a wide-ranging discussion over two days, including a scientific session, there was, so far as recorded, no discussion of change in practice relating to the prescription of Factor VIII.

**21.226** On 30 April 1980, the Council of Europe, Committee of Ministers, made a number of recommendations including No R(80) 'concerning blood products for the treatment of haemophiliacs'.<sup>212</sup> The recommendations stated that Member States should pursue the goal of self-sufficiency in anti-haemophilia products and in blood plasma for their preparation. The appendix set out recommendations the Council considered desirable for each Member State including:

[T]o give the necessary information to all concerned in haemophilia therapy regarding the problems arising from the procurement and rational use of

products; it must be realised that a balance should be achieved between the available resources and the justified needs of haemophiliacs.<sup>213</sup>

**21.227** On 30 September 1980, the UK Haemophilia Centre Directors met in Glasgow.<sup>214</sup> Dr Craske presented the report of the Hepatitis Working Party for 1979. The report set out the results of surveillance for 1978 and 1979. It narrated:

This year has seen the completion of the first year of the surveillance programme financed by a grant from the Department of Health and Social Security. This is part of a three year programme. The second part of the project consists of an investigation for evidence of chronic liver disease in haemophiliacs on long term factor VIII therapy.<sup>215</sup>

**21.228** The report stated:

The prevalence of hepatitis in 1978 and 1979 has had about the same level as that observed in 1976-77. There has been an increase in the proportion of cases of N/A, N/B hepatitis reported in patients with mild coagulation defects receiving concentrate for the first time to cover operations .... The observed increase in mild haemophiliacs contracting hepatitis is probably due to the fact that most severe haemophiliacs have already been exposed to viruses present in all brands of concentrate and are therefore immune to re-infection. Patients with mild haemophilia have not so been exposed; therefore there is no evidence to suggest that the contamination rate of different brands or batches of concentrate with N/A, N/B viruses has diminished.<sup>216</sup>

**21.229** The main conclusions of the working party were that:

1. Transaminitis is unrelated to current factor VIII therapy and the level of anti HBs antibody.
2. Transaminitis is unrelated to a previous history of overt hepatitis.

This is supported by the observation that in 6 out of 7 cases of jaundiced patients observed at Oxford in the past year, the liver function tests quickly returned to normal after the acute attack ....

These results suggest that if transaminitis is related to viral hepatitis, the patients who become carriers and develop chronic liver disease will only contract mild or symptomless acute hepatitis, and the most overtly jaundiced patients will fully recover. This is supported by our observations of hepatitis B infections in haemophiliacs ....<sup>217</sup>

**21.230** 'Transaminitis' was emerging as a descriptive condition identified by biometric abnormalities. At this time it seems that there was some ambiguity in the use of the expression. It is not clear whether those who used the term associated 'transaminitis' with ongoing liver inflammation (hepatitis) or with more established liver damage. However, these conclusions show that among haemophilia doctors, as among hepatologists, there was increasing realisation that chronic liver disease might be associated with persistent

<sup>217</sup> Ibid [LOT.003.5679] at 5684

mild liver test abnormalities – ‘transaminitis’ – and possibly a carrier state. Furthermore, it was now realised that liver damage and disease might arise in the absence of symptoms.

**21.231** The minute of the UKHCDO meeting on 30 September 1980 stated:

Large pool concentrates appeared to give a higher risk of hepatitis than small pooled concentrates and Dr Craske felt that increased usage of small pooled concentrates would help to reduce the incidence of hepatitis in the haemophilic population. First-time exposure to large pooled factor VIII concentrate resulted in many cases of hepatitis, especially in von Willebrand’s disease patients. Professor Bloom wondered whether cryoprecipitate would be a better product to use for mild haemophiliacs and von Willebrand’s disease but pointed out that there was a problem over the amount of factor VIII in these materials. Dr Craske agreed and he said that the NHS product was certainly better than the Commercial products because of the screening of the blood donors and the regular donor panels which were used in the U.K. The screening procedures for donors of plasma used to make Commercial factor VIII is radioimmunoassay but because of the unstable population and the poor social background, it is likely that there will be a higher incidence of carriers of the hepatitis virus than in the U.K. volunteer blood donors.<sup>218</sup>

**21.232** There was no reported discussion, in the Hepatitis Working Party Report, or at the meeting on 30 September 1980, of the need or desirability for a fundamental reassessment of, or change in, the Haemophilia Directors’ approach to product selection. In Scotland, over the next six months there were discussions relating to the use of cryoprecipitate, but records do not disclose serious concern among haemophilia clinicians of adverse consequences from the use of the PFC concentrates.

**21.233** At a meeting of Directors of the SNBTS and Haemophilia Directors on 30 January 1981 held in Edinburgh, Professor Cash spoke about cryoprecipitate and emphasised that it should be seriously considered for home therapy.<sup>219</sup> Home therapy was increasing and would place such a strain on resources that all options had to be included. The Haemophilia Directors were generally not in favour of using cryoprecipitate for home therapy as they considered the risks of side-effects were too great. They were prepared to use cryoprecipitate in hospitals.

**21.234** When Professor Cash appeared at the Inquiry he explained his reason for recommending cryoprecipitate to meet the therapeutic needs of haemophilia patients. He said:

As a person responsible for self-sufficiency, so I thought, I was drawing attention to my colleagues, not just saying, ‘Keep going with cryoprecipitate chaps’, but cryoprecipitate was much higher yielding than John Watt’s PFC’s concentrates, and that applies across the world. So if you switched fast from cryoprecipitate to concentrate, from the point of view of self-sufficiency, you were going to need a lot more plasma to stay still. And I actually suggested we gave just a thought before we rushed down that track, and that’s all that that was really about.<sup>220</sup>

<sup>218</sup> Minutes of UKHCDO meeting, 30 September 1980 [SNB.001.7296] at 7305

<sup>219</sup> Minutes of meeting of SNBTS Directors and Haemophilia Directors, 30 January 1981 [SNB.001.5055] at 5056

<sup>220</sup> Professor Cash – Day 25, page 113

His advocacy of cryoprecipitate was not based on apprehension of risk related to Factor VIII concentrate.

**21.235** At the joint meeting on 30 January 1981, Dr Albert Bell of SHHD introduced paper 81/2, regarding the Council of Europe recommendation concerning blood products for the treatment of haemophilia.<sup>221</sup> The Directors agreed that policy and practice in Scotland were consistent with the recommendations urging Member States to become self-sufficient and to follow guidelines for the preparation and use of blood products. Professor Forbes told the Inquiry that he was not aware of this recommendation and admitted he knew nothing about the Council of Europe and their role in relation to blood products at that time.<sup>222</sup>

**21.236** Concern was expressed again at a meeting of the Scottish Haemophilia and Blood Transfusion Working Group held on 4 March 1981 about the level of commercial material being purchased.<sup>223</sup> It was agreed that the aim must be for the NHS in Scotland to be self-sufficient. This could be achieved with good planning and steps had been taken to improve the input of plasma. Professor Cash again spoke in favour of cryoprecipitate highlighting two factors:

- The increased yield.
- The increased pool size (although acknowledging that there was a school of thought in the UK that the larger pool size may increase the risk of hepatitis).

**21.237** Professor Cash urged members to bear in mind the allergic reactions and side-effects which could arise. He commented that the majority of home therapy patients had no problems when using cryoprecipitate and in Belgium it was used extensively. Professor Cash did not develop the argument, and the context indicates that his primary concern at this stage was still related to supply.

**21.238** The meeting then agreed that Professor Cash and Dr Foster would monitor ongoing studies in relation to the improvement of the yield of intermediate Factor VIII and the development of a product of higher potency. Dr Foster also drew attention to the importance of reporting adverse reactions to the PFC products. This was necessary to meet the requirements of the product licence but also gave the PFC the opportunity to withdraw other material of the batch giving rise to suspicion pending investigation. The discussion reported gave no indication that the Haemophilia Directors present considered that there were serious risks of adverse reactions: the discussions related to procedural difficulties in devising a reporting system.

**21.239** On 4 July 1981, an editorial in the *BMJ* set out the risk to haemophilia patients in rather more stark terms. It narrated:

Despite advances in screening donors and in blood fractionation, post-transfusion hepatitis remains the major complication of the modern treatment of haemophilia. The diagnosis is usually inferred from abnormalities in the results of hepatic biochemical tests rather than from clinical evidence. Surveys in haemophiliacs have shown changes in the liver architecture consistent with previous viral assault, including those of chronic persistent and chronic active

<sup>221</sup> Minutes of meeting of SNBTS Directors and Haemophilia Directors, 30 January 1981 [SNB.001.5055] at 5057

<sup>222</sup> Professor Forbes – Day 17, pages 83–84

<sup>223</sup> Note of meeting of Haemophilia and Blood Transfusion Working Group, 4 March 1981 [SNB.001.5064]

hepatitis and of cirrhosis. Indeed, in some cases early death from liver disease might prove to be the price paid by haemophiliacs for the improved quality of life afforded by the easy availability of clotting-factor concentrates.

So while no one doubts that the only way to treat haemorrhage in severe haemophilia is by rapid replacement of the relevant clotting factor, considerable thought is being given to reducing the risks. Attention has focused on three practices: the risks of collecting plasma from paid as opposed to volunteer donors; the optimum size of the plasma pool; and attempts at removing the several viruses of hepatitis from blood products.

The risks of viral contamination are certainly increased if plasma is obtained by plasmapheresis of paid donors. True, the sensitivity of testing for hepatitis B has been improved so that its incidence in patients given multiple transfusions is about the same from either paid or volunteer sources, but hepatitis B is a relatively minor problem.<sup>224</sup>

**21.240** The article went on to identify NANB viruses (at least two) as the main cause of chronic liver disease in patients with haemophilia. In relation to the volunteer/paid donor issue, the editorial provided relevant evidence of a material reduction in risk when a hospital changed from commercial to volunteer blood. In relation to the second factor, there was again relevant evidence. The final paragraph stated:

Thirdly, is it likely that the recipients of multiple transfusions can be immunised, or that the threat of hepatitis can be removed from donated blood entirely? Immunisation against hepatitis B is certainly a possibility, but, in the absence of specific markers for non-A, non-B hepatitis, overall protection against hepatitis appears remote. A more likely possibility is that hepatitis-free blood products will become available ...<sup>225</sup>

**21.241** The editorial referred to three recent reports dealing with heat-inactivation,  $\beta$ -propiolactone, and wet-heat treatment processes as more likely to achieve the removal of viral contamination.

**21.242** The third and final Annual Report of the three-year retrospective study financed by the DHSS (project no J/S240/78/7) was produced by the Oxford Haemophilia Centre on behalf of the UK Haemophilia Centre Directors for the year 1980–81.<sup>226</sup> The report, written by Dr Craske and dated 24 September 1981, covered a series of cases of Factor VIII and IX related hepatitis in the UK. Haemophilia Centre Directors had reported 283 episodes of hepatitis relating to 253 patients. Of those, 197 episodes were non-B Hepatitis and were therefore thought probably to be non-A, non-B incidents. There were 86 incidents of Hepatitis B. The incidence of Hepatitis B continued to decline as the sensitivity of screening tests for infectious HBV improved. As published, the report was little different in its terms from the report presented to the UKHCDO Hepatitis Working Party at Glasgow on 30 September 1980. The final report stated:

The question of the significance of chronic hepatitis observed by several groups of workers in liver biopsies of patients with chronically elevated transaminases is still unanswered. Current investigations are attempting to relate the results

<sup>224</sup> 'Post-transfusion hepatitis', *British Medical Journal*, 1981; 283/6283: 1–2 [LIT.001.0227]

<sup>225</sup> Ibid [LIT.001.0227]

<sup>226</sup> Haemophilia Centre Directors' Hepatitis Working Party report for 1980–81 [DHF.001.1711]

in different groups of patients to their transfusion history, and there is strong evidence that different types of non-A, non-B hepatitis are related to different products .... Most patients in this group are still entirely symptomless. The natural history of the disease in non-haemophiliacs is still not known ....<sup>227</sup>

**21.243** The incidence of overt NANB Hepatitis infection associated with US commercial concentrates was 4–20 times higher than that associated with the NHS product. There had been no further deaths directly or indirectly attributable to liver disease in the past year. This report was very significant because it implied that, by 1981, the vast majority of severe and moderately severe haemophilia patients already had NANB Hepatitis. It stated:

The chief finding is that 70-80% of cases of non-A, non-B hepatitis were associated with the first dose of concentrate that the patient received.<sup>228</sup>

**21.244** This was subsequently shown to be the case. The corollary was thought at the time to be that:

Most of the patients treated with any batch of concentrate will be immune to non-A, non-B hepatitis, since batches of concentrate of any brand are contaminated with one (or more) serotypes of these agents.<sup>229</sup>

**21.245** Dr Craske presented this report at the 12th meeting of the Haemophilia Centre Directors on 9 October 1981.<sup>230</sup> He recommended continued surveillance; a study of sub-clinical hepatitis; collection of data on batch numbers; need for post-mortem liver samples; and hepatitis-free concentrates.

**21.246** This report summarised the findings of the survey. Dr Craske had several recommendations to make including:

- Surveillance should continue.
- A multi-centre prospective study of hepatitis in first time/seldom treated patients was planned. This group seemed to have a higher risk of contracting NANB Hepatitis whatever type of material was used for their treatment.
- The working party to continue to collect data on the batch numbers of materials received by patients who developed hepatitis.
- Some commercial firms had claimed that a hepatitis-free Factor IX concentrate was available. Dr Craske thought this may well be true but there were problems in proving the safety of each batch of concentrate as only a limited number of laboratory animals were available for testing the materials.

**21.247** There was some critical comment on Dr Craske's methodology. He had still not overcome the scepticism of some members of the group. Nevertheless, this report shows that enormous progress in understanding the size and nature of the problems of hepatitis in haemophilia patients had occurred in the three years since the initial survey report of 1978.

<sup>230</sup> Minutes of meeting of UK Haemophilia Centre Directors, 9 October 1981 [SNB.001.7354] at 7372

**21.248** Paragraph 6.79 of the Preliminary Report commented:

Throughout this period there was a debate taking place in the medical community. On one side the view was held (mainly by virologists and public health doctors) that haemophilia patients should not be given concentrates because it was not known what viruses were being transmitted to them. The contrary view (mainly held by the Haemophilia Society and haemophilia doctors) was that concentrates should continue to be given because they transformed the lives of haemophilia patients and hepatitis appeared to be a relatively benign condition.

**21.249** When Professor Forbes appeared at the Inquiry he was asked whether he thought this summarised the points of view at the time. He replied:

All these papers were highlighting something that we did know and understand, that hepatitis was a problem. How much of a problem we didn't really grasp initially, and it's only as these papers came out – the first was Eric Preston, and I think it was liver biopsy he used, and we were appalled that so many of the patients clearly had liver disease and that was then confirmed by the Mannucci paper and so on. So we were gradually becoming aware that the use of all these blood products was not as benign as we thought it was.

....

We started to feel anxious about the use of the products that we gave, which were so wonderfully life-changing for the patients, and that's why, of course, the Haemophilia Society didn't want to change anything. They wanted to go on and give as much product as possible. Because it was thought that the hepatitis that clearly was there was a pretty benign disease, not so eventually, but there we are. That was the state of play.<sup>231</sup>

**21.250** By 1981, a more cautious use of Factor VIII concentrates made from large plasma pools was beginning to be supported, by haemophilia centre clinicians among others. Professor Mannucci's recommendation of DDAVP has already been noted. A similar point was made in 1981 in a study from the University of Gothenburg, Sweden, reported by Norkrans and colleagues.<sup>232</sup>

**21.251** The search for alternative therapeutic materials reflected a degree of growing concern about the use of large-pool factor concentrates. However, there was as yet no change in practice: as the growing use reflected in Figures 1 and 4 indicates, despite the concern about transmission of hepatitis, haemophilia practice throughout the UK continued to depend largely on the use of concentrates.

### Choice of products

**21.252** As noted at the beginning of this chapter, there were good reasons for the selection of specific products to meet specific needs in some cases. However, the Inquiry was aware of comment that individual haemophilia doctors may have been influenced in their selection of commercial products by factors other than the clinical needs of the

<sup>231</sup> Professor Forbes – Day 17, pages 63–64

<sup>232</sup> Norkrans et al, 'Acute hepatitis non-A, non-B following administration of Factor VIII concentrates', *Vox Sanguine*, 1981; 41:129-33 [LIT.001.0743]

patient. The origin of this view, for the most part, appears to have been Douglas Starr's book *Blood*. It is possible to comment only in relation to practice in Scotland.

**21.253** In *Blood*, the relationship between the commercial companies and treatment providers was described as 'cosy'. Douglas Starr was talking specifically about Germany where almost all of the therapeutic material had been bought from the USA. It cost only a quarter to a third as much as the German-made product. But the suggestion was that this type of relationship appeared to be commonplace throughout the advanced world. Douglas Starr wrote: 'Most of the World Haemophilia Federation's budget was paid for by the fractionation companies, who picked up the tab for its lavish annual meetings ...'.<sup>233</sup>

**21.254** Douglas Starr also commented that the National Hemophilia Foundation in the USA received anywhere from 15–25% of its operating budget from the industry as well as special grants for educational projects. He said:

The doctors and the hemophilia organizations argued that the relationship was appropriate and collegial, not coercive. They saw it as a mutual exchange of medicine, money, and information to help their patients get as much clotting factor as they needed at the best prices. Yet patients would later claim that the financial links between the drug companies and the doctors influenced the treatment providers to be complacent about safety.<sup>234</sup>

**21.255** When giving evidence to the Inquiry, Professor Forbes was asked whether he was aware of a cosy relationship of the kind described. He replied: 'I have never been at any meetings that were lavish. So I must have missed out on that'.<sup>235</sup> In the UK, a Symposium on Haemophilia held in Glasgow on 19 September 1975 was sponsored by Travenol.<sup>236</sup> When asked about sponsorship of this symposium, Professor Forbes replied that he did not remember the detail but must have been there. He thought that the sponsors would support the travel of some of the speakers and they may even have paid for accommodation, if required.<sup>237</sup>

**21.256** The evidence set out at paragraphs 21.301 to 21.306 below, relating to the succession from Dr Willoughby to Dr Hann at Yorkhill shows how, in the exercise of their clinical judgement, haemophilia doctors differed in the selection of therapeutic products. Individual clinicians had their preferences, and, objectively, some preferences may have been based on grounds of varying substance.

**21.257** There was, however, no evidence before the Inquiry that would support a finding that Scottish practitioners were influenced in their choice of therapeutic products by benefits provided by pharmaceutical companies in the way hinted at by Starr.

**21.258** The DoH scheme for England and Wales provided for the distribution of NHS products to regions pro rata to the contributions of plasma made for fractionation. At all material times, NHS output was insufficient to meet total demand. The unmet balance of demand was provided by commercial purchases funded by regional health authorities. That allowed for variations within regions. The arrangements for procuring therapeutic

<sup>237</sup> Professor Forbes – Day 17, pages 48–49

products in England, and particularly in London and the south east of England, including Canterbury and Thanet, were described by Dr Winter. In some respects, they were very different from arrangements in Scotland. Dr Winter said that individual Haemophilia Directors exercised autonomy in the selection of therapeutic products.<sup>238</sup> It was for the individual to form a view of NHS and commercial concentrates. They would ascertain how much NHS product was likely to be available for the year, and then enter into negotiations, along with procurement colleagues, with a commercial company for purchase of the concentrate of their choosing.<sup>239</sup> In London and the south east, the position was different. Two major centres, St Thomas' Hospital and Kent and Canterbury, had budgets for commercial purchases while others, perhaps 15 small centres, had little or none. It was agreed to allocate NHS material preferentially to them. As a result, Dr Winter used a relatively small proportion of NHS concentrates in his practice.<sup>240</sup>

**21.259** Dr Winter's evidence indicates that national government policy on distribution of available NHS concentrates might have, at best, an indirect bearing on clinical practice and the risks to which patients were exposed. It also indicates clearly that haemophilia clinicians were closely involved in decisions about the procurement and use of commercial products.

#### *Edinburgh and south east Scotland*

**21.260** UKHCDO data on therapeutic products used in managing patients with Haemophilia A in Edinburgh and south east Scotland are summarised in Table 21.3 in the Appendix to this chapter, and shown graphically in Figure 21.8. In the Figure, cryoprecipitate and fresh frozen plasma quantities have been aggregated. DDAVP values have been omitted since they are insignificant in quantity. The picture that emerges is for the period from 1969–91. It provides a quantified historical account as background to the written and oral evidence available to the Inquiry.

<sup>238</sup> Dr Winter – Day 16, page 78

<sup>239</sup> Ibid page 77

<sup>240</sup> Ibid pages 78–79

**Figure 21.8: Edinburgh Haemophilia A Therapy in Million International Units (Miu) – 1969–91**

**21.261** When Dr Davies was in charge, up until 1980, locally produced cryoprecipitate and PFC's concentrates were preferred in the region. As Figure 21.8 demonstrates, Dr Davies clearly made extensive use of cryoprecipitate. He also made not insignificant use of PFC concentrates but took the precautionary view that cryoprecipitate involved fewer donors and was less likely to transmit infections known and unknown. Edinburgh used almost no commercial product under Dr Davies' stewardship.<sup>241</sup> Until 1975, the PFC concentrates were small pool AHF Cohn Fraction I concentrates and for the last three or four years of Dr Davies' period, PFC concentrates made from relatively large pools. Dr Davies used 500 units of commercial Factor VIII in 1974, a unique departure from his general practice, and otherwise prescribed SNBTS products. Professor Ludlam told the Inquiry that Dr Davies had a cautious attitude towards the use of imported commercial Factor VIII concentrate policy. He did not use commercial concentrates because of the uncertainty about hepatitis viruses, in part because he considered the domestic product to be generally safer than concentrates derived from plasma collected in the USA and elsewhere, and in part because he did not want to expose his patients to viruses that might be novel to the local community.<sup>242</sup>

**21.262** Professor Ludlam said that he had tried to follow Dr Davies' policies when he came to Edinburgh in 1980. However, he was interested in introducing home treatment, and was not enthusiastic about home treatment with cryoprecipitate, as discussed earlier at paragraphs 21.101 to 21.106.

<sup>241</sup> Professor Ludlam – Day 18, pages 88–89. See also Professor Ludlam's statement on the use of blood product concentrates [PEN.015.0445] at 0458

<sup>242</sup> Professor Ludlam – Day 19, page 125. Professor Ludlam's report Edinburgh Haemophilia Treatment Policy [PEN.015.0375] at 0379

**21.263** However, in the early 1980s demand for home treatment put pressure on the available supplies of PFC Factor VIII concentrate, and Professor Ludlam said that during 1981 and 1982 a small amount of commercial concentrate was purchased to treat a small number of patients with specific haemostatic therapeutic difficulties, or, in one case, to provide home treatment to one of two patients who lived at some distance. The other was on home treatment for other reasons.<sup>243</sup> In 1980, Professor Ludlam had six patients on home therapy out of 187 registered with his centre. Five per cent of the product used was commercial.<sup>244</sup> By 1983, when Professor Ludlam had transferred most of his patients to concentrates, he had managed to maintain most of them on Scottish product.

**21.264** Following Professor Ludlam's appointment, there was a significant increase in the use of therapeutic materials generally, met in part by commercial purchases. As compared with Dr Davies' practice, use of cryoprecipitate, initially at a peak in 1980, began to fall, reaching a low point in 1987 before rising again in 1989 when there was a major readjustment of the balance between SNBTS and commercial products, and, within the SNBTS range, between cryoprecipitate and PFC Factor VIII. There was an immediate and significant increase in demand for concentrates in 1980 and following years. The shortages of PFC Factor VIII at the beginning of the 1980s described by Dr Foster were reflected in an increase in commercial purchases.

**21.265** So far as commercial products are concerned, use began in 1980 and grew in 1981 as Professor Ludlam's approach to therapy took effect, and then fell until 1988 when there began a significant and sustained increase. There was also a change in the commercial products used after the initial unsettled period, when Factorate was used to make good the limitations in NHS production. From 1982 until 1987 the main products from commercial sources contributing to the total were FEIBA and porcine Factor VIII. From 1988 a wider range of Factor VIII products were purchased including Monoclate, Profilate, Octapharma Factor VIII and Hemofil-M in addition to FEIBA and porcine Factor VIII.

**21.266** Professor Ludlam said that for patients with severe Haemophilia A there were two treatment options: cryoprecipitate and NHS Factor VIII concentrate. Patients were very keen to get onto Factor VIII concentrate and home treatment. Initially, concentrate was in 'desperately short supply'.<sup>245</sup> At that stage he had to delay introducing patients to home treatment because of the lack of NHS concentrates and patients were unhappy about it.<sup>246</sup> A large-scale effort had gone into scaling back cryoprecipitate production and scaling up the manufacture of concentrate to enable patients to be treated at home.<sup>247</sup> Over the period, the SNBTS succeeded in increasing production and meeting demand for Factor VIII concentrate, with commercial purchases reducing as a result until 1988.

**21.267** The graph in Figure 21.8 suggests a more complex picture. The initial surge in use in 1980 to meet Professor Ludlam's new approach to therapy clearly stretched the PFC's capacity. The reduction in use of cryoprecipitate in 1981 was balanced by increasing supplies of the PFC Factor VIII in and after 1982. Dr Foster's evidence indicated that the switch to commercial products in 1980 and 1981 was driven by the need to make good, shortages in the domestic product in order to meet Professor Ludlam's requirements. The first year or two of the 1980s saw a radical change in clinical policy.

<sup>243</sup> Professor Ludlam – Day 18, pages 70–73

<sup>244</sup> Ibid pages 88–89. See also Professor Ludlam's statement on the use of blood product concentrates [PEN.015.0445] at 0458

<sup>245</sup> Professor Ludlam – Day 35, page 28

<sup>246</sup> Ibid page 26

<sup>247</sup> Ibid pages 26–27

**21.268** Overall, the data tabulated for Edinburgh reflect broadly the balance Professor Ludlam was aiming for, though the proportions differ. About 9% of Edinburgh's Factor VIII supplies in 1980 were commercial. That rose to over 34% in the following year before falling back to about 8% by 1983. Commercial purchases were significant as Professor Ludlam introduced home therapy, but fell rapidly at the same time as the risk of AIDS was becoming more firmly associated with a transmissible agent or, on his analysis, progressive immune compromise caused by reaction to antigen overload.

**21.269** Over the same period, from the 1970s to the mid-1980s, therapy for Haemophilia B had progressed from treatment with fresh frozen plasma to Factor IX concentrate, which itself developed over time from a combination product, including several factors, to a concentrate composed of Factor IX alone.<sup>248</sup> Professor Ludlam was able to use Scottish products for most patients.

**21.270** So long as the PFC supplies continued to meet the demand for concentrates among Professor Ludlam's patients, the position in Edinburgh and south east Scotland, as presented by Professor Ludlam, was close to the ideal. Products produced locally from blood donated in Scotland were used more or less exclusively in haemophilia therapy. The Council of Europe Committee of Ministers 'Recommendation No R(80) of 30 April 1980: Concerning Blood Products for the Treatment of Haemophiliacs', stated that Member States should pursue the goal of self-sufficiency in antihemophilia products and blood plasma for their preparation. The Recommendation acknowledged the fact that both the geographical origin and type of donor population had a significant effect on the risks of infectious diseases.<sup>249</sup> Professor Ludlam's arrangements would have satisfied that recommendation if his area of operation had been a state.

**21.271** Dr McClelland joined the service in Dr Davies' period. He said of his early experience:

As a first year junior house officer in 1969, I was privileged to work for the late Dr Howard Davies, an Edinburgh Royal Infirmary consultant physician who cared for patients with haemophilia. Dr Davies was a strong proponent of cryoprecipitate rather than factor VIII concentrate. I remember clearly that his rationale for this struck me as being eminently sensible. It was that by avoiding the use of products made from the blood of thousands of donors, especially those from other corners of the world, one was almost bound to reduce the risks of passing on infections, known or unknown, to the patients.<sup>250</sup>

**21.272** The observation does not quite fit the pattern of use demonstrated in the graph at Figure 21.8, though the contrast was with concentrates prepared from 'thousands' of donations, the position in commercial production rather than at the PFC. Subject to that, Dr McClelland's comments reflect the picture in Figure 21.8.

**21.273** Dr McClelland commented specifically on Dr Davies' preference for local products, rather than imported products, as a way of minimising infection. He told the Inquiry:

[I] think his view was as a sort of matter of fairly elementary biology: the more, as it were, different donors' blood samples contributed to the dose

<sup>248</sup> Professor Ludlam – Day 18, pages 46–48

<sup>249</sup> Council of Europe Committee of Ministers, 'Recommendation No R(80) 5 of the Committee of Ministers to Member States Concerning Blood Products for the Treatment of Haemophiliacs' (Adopted by the Committee of Ministers on 30 April 1980 at the 318th meeting of the Ministers' Deputies) [DHF.001.0507]

<sup>250</sup> Dr McClelland's statement on the use of blood product concentrates [PEN.015.0307]

that one received as a patient, arithmetically the risk of getting something nasty was increased, and the further afield the blood came from, there was a certainly incalculable but reasonable grounds to expect that something new and different and unfamiliar to the indigenous population might be in that blood.<sup>251</sup>

**21.274** As described by Dr McClelland, the reasoning was not complicated, but it explained clearly the pattern of use of materials in Edinburgh during Dr Davies' period. Professor Ludlam was prepared to use commercial products, in particular Armour's Factorate Factor VIII, which was not heat-treated to any extent until 1984.<sup>252</sup> There is no basis in evidence, however, to doubt that the early use of Factorate was a response to shortage of the SNBTS product rather than a matter of choice.

**21.275** Apart from putting pressure on the SNBTS by changing clinical practice, the Edinburgh Centre took steps to protect individual patients when they were away from home. A national system in use since the 1970s provided every patient diagnosed with haemophilia with a card stating what their condition was, the level of severity, which haemophilia centre they were registered with and where to phone in an emergency. Professor Ludlam said:

Patients were individually told to request either cryoprecipitate or an NHS concentrate and to avoid a commercial concentrate if possible. To emphasise the importance of this each patient was supplied with a small statement to this effect, which was placed in their haemophilia card, which they could then show to get treatment at another Centre.<sup>253</sup>

**21.276** This step was initiated because patients might travel to England and if they required treatment there was a possibility they might get an injection of commercial concentrate.<sup>254</sup> It gave added emphasis to the continuing preference for NHS products, where possible, after Professor Ludlam took over from Dr Davies in 1980. Professor Ludlam had a research interest in monitoring a group of his patients treated solely with NHS product. The card system supported monitoring.<sup>255</sup> But there is no reason to treat this as other than an incidental aspect of treatment policy.

**21.277** Dr Boulton took up his post in Edinburgh in 1980. In his oral evidence, he talked about the different forms of therapy available for the patients at that time, comparing perceptions of the SNBTS product then and later:

[A]s time went by, I did become aware of views that there were problems with fractionated product, even from NHS volunteer donors. But I think it was not unreasonable for the newer generation to advocate an increase in usage of Factor VIII.

The problem was that if one were to restrict the use to what, at that time, was felt on good grounds but not on established grounds, to be a safer product, ie a cryoprecipitate that was more difficult to use, less potent, the patients would not have so much protection from joint damage, whereas one would be able,

<sup>251</sup> Dr McClelland – Day 21, pages 153–154

<sup>252</sup> The commercial products used in Edinburgh from 1988 were heat-treated.

<sup>253</sup> Professor Ludlam's report, *Edinburgh Haemophilia Treatment Policy* [PEN.015.0375] at 0380

<sup>254</sup> Professor Ludlam – Day 18, pages 68–69

<sup>255</sup> *Ibid* pages 72–73

with higher doses of smaller volume infusion lyophilised from the freeze-dried fractionated product, be able to embark on a programme of prophylactics for preventing the damage to joints, particularly in boys as they were approaching their teens.<sup>256</sup>

**21.278** The dilemma for clinicians could only be resolved by the exercise of judgement. Dr Boulton pointed out that Professor Ludlam was anxious to increase the use of Factor VIII for the haemophilic patients, particularly the young ones.<sup>257</sup> In Dr Boulton's view, Professor Ludlam was right to move away from cryoprecipitate treatment and towards the use of more Factor VIII for treatment of haemophilia patients. At that time they had no inkling of HIV/AIDS but did of course know about hepatitis.

**21.279** Dr Boulton and his colleagues thought that the process of blood donor selection and testing and ever better hepatitis screenings would result in a quality of plasma sent for fractionation that would be as risk-free as possible.<sup>258</sup> He considered the PFC product to be as good a quality product as could be obtained anywhere in the world and on a par with commercial firms. But the commercial firms developed a very good marketing strategy. The packaging, the literature with attractive pictures etc were of a standard way beyond the budget of the PFC.

**21.280** The change of practice in Edinburgh, including the use of commercial products during the early part of Professor Ludlam's tenure, reflected the state of knowledge at the time. No single factor explains the whole picture, however. There were specific cases where commercial product was preferable for the particular patient. Some patients did not tolerate the PFC intermediate concentrate, for example, and for them a commercial alternative was prescribed. That apart, Professor Ludlam promoted home treatment to a greater extent than Dr Davies and that explains his resort to commercial concentrates in 1980 and the next few years.<sup>259</sup> The PFC had to gear up production to meet increasing demand generated by changes in treatment policy, increasingly towards home treatment.

**21.281** But the picture is complicated by other factors. By the end of the 1970s there were growing and widespread concerns about the use of concentrates related to risk of transmission of NANB Hepatitis. However, there was no evidence of a shift to cryoprecipitate at that stage. Later, in 1982–83, some clinicians in the USA, in particular Dr Oscar Ratnoff, attempted to move patients back to cryoprecipitate, but this was resisted by patients who wished to continue taking concentrates.<sup>260</sup> Figure 21.8 shows use of cryoprecipitate increasing in 1979, peaking in 1980 and then beginning to fall, but on Professor Ludlam's evidence this could not be said to relate to a policy decision relating to transmission risk. He told the Inquiry that he did consider switching his patients from factor concentrates to cryoprecipitate in 1982–83 (as happened in some parts of England and Wales). He discussed the possibility with his colleagues in the SNBTS and they did not look at all favourably upon being able to achieve it within the timescale. He thought the possibility was discussed informally with Dr McClelland and Dr Boulton. He said that all three had offices close together and used to talk about these sorts of things. It may also have been discussed in a more formal context but he could not recall this happening.<sup>261</sup>

<sup>256</sup> Dr Boulton – Day 24, page 16

<sup>257</sup> Dr Boulton – Day 24, page 18

<sup>258</sup> Ibid pages 102–103

<sup>259</sup> See paragraphs 21.103–21.110

<sup>261</sup> Professor Ludlam – Day 35, pages 29–30

**21.282** The wider picture at the time was of increasing emphasis on scaling up concentrate production at the PFC, not least to meet Professor Ludlam's requirements. The SNBTS was putting all its effort into improving the PFC's plant for concentrate production.<sup>262</sup> The logistics of making the switch to cryoprecipitate would have been huge, and, in treatment terms, it seemed a retrograde step.<sup>263</sup> A large effort had gone into scaling up the manufacture of factor concentrates, which enabled patients to be treated at home.<sup>264</sup> Professor Ludlam would have had enough cryoprecipitate to switch one or two patients back to it but if there was to be a wholesale move back to cryoprecipitate his understanding was that it would have taken some time for the SNBTS to change course in manufacture. It would have required huge changes to the manufacturing practices.<sup>265</sup> It would have taken time to acquire the necessary production equipment, train staff and obtain the required consumables.<sup>266</sup>

**21.283** As Figure 21.8 shows, from 1982–87, use of cryoprecipitate decreased, the SNBTS Factor VIII concentrate was the principal product used, and use of commercial products fell to a very small percentage of total Factor VIII usage. Professor Ludlam was asked about alternatives to the standard treatment options for patients with severe Haemophilia A. The alternatives discussed were:

- i. No treatment (although this was not an option if the patient was bleeding).
- ii. Reducing the amount of factor concentrate (including switching from prophylactic treatment to on-demand treatment).
- iii. Treatment with cryoprecipitate.
- iv. From 1984 onwards, the use of commercial heat-treated Factor VIII concentrate.

**21.284** In Professor Ludlam's view, the first course proposed was not appropriate. He explained that the risks that arose from not treating patients greatly outweighed the risk of transmission of infection, a view generally shared by other haemophilia clinicians. In addition to the practical difficulties already mentioned, switching to cryoprecipitate would not eliminate the risk of transmission of infection entirely.<sup>267</sup>

**21.285** The second option raised a more technical issue. In the period 1982–84, Professor Ludlam had studied abnormalities in the immune systems of patients.<sup>268</sup> When he received the results of immune function tests showing reductions in CD4 counts, he considered whether the results were related to the amount of concentrate the patient had received over the past two or three years. He was very quickly able to go back over several years' worth of transfusion records and there seemed to be no correlation between the immune abnormalities, and the amount of factor concentrate the patient had received. There was nothing to suggest that if patients used less concentrate this would result in fewer immune abnormalities.<sup>269</sup>

<sup>268</sup> See Chapter 11, *HIV/AIDS Aetiology*, paragraphs 11.65–11.72

<sup>269</sup> Professor Ludlam – Day 39, pages 16–17

**21.286** Professor Ludlam accepted that it was possible that certain patients might not have seroconverted if the amount of factor concentrate they received had been reduced at an earlier stage. However, the issue was not straightforward. At this period (in the mid-1980s), all treatment at the Edinburgh Haemophilia Centre was on demand, that is in response to the patient suffering a bleed, and usually at home. If patients used less Factor VIII or chose not to treat bleeds as intensively as they might have normally, they might actually require a lot more treatment to settle the bleed. Professor Ludlam explained that bleeds into joints (particularly elbows and knees) can be extremely painful and can last for several days. An untreated knee bleed, for example, will last about a week to 10 days. If not treated from the outset the pain becomes so great that patients may require large amounts of morphine or pethidine. At that point, the patient might opt for treatment and would then require a lot more treatment to settle the bleed than if he had commenced treatment from the beginning. If a bleed was treated very early on then usually a single injection was enough, whereas if the bleed was left to develop over several days, the patient needed an awful lot of treatment and therefore a lot of Factor VIII.<sup>270</sup>

**21.287** Professor Ludlam said that occasionally patients presented with recurrent bleeds into a joint (typically where they had received a short course of treatment in response to a bleed and then had re-bleed). One possible course of treatment under those circumstances was to treat the patient for two or three months, often every day, to try and keep the factor level up to stop the recurring bleeding.<sup>271</sup> Circumstances varied. Professor Ludlam's evidence was that he considered carefully all of the treatment options in selecting the appropriate course before deciding what was in his patients' best interests. The second option, of reducing the amount of concentrate infused, did not provide a generally acceptable approach. The third option, increased use of cryoprecipitate, was subject to the limitations on supply already discussed. More generally, on Professor Ludlam's approach it was one of the range of treatment options to be considered on an individual basis.

**21.288** So far as use of commercial products is concerned, Figure 21.8 reflects a shift in policy in and after 1988, implicit in the pattern of usage. Views were developing at that time about the ease of use of commercial Factor VIII products because of their high purity; relative to the SNBTS product. Professor Ludlam had also observed immune abnormalities in some of his patients that were not associated with viral infection, but were hypothesised to be associated with protein impurities in the PFC products. Until late 1984 there was confidence in the relative safety of the SNBTS product. Steps taken at the end of that year to inactivate HIV in the PFC's intermediate Factor VIII product proved to be successful. The question whether any products were 'safe' from transmission of NANB Hepatitis/HCV is discussed in other parts of this Report.

**21.289** Having regard to the evidence as a whole, there is no basis for a view that Professor Ludlam's general practice was other than as described by him: decisions on therapy were made on an individual basis, with a clear bias towards the use of SNBTS products in most cases, consistently with the policy of his predecessor. Decisions were made on professional grounds. There was no suggestion that he was influenced by any considerations other than his patients' welfare, and there is no basis for inferring that he was. Professor Ludlam's research interests are considered later, in the context of information and advice tendered to patients. However, in the Inquiry's view, these interests did not influence his choice of therapeutic product for the treatment of his patients.

### *Glasgow and west of Scotland*

**21.290** When looking at the picture that emerges in Glasgow and the west of Scotland it is important to take account of the division of clinical responsibility between two treatment centres. Until their teens, children received specialist management of their blood coagulation disorders at West of Scotland Children’s Comprehensive Care Haemophilia Centre at Yorkhill Hospital. Thereafter they were transferred to the GRI. A patient diagnosed with HCV infection while in adult care might have received the infective agent at either hospital, and under very different clinical regimes.

### **Royal Hospital for Sick Children, Yorkhill**

**21.291** Data on Haemophilia A therapy at Yorkhill are summarised in the Appendix to this chapter at Table 21.4, and shown graphically in Figure 21.9. The Figure has been prepared on the same basis as that for Edinburgh and south east Scotland.

**Figure 21.9: Glasgow Yorkhill Haemophilia A Therapy in Million International Units (Miu) – 1977–91**

**21.292** Data are available for Yorkhill from 1977 onwards. The UKHCDO has not reported any use of products up to 1976. Within the period for which data are available, there are variations that reflect changing policy. Cryoprecipitate use varied considerably until 1982, annual quantities ranging from 60 to 41,930 units without discernible pattern. Use of commercial products, already administered in 1977, rose steeply to 1981, fell back in 1982, and from 1983 dwindled to almost zero. 31,000 units of FEIBA were used, exceptionally, in 1991, but made no impression on Figure 21.9 in light of the high value for NHS products. The spike in 1988 reflects an exceptionally heavy use of NHS Factor VIII

concentrates, probably related to one or two unusual clinical events creating exceptional demand. There was no evidence that it reflected a change of policy.<sup>272</sup>

**21.293** Dr Willoughby, who was a haematologist at Yorkhill until the end of 1982, provided the Inquiry with two written statements.<sup>273</sup> He explained that commercial Factor VIII was used in order to make home therapy as easy as possible for the parents of his young patients. He wrote:

It was much easier to reconstitute with its diluent, taking only a few minutes of gentle handling, as I remember it. The volume for a normal dose could be comfortably drawn up into a 10 or 30ml syringe, which could then be easily attached to a slender scalp-vein IV needle for injection (rather than a drip-stand etc.).

Commercial factor products were typically supplied boxed with all the necessary components for immediate and easy use. The material was ordered through the hospital pharmacy and was relatively expensive, but it was considered that the advantages justified the expense.

**21.294** Dr Willoughby explained in his second statement that his prime concern was to treat haemorrhagic events as expeditiously as possible and home therapy avoided the need to travel, often some distance, to hospital. Dr Willoughby was an advocate of prophylactic therapy (see paragraph 21.113). In his statement he said that the aim of prophylactic home treatment was to prevent serious joint and muscle pathology, and to transform the children's quality of life and that of their families. Cryoprecipitate was unsuitable for home therapy due to the 'slow thawing out process in a 37 degree water bath, drip type infusion and somewhat uncertain dosage'.

**21.295** Although the risks of NANB Hepatitis were well known, Dr Willoughby's perception was that all concentrates carried a high risk of transmission, whether NHS or commercial. Pool size was less of a concern than using a product that permitted the establishment of a home therapy programme. Dr Willoughby thought that much more attention was paid to pool size following the discovery of HIV.

**21.296** Though scarcely discernible from Figure 21.9, cryoprecipitate was used at Yorkhill, but, both in absolute and relative terms, in very small quantities.

**21.297** As already indicated Dr Willoughby was a strong supporter of home therapy and of prophylaxis.<sup>274</sup> However, at Yorkhill, very young (and newly diagnosed) patients were usually managed as hospital-based patients (as opposed to home-therapy-based patients).<sup>275</sup> In general, Dr Willoughby considered that commercial and NHS concentrates had advantages over cryoprecipitate in that they could be stored at 4°C and could be carried by the patient when travelling.<sup>276</sup>

<sup>272</sup> The Inquiry contacted clinicians who worked at Yorkhill during the relevant period to see if they could recall the reason for the heavy use of concentrates in 1988. Professor Hann's response [PEN.019.1447], Dr Pettigrew's response [PEN.019.1450], Dr Gibson's response [PEN.019.1452]

<sup>274</sup> Paragraphs 21.95 and 21.113

<sup>275</sup> Professor Hann – Day 31, page 27

<sup>276</sup> Paragraph 21.96

**21.298** In his book on paediatric haematology, Dr Willoughby discussed the different products used to treat coagulation deficiencies. He noted that plasma and cryoprecipitate had an advantage over human concentrates in carrying a low risk of transmitting serum hepatitis since each bag was prepared from a single donor, rather than a pool. He noted that commercial Factor VIII and Factor IX concentrates were available as well as similar concentrates being available from many of the UK blood transfusion centres. He commented on the high cost of commercial concentrates. There was nothing to suggest bias in favour of the commercial product.<sup>277</sup>

**21.299** At the UKHCDO meeting held in Glasgow on 30 September 1980, Dr Willoughby said that from his experience of working with children it was clear that using Factor VIII concentrates would give the possibility of non-crippled adults.<sup>278</sup> He clearly favoured use of concentrates. According to Professor Hann, in a statement provided to the Inquiry, Dr Willoughby '[H]ad what appeared to be a preference for commercially (as opposed to NHS-produced) products ....'<sup>279</sup>

**21.300** That preference is reflected in the data for the early years covered by Figure 21.9. In a discussion with Professor Hann just prior to his departure from Yorkhill, Dr Willoughby said that he was generally disillusioned with the health service throughout the UK and felt he had been let down with regard to supplies.<sup>280</sup> He said that commercial concentrate was a better option as it was available, and enabled doctors to treat patients with very severe or life-threatening bleeding without having to rely on cryoprecipitate which was extremely difficult to use in children. He felt that the Scottish concentrate suffered from being of very low purity, difficult to draw up, with significant wastage, and there were also other problems such as infusion-related reactions.

**21.301** Professor Hann became Director of the West of Scotland Children's Comprehensive Care Haemophilia Centre in January 1983, in succession to Dr Willoughby.<sup>281</sup> There was an immediate, and significant, change in treatment policy. So far as recorded, Dr Willoughby had used Travenol Hemofil Factor VIII in 1977 and 1978. Armour Factorate was used in each year from 1977 to 1984, with usage in 1983 falling to 7.6% of the level in 1982, and to just over 1% of the 1982 level in 1984. Professor Hann effectively withdrew commercial concentrates from use on taking up his appointment.

**21.302** Professor Hann did not share Dr Willoughby's preference. He explained that the NHS product was cheaper, and that the risk of transmitting viruses was perceived to be smaller because of the better donor pool. But, he added, there were several caveats to that. One of these was the desire not to 'chop and change' products too much because of the small risk of inhibitor development which could be devastating as it made the patient untreatable in that era. For Professor Hann, the prime reason for choosing NHS product was the lower risk of infectivity.<sup>282</sup> However, he considered that, having discussed the issue with Dr Willoughby, his predecessor made the choice for what he regarded as good reasons. His evidence to that effect is accepted. Dr Willoughby justified his position in discussion with Professor Hann, and there is no evidence that undermines his position. Similarly, Professor Hann did not at that time share Dr Willoughby's belief that prophylaxis

<sup>281</sup> Professor Hann's statement on the use of blood product concentrates [PEN.012.0203]

<sup>282</sup> Professor Hann – Day 31, pages 80–82

was the way ahead. When he took over, he shared the scepticism, common at the time, as to the efficacy and practicality of prophylaxis. He now considered that Dr Willoughby was right.<sup>283</sup>

**21.303** Professor Hann said that he and Dr Willoughby discussed the question of supplies from the USA, which had been affected by Hepatitis B.<sup>284</sup> Dr Willoughby's view was that the problem of Hepatitis B had largely been overcome. It was also Professor Hann's experience at that time that they were not seeing new cases. Dr Willoughby felt that in the very early 1980s NANB Hepatitis was a minor disorder, and that all products were susceptible to it. The evidence rehearsed in this chapter indicates that there was a body of professional opinion supporting that position. Professor Hann commented that the Royal Free Hospital in London (a major hepatitis centre) also thought NANB Hepatitis was a minor disorder at that time.<sup>285</sup>

**21.304** Professor Hann said that he and Dr Willoughby agreed that there needed to be a move within the NHS to self-sufficiency. Professor Hann would have preferred to be able to use NHS concentrate, but it was not possible then to use Scottish product exclusively: there were periods when they had to call in extra commercial products.<sup>286</sup> Whether that was a sustainable position is less easy to determine. When asked whether a clinician could have felt that there was not a reliable enough supply of Factor VIII coming through around 1979–80, Dr Foster of the PFC replied that he did not know how well informed clinicians were about the stock situation. From his own analysis there was not a sustained problem.<sup>287</sup>

**21.305** When Professor Hann took over, treatment policy was reassessed, and in some respects took a new direction. Very young and new patients were still treated in hospital. They would be offered cryoprecipitate treatment in the first instance if it was possible logistically to give it to them (that is, if their veins were adequate and they did not have any reactions). As a result there was a sustained but relatively low level use of cryoprecipitate in the period 1983–87, as shown in the Appendix at Table 21.4.

**21.306** Professor Hann said that cryoprecipitate treatment may have even been recommended as the first option for his patients in the difficult interim period in 1984 when the HTLV-III virus had been isolated, and some of the patients were found to have antibody to the virus upon testing.<sup>288</sup> When asked whether he would have offered a child who was already receiving Factor VIII concentrate in late 1983 the possibility of ceasing concentrate therapy and returning to cryoprecipitate, he said that he believed that was what they had in fact done at Yorkhill.<sup>289</sup> He was almost certain that in late 1983, when 'people like Peter Jones and others' were suggesting that children could be treated with cryoprecipitate, he did change some patients over to cryoprecipitate and continued others for longer than he would have done previously.<sup>290</sup> Some patients returned to cryoprecipitate treatment in 1984 for a period of time.<sup>291</sup> His oral evidence is supported by the numerical data. However, he stressed that it was not a matter of automatically switching every child over to cryoprecipitate. The decision had to be tailored to each individual patient.<sup>292</sup>

### Glasgow Royal Infirmary

**21.307** Following the same approach as above, data on Haemophilia A therapy at the GRI are summarised in the Appendix to this chapter at Table 21.5, and shown graphically in Figure 21.10. The Figure has been prepared on the same basis as in the case of Edinburgh and south east Scotland and Yorkhill.

**Figure 21.10: Glasgow Royal Infirmary Haemophilia A Therapy in Million International Units (Miu) – 1969–91**

**21.308** There are gaps in the data for 1971, 1972 and 1973, but these do not appear to be material to a general understanding of trends in product selection over the material part of the period covered.

**21.309** So far as it is possible to draw inferences about the early years, it appears that cryoprecipitate use peaked in 1975 and then fell progressively until 1982. There followed a slow upward trend until 1985, and thereafter a reduction in use until 1989. No cryoprecipitate was used in 1990 and 1991. Use of SNBTS Factor VIII concentrates began in 1975, more or less coinciding with the commissioning of the PFC at Liberton, and thereafter increased progressively until 1988. In the final three years of the period use fell and commercial products became a more significant factor. In this last respect there is a close parallel with Edinburgh and south east Scotland. Purity had become an issue and the commercial product had an added attraction.

**21.310** In contrast to Edinburgh and south east Scotland, the data show measurable usage of commercial products before 1980, reaching a peak of just over 28% of Factor VIII concentrate use in 1979. Between then and 1987 there is no discernible pattern in the use of commercial products, either in absolute terms or in relation to total concentrate use.

**21.311** The commercial products used varied. Human Factor VIII plasma products in the period to 1980 included Kryobulin, Hemofil, Profilate, Factorate and Humanate. Koate entered the picture in 1981 and 1982. Otherwise, from 1981 until 1984, Factorate, Humanate, and Hemofil appeared without discernible pattern. From 1985 onwards, Porcine Factor VIII was prescribed. Use of commercial human plasma products began again in 1988, and included Profilate, Kryobulin, Monoclata, and Haemate P. The detailed data in Table 21.5 include limited use of DDAVP in 1978, 1980, 1981 and more consistent use from 1985 to 1991.

**21.312** In view of the somewhat confused picture painted by the numerical data, it would have been helpful to have had a clear explanation of policy from the senior consultants in charge of patient care. Professor Forbes started to work with haemophilia patients in the GRI in 1965, initially under Professor Douglas, and then as Haemophilia Director. However, he candidly told the Inquiry that after forty years he found it quite difficult to remember the details of what he thought at any one time and that his memory was ‘not as good now as it was all those years ago’.<sup>293</sup> According to his recollection, the policy for treating bleeding, from an early date, was the use of pooled cryoprecipitate. Cryoprecipitate was preferred because, being locally harvested, it carried a lower risk of transmitting hepatitis than ‘concentrates which were made with indeterminate but huge numbers of patients’ plasma being pooled together’.<sup>294</sup> The policy continued for many years. Patients with mild disease received DDAVP, but with caution because of its long-term side-effects.

**21.313** Professor Forbes’ evidence on product choice was that he continued to use cryoprecipitate for both routine treatment in the centre and for distribution to people on home therapy. He said:

[I]n reality, we had to give them what we could and they had to accept that that was what was available. They had to be pretty intelligent to use it correctly and effectively and make it up themselves, and I think that that was a limiting factor.<sup>295</sup>

**21.314** Professor Forbes had reservations about the use of DDAVP.<sup>296</sup> It caused changes in blood pressure and fluid retention.<sup>297</sup> For patients at the GRI, he had made efforts to provide cryoprecipitate from small pools for mildly affected patients and those on home therapy.<sup>298</sup> However, he repeated that cryoprecipitate was used because it was available from the SNBTS. But, there was concern about the efficacy and safety of concentrates made in Scotland and so the preference was still for cryoprecipitate.<sup>299</sup>

**21.315** The supply position caused Professor Forbes concern. As described by him, SNBTS’s ability to service demand was in stark contrast to the picture painted by Mr Watt and Professor Ronald Girdwood. Professor Forbes thought that any suggestion that Scotland was virtually self-sufficient in Factor VIII was ‘cloud-cuckoo land’: he did not think Scotland was ever self-sufficient in quality Factor VIII at that time.<sup>300</sup> In his view self-sufficiency meant that:

<sup>293</sup> Professor Forbes’ statement on information given to patients [PEN.012.0411] at 0415

<sup>297</sup> Professor Forbes – Day 17, page 114

<sup>298</sup> Ibid page 116

<sup>299</sup> Ibid page 105

<sup>300</sup> Ibid page 113

[A]t the drop of a hat, at any moment of time, if a patient required treatment, you could go to your people and say, 'We need to treat this patient, we need X, Y and Z,' that it would be available ....<sup>301</sup>

**21.316** However, it became clear that his requirement related to a combination of volume of supplies and quality. He said of the Factor VIII he wanted:

I mean stuff that you could rely on as to what it said on the bottle was actually in the bottle. So potent, effective therapy was the difficulty because there was such variation. So every time we gave a material, we measured it in the blood of the patient to ensure that there was enough to make them safe for whatever the procedure was. So if they were having major surgery, we would work out the dose required, we would give it and then we would check by a blood test after 20 minutes or so that we had achieved a haemostatic level of the Factor VIII or IX .... [If not] we would give another dose.<sup>302</sup>

**21.317** Professor Forbes confirmed that it was not a case of saying: 'The NHS Factor VIII isn't working, we had better get some commercial stuff'. Treatment would be continued with the NHS product.<sup>303</sup> He appeared to accept, subject to his reservations about consistency of Factor VIII efficiency, that there was enough product for routine treatment of patients in 1983. However, there was apprehension that there might be shortages if there had been a major car accident or major trauma, or a bleed into the brain.<sup>304</sup>

**21.318** Understandably, given the procurement role of the SNBTS at the GRI, Professor Forbes was not familiar with the supply position for Scotland as a whole. When he was shown Dr Donald Hopkins' letter to Dr Robert Crawford dated 4 December 1984<sup>305</sup> concerning the disposal of surplus SNBTS stock, he said he did not remember Dr Hopkins.<sup>306</sup> He did not know what the overall supply position was in Scotland relative to demand.

**21.319** In relation to the period discussed in this chapter, he said that he was not involved in procuring concentrates.<sup>307</sup> His department had no funds, and they 'used what was available'.<sup>308</sup> The system in Glasgow, as he described it, was that when clinicians 'wanted something to give', they had to approach Blood Transfusion, which then ordered it, and then it would depend on what deal they could make with the various companies.<sup>309</sup> The SNBTS had a unit embedded in the GRI, and it was the responsibility of the doctor in charge of that unit to decide whether to acquire commercial materials. Professor Forbes said that he had no idea how decisions on the purchase of commercial material were made.<sup>310</sup> As a clinician, he only knew whether he had commercial or NHS material available when it arrived in the ward and he was about to administer it.<sup>311</sup> On his evidence, if it is accepted as accurate, the SNBTS had, at least, a significant influence on the use of therapeutic materials. The prescribing clinician had no role in product choice. As Professor Forbes himself frankly admitted, it is unlikely that his recollection is completely reliable. In any

event, it is reasonably clear from UKHCDO data that use of commercial material in the GRI up to about 1984 involved a wide range of products from different manufacturers, at least consistent with sourcing according to market conditions rather than clinical assessment of the relative qualities of the products and the risks to patients.

**21.320** Due to the dimming of recollection with the passage of time, Professor Forbes' evidence cannot be accepted as a comprehensive, or sufficient, explanation of the position. It is clear that following the commissioning of the PFC at Liberton, the most significant therapeutic product prescribed was not cryoprecipitate but SNBTS Factor VIII concentrate. And his evidence does not explain the use of commercial concentrate, nor does it provide an explanation of the recorded use of DDAVP.

**21.321** Professor Lowe's evidence reflected more clearly the position in Figure 21.10. He told the Inquiry that factor concentrates had been introduced to the Glasgow Haemophilia Centre and increasingly used from the 1970s. However, there was a small amount of cryoprecipitate prescribed for patients with moderate severity Haemophilia A and von Willebrand's disease throughout the 1980s. This was because of the smaller blood donor pool and hence lower risk of hepatitis and HIV infection. The policy of the Directors at the time, as with many other haemophilia centres, was to keep cryoprecipitate and use it preferentially in patients who less frequently required treatment.<sup>312</sup>

**21.322** This policy continued until the UK Haemophilia Centre Directors guidelines on choice of blood products in May 1988 recommended that cryoprecipitate no longer be used for such treatment, unless the haemostatic efficacy of factor concentrates for treatment of von Willebrand's disease was in doubt.<sup>313</sup>

**21.323** Professor Lowe's recollection was that from about 1980 the Directors' policy was to treat patients with mild Haemophilia A preferentially with desmopressin (DDAVP), where appropriate and tolerated, or cryoprecipitate. Patients with mild Haemophilia B were treated preferentially with fresh frozen plasma.<sup>314</sup>

*Aberdeen*

**21.324** Numerical data for Aberdeen are set out in the Appendix to this chapter at Table 21.6. Graphically, the picture that emerges is shown in Figure 21.11.

**Figure 21.11: Aberdeen Haemophilia A Therapy in Million International Units (Miu) – 1969–91**

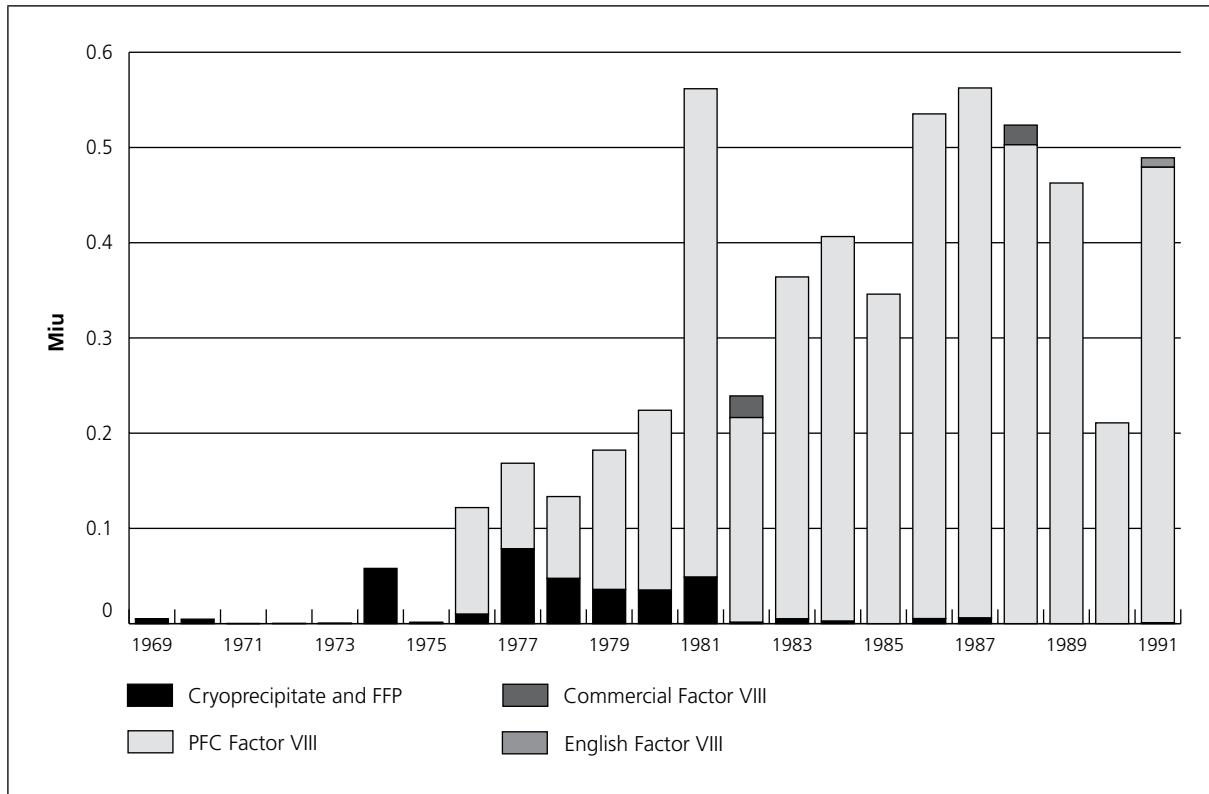

**21.325** The most noticeable feature of Figure 21.11 is the use of FEIBA for patients with inhibitors to Factor VIII concentrate, which provides a clear example of the adaptation of clinical practice to the perceived needs of specific patients. Otherwise, commercial product use was minimal and sporadic. In 1988 a relatively small quantity of Profilate was used, but there was no shift to greater use of commercial products generally such as occurred in Edinburgh and Glasgow. Cryoprecipitate use was inconsistent. It was initially displaced by use of SNBTS Factor VIII in 1976 after the PFC came on stream, but regained ground from then until 1980, after which use fell away until about 1985. For the next three years there was a small increase in cryoprecipitate use, but the PFC Factor VIII remained the dominant product throughout the period from 1981. Leaving aside the specific use of FEIBA, treatment policy at Aberdeen was clearly to use SNBTS products.

*Dundee*

**21.326** Numerical data for Dundee are set out in the Appendix to this chapter at Table 21.7. Graphically, the picture that emerges is shown in Figure 21.12.

**Figure 21.12: Dundee Haemophilia A Therapy in Million International Units (Miu) – 1969–91**

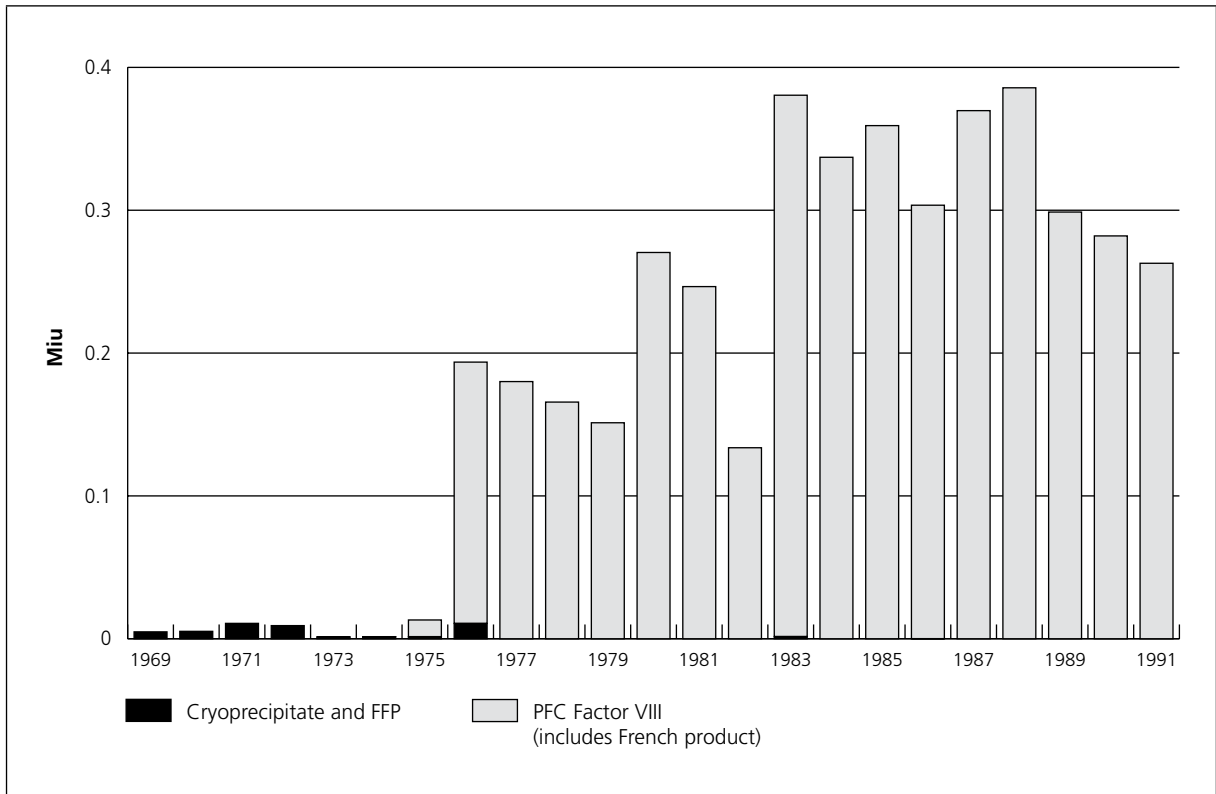

**21.327** Two small quantities of commercial material were purchased in 1982 (Porcine Factor VIII) and 1988 (Profilate). The 1988 transaction was a close parallel to Aberdeen's use of commercial human plasma Factor VIII in that year. A very small quantity of the BPL 8Y was used in 1991. Otherwise, treatment policy was consistently to use SNBTS products, predominantly Factor VIII concentrate after the PFC came on stream.

*Inverness*

**21.328** Numerical data for Inverness are set out in the Appendix to this chapter at Table 21.8. Graphically, the picture that emerges is shown in Figure 21.13.

**Figure 21.13: Inverness Haemophilia A Therapy in Million International Units (Miu) – 1969–91**

**21.329** Inverness used a tiny quantity of Hemofil in 1974. It is irrelevant to the pattern of use in the centre. The same comment can be made in relation to DDAVP. Small quantities were used from 1986 to 1991, but do not impact on the picture overall. From the commissioning of the PFC, Inverness used SNBTS Factor VIII almost exclusively.

**21.330** In relation to product choice and use, there is a clear distinction between the Glasgow and Edinburgh centres on the one hand and Aberdeen, Dundee and Inverness on the other. Practice in the three smaller centres involved far less use of commercial materials, and perhaps reflected most clearly the implementation of government, and SNBTS, policy that haemophilia treatment should be on a self-sufficient basis using domestic products other than in exceptional cases.

**21.331** Since various commercial products have been mentioned, it is perhaps worth noting their relative impacts on the UK market, as illustrated for 1980 and 1981:<sup>315</sup>

Manufacturer	Trade Name	International Units	
		1980	1981
Abbott	Profilate	1,649,000	1,909,000
Armour	Factorate	16,576,000	14,646,000
Cutter	Koate	4,935,000	3,823,000
Hyland	Hemofil	5,095,000	*5,554,000
Immuno	Kryobulin	5,377,000	7,377,000
Speywood	Humanate	615,000	1,561,000
Hyland	Interhem	502,000	
<b>TOTAL</b>		<b>34,749,000</b>	<b>34,870,000</b>

\*Includes Interhem

**21.332** Armour's Factorate was the most used product, with Hemofil, Kryobulin and Koate following. Relative to Scottish use, Abbott's Profilate might have been expected to have had a higher profile.

**21.333** The Inquiry has not investigated the issue of choice of product in England and Wales. That was not required by the Terms of Reference.

## Discussion

**21.334** Turning to the wider issues raised in respect of this period, it is clear that considerable advances had been made in the treatment of haemophilia. Patients' lives had been transformed by the new products which became widely available in the 1970s. In particular, the arrival of concentrates led to an overwhelming improvement in quality of life, especially for those with severe haemophilia.

**21.335** Although there was awareness that there were risks associated with concentrates, primarily the risk of contracting hepatitis, the natural history of hepatic disease was not well understood by 1981. As discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*, there remained substantial deficits in knowledge of NANB Hepatitis and its natural history well into 1985. The seventh edition of Professor Sheila Sherlock's book *Diseases of the Liver and Biliary System* dated October 1985 noted that there was increasing concern 'in some quarters' about the potential seriousness of NANB Hepatitis. As at 1981, both clinicians and the haemophilia population in general considered that the life-enhancing benefits of concentrates far outweighed any perceived risks. As the 1970s progressed, more and more evidence had emerged reinforcing the risk of acquiring hepatitis, but with the exception of a few reported cases of serious illness and a very few fatal cases, hepatitis was not reported to be associated with serious outcomes.

**21.336** With the publications of Mannucci et al, and of the proceedings at the World Federation of Hemophilia and the International Society of Blood Transfusion symposium in Helsinki, the dilemma facing clinicians over the use of concentrates became more pronounced. Professor Forbes' evidence that the 'possible downside' of concentrate use was known, but the risk of death from bleeding was greater and drove clinicians to use the products is accepted. It was to the same effect as Dr Craske's views, reported in *The Lancet* of August 1975, relating to the balance of risk and benefit in the use of Hemofil.

<sup>315</sup> Department of Health table showing quantities of Factor VIII concentrate used in the UK, 1980 and 1981 [DHF.001.4517]

**21.337** From the point of view of Dr Craske and his colleagues in public health, reducing risk was a factor examined in their recommendations: use of commercial concentrates should be restricted to life-threatening situations and to major surgery. Until the end of the period of Dr Craske's surveys for the UKHCDO in 1982–83, their reports acknowledged the possibility of a non-B Hepatitis that was not Hepatitis A, but did not attempt to attribute specific risk to NANB Hepatitis, and as a result, Dr Winter noted, the recommendation to reserve commercial concentrates for severely affected haemophiliacs was based on irrelevant reasoning. A more cogent reason would have been that regularly treated patients with severe haemophilia would almost certainly have already acquired NANB Hepatitis, distinguishing them from new and infrequently treated patients. But that had not yet been realised. It was at the very end of this period that an association with NANB Hepatitis was specifically acknowledged. It would not be appropriate to conclude that Dr Craske's views would, or should, have carried particular weight at this point. Rather, they illustrate continuing confusion over the nature of the hepatitis risk that was only gradually being resolved.

**21.338** That confusion was apparent in the comments made in the 'World in Action' programme of 8 December 1975. The differences between Dr Maycock and Professor Zuckerman showed that professional opinion in the UK had not resolved a common position on the risks associated with large-pool factor concentrates. The ambition to remove risk by increasing manufacturing capacity in the public sector to self-sufficiency, in retrospect, illustrated the depth of misunderstanding of the risk of NANB Hepatitis transmission. Dr Winter's interpretation of the discussion in the programme is accepted: in retrospect it was about Hepatitis B. Although NANB Hepatitis had been postulated in 1974, it had not made the impact on professional thinking that would begin to be seen in the early 1980s.

**21.339** It is not appropriate to accept Dr Winter's evidence that the discussion 'should' have been about NANB Hepatitis in the circumstances, except in the sense that, with the benefit of hindsight, that was the real issue for patients. But it was not known to be the issue at the time. Professor Zuckerman could still talk of 'hepatitis or jaundice' being a particularly interesting infection as if the terms were synonymous. What is clear from the programme is that the clinical dilemma continued to be whether to accept the risk of serious morbidity and mortality associated with bleeding, or accept the risks associated with hepatitis, as they were understood at the time. Dr Winter's observations on the contribution of the patient who was on the point of discontinuing the use of Hemofil when he had a bleed in his elbow and sought immediate relief by using the preparation was eloquent of the problem. There was no settled view from haemophilia experts about the risk of hepatitis: the effects of haemophilia were only too clear to the patient.

**21.340** The 1975 programmes would have made an impression on any interested viewer. They clearly did affect the perception of clinicians. Professor Forbes' evidence of the reaction of haemophilia clinicians demonstrated that clearly. But it was the sensational aspect of the television programmes that struck home: the lines of people with alcohol, and other disadvantaged people, queuing to give blood. As Dr Winter noted, that was fundamentally irrelevant. The fact that they took alcohol did not prove their viral status. The technical discussion, for example the difference between Dr Maycock's and Professor Zuckerman's views, would not have added materially to the general understanding among clinicians of the fundamental nature of the problem of transmission of infection.

**21.341** Dr Craske's ongoing study of infection following infusion of commercial products is instructive. His report to the UKHCDO on 13 January 1977, comparing NHS and commercial Factor VIII, continued to focus on jaundice. Dr Biggs reported data returned from haemophilia centres on the incidence of jaundice. Professor Stewart's somewhat dismissive comments indicated that, for some haemophilia specialists, the risk of jaundice was something one simply had to live with.

**21.342** It was not until the early 1980s that there was a growing realisation that, while the risk of Hepatitis B was declining markedly due to constant improvements in screening blood donors for evidence of Hepatitis B infectivity, there was a new form of hepatitis (NANB Hepatitis). Little was known about the likely progression of this new illness, but by 1981 it was known to be very common among haemophilia patients treated with concentrates. As discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975–1985*, it was not until 1984–85 that the natural history of NANB Hepatitis was beginning to be understood to involve a risk of serious long-term progressive liver disease with significant morbidity and mortality.

**21.343** Despite these acknowledged risks, there was no desire in the haemophilia community to revert to the pre-concentrate era. While cryoprecipitate was seen as less risky in terms of hepatitis transmission, there were too many disadvantages associated with its use. It was hoped that improved screening methods would lead to the eradication of hepatitis and other impurities in blood products. However, at the end of this period, about 1982–83, an unidentified virus was beginning to emerge that would transform the lives of the haemophilia population once again. This new virus, later identified as HIV, and the link with concentrates (particularly commercial in origin) was to have a devastating impact on the haemophilia population in the 1980s.

**21.344** Until that happened, haemophilia therapy continued to depend largely on concentrates, and the demand for the products increased.

**21.345** This chapter has touched on the preparation and supply of NHS blood and blood products, but has been concerned mainly with the second of the two relevant Terms of Reference noted at the beginning of the chapter:

8. To investigate the steps taken by those involved in, and those responsible for, the NHS in Scotland including NHS boards and SNBTS, their officers and employees and associated agencies, to prevent the provision of infected blood and blood products.

**21.346** There was considerable work done in the 1970s and early 1980s to identify and defer blood donations that were found to be infected with HBV and other viral conditions on routine testing with the best assays available from time to time. This is discussed in Chapter 25, *Screening of Donated Blood for Hepatitis B*. Steps taken to treat therapeutic products to eliminate or reduce the risk of transmission of viral infection are discussed in Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*. The technology developed and applied was targeted at the pathogens that were either known or postulated, with a degree of confidence, to be likely to be found in components of, and in products produced from, human blood. Nothing was done to prevent the provision of blood and blood products infected with the viruses that are of central importance in this Inquiry: NANB Hepatitis/HCV in the 1970s and early 1980s or, when it emerged, HTLV-III/HIV.

**21.347** Incidentally, technology developed to deal with known pathogens came to have significance in relation to identification of materials infected by one or other of these viruses or to inactivation of infection in blood products. However, there was nothing that could have been done to prevent the provision of blood and blood products infected with NANB Hepatitis in the period covered by this chapter. Firstly, and most importantly, there was no possibility of detection of the virus until it (or they) had been identified. Until HCV was partially isolated and characterised in 1988, it was speculated that there might be more than one pathogen causing hepatitis that was neither Hepatitis A nor Hepatitis B. HTLV-III/HIV was not known at all until 1982. Whole blood and the cellular components of blood for transfusion benefited from screening, but could not be treated to activate any virus in the materials.

**21.348** Moreover, both before and after the licensing of commercial Factor VIII for general prescription, the choice of therapeutic material was a matter of judgement for individual clinicians in relation to the needs of particular patients. Commercial products were administered in 1972, necessarily on a named patient basis, since they were not then licensed. After they were licensed, from 1983 onwards, clinicians were free to prescribe and use them more generally. Interference with clinical judgement at the point of treatment of the patient would have been considered to be a breach of the clinical autonomy of the practitioner.

**21.349** The NHS in Scotland could not have restricted the import and use of commercial products once they were licensed. Licensing was a function of the UK Government. NHS Boards were not in a position to make any contribution in this area.

**21.350** From 1974, the operational responsibility for the provision of human blood for transfusion and for the production of blood products had been delegated by the Secretary of State for Scotland to the CSA, subject always to such directions as the Secretary of State might give. As discussed in Chapter 17, *Blood and Blood Products Management*, the CSA did not exercise operational control over the delivery of the blood transfusion service, and regional and national managers had largely autonomous control of their respective operations. Blood transfusion directors asserted and were allowed a degree of operational autonomy comparable to that of clinicians.

**21.351** Scotland was in a particularly favourable position in respect that production capacity was sufficient in general to meet demand for NHS product. In the late 1970s, into early 1980s, demand outstripped supply briefly. But the continuing increase in demand for NHS products over the period was dramatic.

**21.352** In this period, all human plasma products, including cryoprecipitate, exposed haemophilia patients to the risk of transmission of NANB Hepatitis/Hepatitis C.

**21.353** So far as NHS products are concerned, they were perceived by most practitioners to be preferable to imported products, being prepared from local blood donations, and less likely to transmit infection. Promotion of their use was the obvious policy position to adopt over this period. That they turned out to be infective, though, at least in relation to HCV, less so than imported products, would only have been a basis for intervention if those responsible for the decision had been prepared to prohibit their use, and expose patients to the known risks of morbidity and mortality associated with haemophilia that had existed prior to 1973. That was never likely to happen, and would in any event have been strenuously resisted by patients and patient groups. The inexorable increase

in demand over this period shows the commitment of clinicians and patients alike to concentrate therapy.

**21.354** Looking to the factors that generated increasing demand for concentrates, home treatment and prophylaxis were clearly contributory factors, especially the first. Home treatment enabled people with haemophilia to lead a more normal life, but exposed patients to a greater amount of product than would have been used in purely reactive therapy. Exposure to commercial concentrate, where there was a lack of NHS product, led to greater exposure to transmission of viruses. The evidence as a whole demonstrated that home treatment was to the overwhelming advantage of the haemophilia population. It enabled the speedy and effective treatment of bleeds by the patients or their families who were trained in recognition of the symptoms of a bleed, and in the administration of therapy. That was preferable to the risks of inappropriate treatment in a hospital accident and emergency department with all the associated problems that involved, as described in the evidence.

**21.355** Could the NHS have intervened to prevent the introduction and expansion of home treatment? Again it would have involved an interference with clinical autonomy at the doctor-patient interface. It would not have been acceptable, and given the state of knowledge of the long-term risks associated with factor therapy at this time, it would have been wrong.

**21.356** Where prophylaxis was introduced, it might have exposed patients to substantially more product than on-demand treatment. But it prevented spontaneous bleeds, for example cerebral bleeds which used to be the most common cause of death for people with haemophilia, and it reduced joint damage and crippling, resulting in less pain in later life and a better quality of life for the patient.

**21.357** In this, as in most areas, it is superficially easy to ask, with the benefit of hindsight, whether all developments should have been held up until research had established that products and procedures were 'safe' in some absolute sense. However, safety is never absolute: it is always relative to some reference point in current knowledge. The manufacturers who promoted the use of early concentrates did not do so in the knowledge that they were 'unsafe'. They were conscious of the risks of 'hepatitis', as the risks were understood from time to time. But those risks were thought to be acceptable given the benefits of therapy. These subjects were discussed, researched and reported. In the final analysis, all concerned; manufacturers, haemophilia clinicians, patients, and the Haemophilia Society, wanted to carry on treatment with concentrate despite the risks rather than reverting to cryoprecipitate, because of the benefits they saw and experienced.

## Conclusions

- There was no evidence before the Inquiry that would support a finding that Scottish practitioners were influenced in their choice of therapeutic products by benefits provided by pharmaceutical companies.
- There was considerable work done in the 1970s and early 1980s to identify and defer blood infected with HBV and other viral conditions.
- Nothing could have been done to prevent the provision of blood and blood products infected with NANB Hepatitis in the 1970s and early 1980s or, when it emerged, HTLV-III/HIV. There was no possibility of detection of either virus until each had been identified (HIV in 1983–84 and HCV in 1988–89).
- Both before and after the licensing of commercial Factor VIII for general prescription, the choice of therapeutic material was a matter of clinical judgement. Commercial products were administered in 1972, necessarily on a named patient basis, since they were not licensed. After they were licensed, clinicians were free to prescribe and use them more generally. Interference with clinical judgement at the point of treatment of the patient would have been considered to be a breach of the clinical autonomy of the practitioner.
- The NHS in Scotland could not have restricted the import and use of commercial products once they were licensed. That was a function of the UK Government.
- There is no criticism that can legitimately be made of practice in relation to the use of factor concentrates over this period. Change was beginning. DDAVP had been recommended for mild haemophilia. Biopsy investigations had indicated a risk of more severe liver damage than had been anticipated. But the general body of medical opinion remained favourable to the continued use of concentrates. It would have been quite unrealistic for the NHS in Scotland to have promoted a different approach by the end of 1982.

## Appendix to Chapter 21

## CHAPTER 22

### HAEMOPHILIA THERAPY – USE OF BLOOD PRODUCTS 1985–1987

#### Introduction

**22.1** This chapter deals primarily with the treatment of patients with Haemophilia A following the introduction in Scotland in December 1984 of heat treatment of blood products.<sup>1</sup> The initial heat treatment protocol for Factor VIII was effective against HIV, but it was suspected, and later confirmed, that concentrates produced by the Protein Fractionation Centre (PFC) in Edinburgh and subjected to heat treatment continued to transmit Hepatitis C (HCV), then known as non-A non-B Hepatitis (NANB Hepatitis). That remained the case until the introduction of Z8, a heat-treated concentrate produced at the PFC and subjected to more rigorous heat treatment than its predecessor, NY. Z8 was issued to patients in Scotland from April 1987.<sup>2</sup>

**22.2** Difficult decisions in the treatment of patients with Haemophilia A therefore required to be made during the period 1985–87. For some patients in some situations, blood product therapy for haemophilia was unavoidable. But it was becoming increasingly clear that NANB Hepatitis was a potentially serious disease.<sup>3</sup> By this time, it had become clear that the use of Factor VIII therapy carrying a high risk of transmission of NANB Hepatitis was a decision to be taken only with the greatest care. This was especially so where the patient had never previously been treated with blood products and could, therefore, be assumed to be free from NANB Hepatitis. Virally inactivated Factor IX for the treatment of Haemophilia B patients was introduced in October 1985.<sup>4</sup> The period during which options on treatment presented particular problems for these patients was therefore shorter.

**22.3** Correspondence referred to in the Inquiry's Preliminary Report indicated that during the period 1 September 1985 to 30 June 1987 a total of 31 people in Scotland were treated for the first time with a blood product, either Factor VIII or Factor IX according to their index condition.<sup>5</sup> This information was provided for the purposes of a Scottish Executive Health Department (SEHD) Inquiry in 2000. The report of that inquiry stated that fewer than 10 of those people had tested HCV positive, although the status of a small number was unknown.<sup>6</sup> A further letter, dated 17 March 2000 (which was not available when the Preliminary Report was prepared) indicates that 29 patients were first treated between September 1985 and December 1987.<sup>7</sup> The Inquiry is not able to explain the reduction from 31 to 29, over a longer reference period, but it may be that there had been double counting in the earlier figure.<sup>8</sup> As indicated in Chapter 3, *Statistics*, this was a common problem arising from the registration of patients at more than one centre. Of the 29, six – all Haemophilia A patients – tested positive for HCV. The status of 14 patients (with Haemophilia A or B, von Willebrand's disease, or, in one case a Haemophilia B carrier) was not known. Most patients included in these figures will have been children when treated.<sup>9</sup>

<sup>1</sup> Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*, at paragraph 23.192.

<sup>2</sup> Chapter 24, *Viral Inactivation of Blood Products for Haemophilia Therapy 1985–1987*, paragraph 24.157.

<sup>3</sup> Chapters 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*, and 16, *Knowledge of Viral Hepatitis 3 – 1986 Onwards*.

<sup>4</sup> Chapter 24, *Viral Inactivation of Blood Products for Haemophilia Therapy 1985–1987*, paragraph 24.67.

<sup>5</sup> Paragraph 9.326 of the Preliminary Report, drawing on information from the notes of a meeting held on 10 February 2000 [SGH.002.1597]

<sup>6</sup> Report of Scottish Executive Inquiry, 2000 [SGH.001.4414] at 4419. From [SGH.002.1597], the number testing positive appears to be eight.

<sup>7</sup> Letter from Dr Cachia to Dr Keel, 17 March 2000 [PEN.018.1483] at 1485

<sup>8</sup> The possibility of double counting was mentioned at the meeting on 10 February 2000 [SGH.002.1597] at 1597

<sup>9</sup> Professor Lowe – Day 54, page 60

**22.4** As referred to in paragraph 22.76, the Inquiry is directly aware of the circumstances of two such individuals. It does not have data for how many people might have been infected in the period December 1984 to September 1985. The SEHD chose September 1985 as the start date for the period of its investigation by reference to the point when the Blood Products Laboratory (BPL) in England was issuing a ‘hepatitis safe’ product, 8Y. The Inquiry selected December 1984 as the start of the period for its examination of this topic because that was when an ‘HIV safe’ product was available from the PFC in Edinburgh and the focus thereafter shifted back to the risk of transmitting NANB Hepatitis.<sup>10</sup>

**22.5** How treatment decisions were made during the relevant period, and the steps taken by clinicians to avoid the infection of patients with NANB Hepatitis, are matters examined in detail in this chapter.

### Hearings of evidence

**22.6** When hearings began in March 2011, this topic had not been designated as one to be considered at Oral Hearings of the Inquiry. On 4 May 2011, during the questioning of Professor Ludlam in relation to haemophilia treatment when AIDS was the principal risk of concentrate therapy, it became apparent that there was a gap in the topics insofar as this aspect was concerned.<sup>11</sup> A draft of a proposed additional topic was prepared and circulated amongst the Core Participants. The addition of the topic was formally confirmed by the Chairman of the Inquiry, and it was introduced and evidence was first led on Day 54.

**22.7** The topic was expressed as follows:

The use of blood product concentrates in Scotland in the period between the introduction of NHS heat-treated products in 1984 and the supply of NHS products sufficiently treated to inactivate Hepatitis C.<sup>12</sup>

### December 1984 guidance for haemophilia clinicians

**22.8** The Haemophilia Reference Centre Directors met at the BPL at Elstree on 10 December 1984. The meeting was chaired by Professor Bloom, at that time chairman of the UKHCDO. ‘Factor VIII Concentrates’ was one of the items discussed. It was agreed that treatment options would vary depending on whether or not the patient was HIV antibody-positive. The minutes record:

It was agreed that HT [heat treated] product should be given to all patients, if freely available, to include those found to be antibody +ve. In the case of antibody –ve patients, it was agreed that from now on, treatment must be with HT material.<sup>13</sup>

....

It was agreed that priority for NHS HT material would be given to children and past users of NHS material.<sup>14</sup>

---

<sup>10</sup> The emergence of an understanding of the risk of NANB Hepatitis from concentrate therapy in the 1970s is dealt with in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975–1985*.

<sup>11</sup> Day 19, pages 121–122

<sup>12</sup> Day 54, pages 9–10

<sup>13</sup> Note of the Haemophilia Reference Centre Directors Meeting, 10 December 1984 [SNF.001.3850] at 3853

<sup>14</sup> Ibid [SNF.001.3850] at 3858

....

The Chairman advised that he would issue guidelines following the meeting. In summary, the first choice would be HT material followed by the judgement of the individual clinician.<sup>15</sup>

**22.9** Professor Bloom prepared and sent guidelines, dated 14 December 1984 and entitled *Haemophilia Centre Directors Organisation AIDS Advisory Document*. The document listed the following options for treatment:

Options in probable decreasing order of safety from AIDS for Haemophilia A

1. Heated U.K. concentrate (note: still NANB hepatitis risk)
2. Single donor cryo. or FFP
3. Heated imported conc. (note: still NANB hepatitis risk)
4. Unheated U.K. conc.
5. Unheated imported conc – almost certain to be contaminated.

Note: Heated concentrates may still transmit hepatitis. Some of the distinctions e.g. between 3 and 4 are debatable and the long-term effects (e.g. immunogenicity) of using heated plasma proteins in this way are unknown....

RECOMMENDATIONS

1. Concentrate is still needed; bleeding is the commonest cause of disability and death.
2. Use DDAVP in mild Haemophilia and vWd<sup>16</sup> if possible.
3. For Haemophilia A needing blood products
  - (a) “Virgin” Patients those not previously exposed to concentrate, and children use cryo or heated NHS factor VIII (if available).
  - (b) Severe and Moderate haemophiliacs previously treated with factor VIII use heat treated NHS factor VIII, if available or heat treated US commercial.
4. Haemophilia B
  - (a) Mild Christmas Fresh frozen plasma if possible (otherwise NHS Factor IX).
  - (b) “Virgin” Patients and those not previously exposed to concentrate, use fresh frozen plasma (or NHS factor IX concentrate if essential)
  - (c) Severe and Moderate Christmas Disease previously exposed to factor IX concentrate continue to use NHS factor IX.<sup>17</sup>

**22.10** Professor Lowe and Professor Ludlam were asked about this guidance and its application in their respective haemophilia centres in the course of their oral evidence. Professor Ludlam was at the meeting on 10 December, whereas Glasgow was represented at the meeting by Dr Forbes.

## *Glasgow*

**22.11** Professor Lowe told the Inquiry that treatment in Glasgow between the end of 1984 and 1986 reflected the guidance. He said:

[Practice in Glasgow was] very much in line with what you see there on the screen. The majority of our patients requiring factor concentrates were severe haemophiliacs. They had been treated for many years with Factor VIII concentrates. That was what they continued to have, and while patients could be told that the heat treatment was thought likely to reduce the risk of HIV, there was no evidence at the time that it would reduce the risk of non-A non-B Hepatitis. Hence, in patients who had not been previously exposed to concentrates, the desirability to try, as I have said, to limit the exposure to non-A non-B Hepatitis by considering the use of alternative products, cryoprecipitate or fresh-frozen plasma, according to individual circumstances.<sup>18</sup>

**22.12** He was pressed on what the choice would have been between cryoprecipitate and heated NHS concentrate, given that cryoprecipitate was not treated to inactivate HIV and NHS heated concentrate still carried a risk of NANB Hepatitis. He answered:

As I recall, the majority of our patients had the heated SNBTS Factor VIII concentrate. There were a small number of patients who had not previously received concentrate and for those, if one was particularly concerned about non-A non-B Hepatitis, then cryoprecipitate or FFP, for patients with Factor IX deficiency, might be preferable.<sup>19</sup>

**22.13** Professor Lowe said that Dr Forbes' policy had been very much to consider the individual patient. The introduction of screening of blood donations for HIV in October 1985 was an additional factor – cryoprecipitate was thereafter being made from donations which had been screened for HIV, improving its safety as a product. It was a period when the directors had to 'continuously weigh up what was happening'.<sup>20</sup>

**22.14** Greater detail was sought from Professor Lowe as to the type of patients who posed particular dilemmas at that time. He felt that the group of patients who would not have been on heated Factor VIII at that time was very small in number and would have been dealt with by Dr Forbes. He struggled to remember individual instances of this dilemma, and it is not possible to be confident that his evidence of discussions reflects only recollection, free from an element of reconstruction after the event. Subject to that, he thought that the sort of conversation which would have taken place with infrequently treated patients who had moderately severe haemophilia would have been along the following lines:

"Well, you know, there is a choice. You can have a product which, while heat-treated, the concentrate, it's coming from thousands of donors and there is no guarantee that you will not get an episode of non-A non-B Hepatitis, which you don't want."

---

<sup>18</sup> Professor Lowe – Day 54, page 17

<sup>19</sup> Ibid page 18

<sup>20</sup> Ibid page 19

He added:

And particularly after the introduction of HIV testing of blood donors, cryoprecipitate, you know, while it could still have a small risk of HIV, had a very good safety compared to concentrate, a reduced risk of getting hepatitis.<sup>21</sup>

**22.15** With von Willebrand's patients, there was an additional reason to prefer cryoprecipitate. If Factor VIII concentrate was used, the deficient von Willebrand Factor was not being replaced. Haemostasis was easier to achieve with cryoprecipitate than with concentrate.

**22.16** Professor Lowe was then asked to apply his mind to the sort of choices that had to be made with patients whose haemophilia was mild. He alluded to the involvement in decision-making of the patients themselves: [I]t was very much part of the unit's policy to recognise that there was a risk of hepatitis and to share that with the patients'.<sup>22</sup> For a patient with mild haemophilia, the first choice would be to use desmopressin (DDAVP).<sup>23</sup> He could not remember any patients with mild haemophilia or von Willebrand's disease who had to have a blood product during the 1985–87 period. Even for the patient with mild haemophilia having a bleed, desmopressin was usually effective, because the transient increase in Factor VIII was usually enough to stop the bleed.<sup>24</sup> Sometimes even the physiological response to bleeding, whereby the levels of Factor VIII rise naturally, was enough to deal with the problem in a person with mild haemophilia.<sup>25</sup> But, Professor Lowe explained in later questioning, in a patient with haemophilia desmopressin is generally less effective in response to bleeding which has already started than it is in preventing bleeding.<sup>26</sup> With a joint or muscle bleed, concentrate therapy was 'much more likely' to be required.<sup>27</sup>

**22.17** At that time, if a patient with mild haemophilia was having a major bleed, it would be necessary to discuss with him the use of concentrates and the risk of hepatitis. And even if cryoprecipitate were to be used, it would have been necessary to tell the patient that large doses over a period of days would also carry a risk of infection with NANB Hepatitis.<sup>28</sup> An average adult dose would use material from 20 donors.<sup>29</sup>

**22.18** Professor Lowe was then asked about the 'steer' which might have been given to such a patient by medical staff. After some deliberation, he answered that if patients had asked what he personally would do in their situation, he would have told them he would opt for treatment with cryoprecipitate from 20 donors who were HIV tested.<sup>30</sup>

<sup>21</sup> Ibid page 22

<sup>22</sup> Ibid page 24

<sup>23</sup> In later questioning, Professor Lowe agreed that desmopressin becomes less effective after about 48 to 72 hours of use, and that it has some drawbacks with children in particular, principally fluid retention. See Day 54, pages 67–68.

<sup>24</sup> Professor Lowe – Day 54, pages 25–26. Further discussion of the mechanisms involved in the use of desmopressin can be found in Professor Lowe's evidence at Day 54, pages 70–73.

<sup>25</sup> Professor Lowe – Day 54, page 26

<sup>26</sup> Ibid page 72

<sup>27</sup> Ibid page 73

<sup>28</sup> Ibid page 27. Professor Ludlam made the same point (see Day 54, pages 132–6): treatment with cryoprecipitate still carried a risk of NANB Hepatitis. Estimates given in evidence of the scale of the risk varied – plainly, this depended on the incidence of the virus in the donor population at the time. If the incidence was 0.4%, as it was found to be by Minor et al in their examination of donor samples ('Antibody to Hepatitis C virus in plasma pools', *The Lancet*, 21 July 1990 [SGF.001.1380]) then exposing a person to 250 donations in his life would be expected to cause infection. Professor Ludlam was more pessimistic, saying that an adult treated with cryoprecipitate for five days would 'almost certainly' contract NANB Hepatitis. See also Dr Colvin – Day 55, page 139. The incidence of Hepatitis C in the donor population is discussed more fully in Chapter 3, *Statistics*.

<sup>29</sup> Professor Ludlam – Day 54, page 136

<sup>30</sup> Professor Lowe – Day 54, page 30

**22.19** Considering the issue more generally, Professor Lowe agreed that there was a general desire among haemophilia treaters to avoid the use of concentrates at that time. The reasons for that were the awareness that initial heat treatment was not effective against NANB Hepatitis, which was ‘more or less inevitable if you got concentrate’ and the growing realisation that NANB Hepatitis was not, as had previously been thought, a ‘relatively benign disease’.<sup>31</sup> In answer to later questioning, he agreed that the dose likely to be required was also a factor because, if the patient were to be having daily cryoprecipitate for two weeks, the advantages of cryoprecipitate over concentrates would vanish because of the patient’s being exposed to several hundred donors.<sup>32</sup> For that reason, there was ‘more of an equipoise for a small number of patients between cryoprecipitate and concentrate’.<sup>33</sup>

**22.20** As far as Factor IX was concerned, it was decided in Glasgow in April 1985 to use commercial heat-treated product until the NHS heat-treated product became available in the autumn.

**22.21** There is no record of the English product, 8Y, being used in Glasgow over the period 1985–1987, and Professor Lowe did not recall any such use.<sup>34</sup> In response to more general questions about knowledge at the time of the development of 8Y, Professor Lowe had no memory of hearing informally about the advances in England,<sup>35</sup> or of anyone proposing that Glasgow could attempt to obtain a small supply of 8Y to treat particular patients.<sup>36</sup> By way of explanation for his unfamiliarity with the then current position in England, Professor Lowe said that, even once he had been appointed as a consultant, Dr Forbes had made it clear that he was running the haemophilia unit and Professor Lowe was his assistant. Professor Lowe was developing services in relation to thrombosis, rather than haemophilia.<sup>37</sup> He was anxious, however, to correct any impression that there was a lack of communication between himself and Dr Forbes.<sup>38</sup>

### *Edinburgh*

**22.22** Professor Ludlam agreed that in relation to the period under examination, it was fair to say that therapeutic policy was ‘guided by a desire to avoid the use of blood products unless there was no alternative’.<sup>39</sup> In his statement to the Inquiry, Professor Ludlam had said:

When [the first heat-treated product] NY 68 degree/2 hour, was introduced in December 1984 ... it was widely acknowledged that it was very likely to transmit non-A non-B hepatitis.<sup>40</sup>

**22.23** Later in his statement, Professor Ludlam informed the Inquiry that, during this period:

[I]n the majority of patients, the sole aim was to prevent HIV transmission and this was accomplished by using heat-treated concentrates, even although it

<sup>32</sup> Ibid pages 64–65

<sup>33</sup> Ibid page 66

<sup>34</sup> Ibid pages 40–41. UKHCDO data indicate that 8Y was first used in Glasgow Royal Infirmary and in Yorkhill in 1990.

<sup>35</sup> Ibid page 44

<sup>36</sup> Ibid page 46

<sup>37</sup> Ibid page 47

<sup>38</sup> Ibid pages 56–57

<sup>39</sup> Ibid page 74

<sup>40</sup> Professor Ludlam’s statement on the use of blood product concentrates between 1984 and 1987 [PEN.017.1790]

was thought likely that they transmitted hepatitis viruses. The policy adopted in Scotland was as set out in the 14th December 1984 UKHCDO Circular by Professor Bloom.<sup>41</sup>

**22.24** As far as cryoprecipitate was concerned:

Cryoprecipitate was a non heated product, prepared from individual donors, which could transmit HIV and hepatitis viruses. Once the lifetime patient exposure to cryoprecipitate reached approximately 100 donors (about 5 infusions in an adult) the risk of non-A non-B hepatitis approached 100%.

Until October 1985, donors were not tested for anti-HIV. After this date there was uncertainty about its efficacy to exclude all donations infectious for HIV. This was because there was uncertainty about the sensitivity of the anti-HIV test to detect all antibody positive donations. Furthermore there were potentially donors, recently infected with HIV, who were viraemic, but in whom the anti-HIV antibody had not yet arisen, and whose donation would therefore be infectious but would not be detected by the anti-HIV test. This is the so called 'window period' and can last up to about 6 months after primary infection with HIV. Later techniques were developed to detect HIV in the 'window period', in the absence of antibody, (NAT (nucleic acid testing)) and these are now in current use for screening donations).

During the period 1984–1987, if only a single, or very occasional, treatment with a blood product was required, it could be argued that cryoprecipitate was safer, with respect to non-A non-B hepatitis, than heat-treated NHS concentrate. The disadvantage of cryoprecipitate, however, was that it was not heat-treated and therefore could transmit HIV.<sup>42</sup>

**22.25** Thus, treatment policy in Edinburgh during the period under investigation for patients with Haemophilia A or von Willebrand's disease who were probably not infected with NANB Hepatitis was as follows:

- Children with severe or moderate haemophilia would be treated with cryoprecipitate or heat-treated Factor VIII.
- For those with mild haemophilia and von Willebrand's disease, the options were: to manage without the use of a blood product; to use DDAVP where possible; to use cryoprecipitate occasionally for treatment of Haemophilia A when only small amounts of treatment were necessary; or to use heat-treated Factor VIII.
- The heat-treated concentrate used would have been the PFC-issued NY, heat-treated at 68°C for 24 hours, apart from after August 1986, when a small supply of 8Y existed in Scotland and was available for patients not previously exposed to the virus who presented with a major bleed.<sup>43</sup>

<sup>41</sup> Ibid [PEN.017.1790] at 1792

<sup>42</sup> Ibid [PEN.017.1790] at 1793

<sup>43</sup> Summarised from Professor Ludlam's statement on the use of blood product concentrates between 1984 and 1987 [PEN.017.1790] at 1794–5

**22.26** For patients with Haemophilia B, the options were fresh frozen plasma or unheated NHS Factor IX, until October 1985, when product heated at 80°C for 72 hours became available in Scotland.<sup>44</sup>

**22.27** In oral evidence, Professor Ludlam agreed that the incidence of NANB Hepatitis from unheated concentrates was understood at that time to be very, very high.<sup>45</sup> Specific information regarding the incidence in haemophilia patients in Edinburgh in 1989, shortly after HCV tests were developed, was available to the Inquiry. This was in the form of a letter sent by Professor Ludlam et al to *The Lancet*. Sera from 61 patients with Haemophilia A or B or von Willebrand's disease had been tested for antibody to HCV. Of the 48 who had received non-heated concentrates (before 1985), 41 were seropositive by this early anti-HCV test. It was not clear at the time why all 48 were not seropositive. The negative cases may have been or included individuals who had cleared the virus and, over time, had become anti-HCV negative or, given that it was an early test, they may have been HCV positive at the time but not identified by the test. Of the remaining 13, seven had received only heat treated concentrates and all were seronegative. Six who had received only cryoprecipitate or red cells were also negative.<sup>46</sup>

**22.28** Professor Ludlam's awareness at that time of the severity of NANB Hepatitis was also explored. First, he was asked about the article entitled 'Progressive liver disease in haemophilia: an understated problem?' by Dr Hay et al in *The Lancet* of 29 June 1985.<sup>47</sup> The article was familiar to Professor Ludlam and he thought it would have been so at the time of its publication. He considered that the aspect which had not been previously appreciated up to that point was that the disease was progressive.<sup>48</sup>

**22.29** Next, Professor Ludlam was shown an article from *Blood*, published in August 1985, entitled 'A study of liver biopsies and liver disease among hemophiliacs'.<sup>49</sup> The study had involved 155 patients with haemophilia, some of whom had received a lifetime exposure to more than 100,000 units of concentrate. The incidence of cirrhosis found was 15%, with chronic active hepatitis affecting 7%. The article recognised the possibility of insidious progression to cirrhosis. Professor Ludlam remembered noticing it at the time.<sup>50</sup>

**22.30** A further letter on this topic (this time from Dr Schimpf) appeared in *The Lancet* of 8 February 1986, reporting results from the haemophilia centre in Heidelberg. The author agreed with Dr Hay and his colleagues that liver disease in haemophilia was an understated problem.<sup>51</sup> Professor Ludlam described Dr Schimpf as 'a very distinguished haemophilia treater'.<sup>52</sup> He was sure he would have seen the letter.<sup>53</sup>

**22.31** In the light of this material, Professor Ludlam offered his view that it was around that period that it 'became clear that it [liver disease in haemophilia] was potentially serious and potentially progressive'.<sup>54</sup>

*The London Hospital*

**22.32** Dr Colvin assisted the Inquiry by giving evidence both in relation to his own practice at the London Hospital, one of four centres in London, over the period examined, and also by endeavouring to put himself in the position of a haemophilia clinician in Scotland.

**22.33** In his evidence, Dr Colvin was asked about the role of cryoprecipitate at that time. Initially, he expressed considerable reservations about the therapeutic potential of cryoprecipitate during the period under examination. He was referred to a study, published in *Clinical and Laboratory Haematology* in 1987, in which he had reported on six patients, not previously exposed to concentrates, who were treated with cryoprecipitate between October 1982 and July 1984.<sup>55</sup> No patient had shown signs of NANB Hepatitis. The report suggested that, following the introduction of screening of donated blood for anti-HIV in October 1985, the use of cryoprecipitate in selected cases should be reconsidered. Notwithstanding these published views, Dr Colvin felt that by the time of publication, ‘the world had moved on, and I think by that time we had really given up using cryoprecipitate’.<sup>56</sup> In expressing these views, he highlighted the interval between the study and the date of publication of the article. He considered that the paper revealed the uncertainty of the period, and the range of options which were examined.

**22.34** On his second day of giving evidence on this topic, however, Dr Colvin slightly refined his position on the use of cryoprecipitate:

I suspect that by 1986, despite my publication in 1987, I would have thought twice about using cryoprecipitate. But I think it would not have been an unreasonable point to have made, [that the safety of cryoprecipitate had been improved by HIV screening of donors] and the fact that I allowed my paper to be published in 1987 implies that I thought even at that time it was a reasonable approach to the problem. But you would have to take every case on its merits. As I implied in my previous answer, one had to factor such a lot of different issues into the equation before you made a decision, and the decision you made wasn’t necessarily the right decision and it was perfectly possible for another physician to make a reasonable different decision.<sup>57</sup>

In other words, therefore, there was a period – a ‘brief window’<sup>58</sup> – after the introduction of donor screening for HIV when cryoprecipitate could have been a possible treatment for some patients if one were worried about the safety of the available concentrate.<sup>59</sup>

**22.35** On his first appearance on this topic, when asked how he would have treated patients had he been in Scotland during this period, Dr Colvin referred to the possibility of either postponing elective procedures to avoid the use of blood products or using desmopressin.<sup>60</sup> Where treatment was necessary:

<sup>55</sup> Colvin et al, ‘A prospective study of cryoprecipitate administration: absence of evidence of virus infection’, *Clinical and Laboratory Haematology*, 1987, 9:13–15. [LIT.001.0640]

<sup>56</sup> Dr Colvin – Day 55, pages 136–7.

<sup>57</sup> Dr Colvin – Day 74, page 106

<sup>58</sup> Ibid page 105

<sup>59</sup> Professor Howard Thomas was referred in evidence to an article he co-authored with haemophilia clinicians: Kernoff, PBA et al, ‘High Risk of non-A non-B hepatitis after a first exposure to volunteer or commercial clotting factor concentrates: effects of prophylactic immune serum globulin’, *British Journal of Haematology*, 1985; 60:469 [LIT.001.0800]. The article was submitted in 1984. In the conclusions, reference is made to patients with mild bleeding disorders now being ‘more appropriately treated’ with cryoprecipitate or desmopressin than with concentrates. See Professor Thomas – Day 52, pages 87–106. See also his further comments on cryoprecipitate at Day 52, page 156.

<sup>60</sup> Dr Colvin – Day 55, pages 148–9

[I]t was extremely difficult to know what to do. But I think that for very small usage in adults, where you were going to really have quite a small number of units and then not use any more, for instance for very mild haemophilia, where you couldn't use DDAVP, [cryoprecipitate] was an option. I think that for very small children, where tiny volumes of cryoprecipitate would achieve haemostasis, it was also an option but it was an option with diminishing benefits as the number of units went up.

Q. Yes. And I suppose the other consideration that struck me is that in this period, even with a child who has severe haemophilia, you could reason that a better product might be going to come along, so you are not talking about trying to assess how much cryoprecipitate this child will require for the next ten or 20 years. It might be for quite a short period?

A. That is exactly [what] my reasoning was in carrying on with cryoprecipitate until 8Y became available for the children.<sup>61</sup>

**22.36** Dr Colvin referred again to the many uncertainties prevailing during this period. It was really only possible to 'do what seemed a good idea at the time'.<sup>62</sup>

I still feel that any decision made to use 8Y or the Scottish equivalent at that point was based on a kind of informed intuition. I certainly would have liked to have said at the time that I was convinced that one product was better than another. I think we were all extremely relieved when it became apparent that 8Y and the Factor IX equivalent in due course actually were safe. It was a piece of – I was going to say good luck; it wasn't good luck exactly but I think we were all extremely relieved that in retrospect this was the case. But I think there is huge danger of using the retrospectoscope to say that one should have taken the particular view because it later turned out that that was the answer.<sup>63</sup>

**22.37** Had he been in Scotland, would he have tried, as Professor Ludlam did, to obtain a supply of the English product?<sup>64</sup> Dr Colvin thought it more likely that his course of action would have been to wait and see in relation to developments in England.<sup>65</sup>

**22.38** On the second occasion on which he gave evidence on this topic, Dr Colvin was again asked about what he did during the relevant period and what he would have done had he been practising in Scotland. He replied:

I have suggested that I would have used heat-treated commercial Factor VIII concentrate where essential, especially for more significant bleeding episodes or major surgery, where the use of substantial quantities of concentrate was anticipated. So what we had really was a policy of trying to look after those who had been least treated and trying to look after, really, children. So until the spring/summer of 1985, I was still trying to use cryoprecipitate for the children but I then changed over to 8Y really as soon as it became available, and I think probably around the time of this letter [to haemophilia directors dated 24 July

---

<sup>61</sup> Ibid pages 151–2

<sup>62</sup> Ibid page 156

<sup>63</sup> Ibid page 157

<sup>64</sup> Professor Ludlam's request for 8Y from England is narrated below at paragraph 22.54

<sup>65</sup> Dr Colvin – Day 55, page 158

1985<sup>66</sup>]. As far as adults were concerned, particularly, I am afraid, people who had been given a lot of treatment in the past, or who were due to have major surgery which would require a lot of concentrate to be given, then it was very often the case that we had to consider using commercial heat-treated concentrate because, as I think was made clear around that time, the provision of 8Y was only sufficient for a proportion of the patients under our care.<sup>67</sup>

**22.39** For any individual adult patient, who had not previously received concentrates but required treatment, there would be questions as to how much was likely to be used. Dr Colvin would have wanted to avoid using too much 8Y for any one individual. But if only a small amount was going to be used, then it would have been 8Y: 'that was what was available to us and we thought that was the best concentrate to use at the time'.<sup>68</sup> In addition, such a patient was actually a valuable resource as far as new products were concerned, so Dr Colvin would have wanted to try to enter him in a trial if possible.<sup>69</sup>

**22.40** In the last part of his testimony, Dr Colvin reminded the Inquiry that:

[I]t wasn't easy to know what the right answer was, and the responsible physicians acting within the spectrum of appropriateness sometimes came to different conclusions.<sup>70</sup>

## 8Y

### *Emerging information about safety*

**22.41** As previously noted, there appears to have been no use of the English heat-treated Factor VIII product, 8Y, in Glasgow.<sup>71</sup> But it was used in Edinburgh. It is therefore necessary to consider the background to the use of English product to treat patients in Scotland.

**22.42** 8Y was treated at 80°C for 72 hours.<sup>72</sup> It was issued routinely for the treatment of patients with haemophilia in England with effect from September 1985. The Inquiry was interested to ascertain when clinicians in Scotland became aware of this product, and what view they took of it.

**22.43** In his statement, Professor Ludlam pointed out that:

The viral safety, with respect to transmission of non-A non-B hepatitis, of the BPL product, treated at 80 degrees/72 hours, introduced in England in September 1985 was unknown at that time. It was not until mid 1986 that evidence started to be reported to suggest that it might be a 'hepatitis reduced' concentrate.<sup>73</sup>

**22.44** In evidence, he reminded the Inquiry that, although 8Y was of particular benefit to patients who had not previously been treated with concentrates, in that it prevented their being infected with NANB Hepatitis, the priority in England in 1985 was to protect all haemophilia patients from HIV.<sup>74</sup>

<sup>70</sup> Ibid page 103

<sup>71</sup> See paragraph 22.21 above

<sup>72</sup> The technical background to the achievement of this heating protocol in England is dealt with in Chapter 24, *Viral Inactivation of Blood Products for Haemophilia Therapy 1985–1987*

<sup>73</sup> Professor Ludlam's statement on the use of blood product concentrates between 1984 and 1987 [PEN.017.1790] at 1791

<sup>74</sup> Professor Ludlam – Day 54, page 99

**22.45** In relation to the view which clinicians had at that time of the safety of 8Y, Professor Ludlam recalled that there was no certainty at all that dry heat treatment to 80°C would be effective in respect of removing NANB Hepatitis transmission risk, and there was a lot of international scepticism about dry heat treatment at any temperature being effective.<sup>75</sup>

**22.46** The contemporaneous material was reviewed with Professor Ludlam in evidence. At PFC on 17 March 1986, a meeting took place between fractionators based in Scotland and England. In paragraph 5 of the minutes of the meeting relating to viral inactivation, it is recorded that:

Dr Smith outlined clinical trial results of the 8Y F VIII product so far. While results cannot be considered conclusive at this stage, he indicated that no cases of virus infection have occurred (attributable to 8Y material) after 12 months' experience of 8Y in virgin haemophiliacs.<sup>76</sup>

Professor Ludlam pointed out certain flaws in this information, but was willing to accept that these might be questions of the weight this information should bear.<sup>77</sup>

**22.47** Turning to events in England, Professor Ludlam was shown the minutes of a meeting of the Central Blood Laboratories Authority (CBLA), Central Committee for Research and Development in Blood Transfusion on 9 July 1985.<sup>78</sup> The minutes referred to a trial, then ongoing, in which patients thought to be susceptible to NANB Hepatitis (because they had either never previously had concentrate or had not had it for a long time) were given 8Y. Several of them had already passed the point at which the first evidence of NANB Hepatitis transmission would have been expected. That information is also contained in an information sheet dated 24 July 1985, issued by BPL and distributed to all haemophilia directors and regional transfusion directors in England and Wales.<sup>79</sup> The sheet explains that the product has been heated at 80°C for 72 hours to reduce the risk of viral infection, and that 'further assurance is sought over freedom from risk of viral transmission'.

**22.48** In the light of this material, Professor Ludlam was asked if, in 1985, he was hearing 'news from England'. Although he would not have received the information sheet, he told the Inquiry that he was aware the studies were going on, and pointed out the difficulty in recruiting patients for such an exercise. Whilst he found it difficult to recall conversations or other sources of information, he put the date of his knowledge – a 'general feeling' – about 8Y at 1986.<sup>80</sup> He also reiterated that there was 'a lot of scepticism' about how effective dry heat treatments would be.<sup>81</sup>

**22.49** He was later asked if Dr McClelland had reported to him 'encouraging' signs regarding the English product that were mentioned at a subsequent meeting of the CBLA Central Committee for Research and Development in Blood Transfusion on 19 December 1985.<sup>82</sup> Professor Ludlam thought not.

<sup>75</sup> Ibid page 100

<sup>76</sup> Note of a meeting held at PFC on March 17 1986 [SNB.007.5664] at 5666. Dr Smith gave extensive evidence about the technological progress in developing 8Y and testing its effectiveness which is discussed elsewhere.

<sup>80</sup> Professor Ludlam – Day 54, pages 106–107

<sup>81</sup> Ibid page 108

<sup>82</sup> Professor Ludlam – Day 55, pages 96–98

**22.50** It was also suggested to Professor Ludlam that there was a much more local source of information about 8Y. In January 1986, Dr Perry wrote a report for the regular joint meeting of SNBTS directors and the haemophilia directors.<sup>83</sup> In it, he recorded that the BPL was now issuing their product heated at 80°C for 72 hours and that ‘preliminary clinical data’ indicated that this material was ‘non-infective with respect to HTLV III, NANB and Hepatitis B’.<sup>84</sup> The meeting was held on 5 March 1986; in fact Professor Ludlam sent apologies and, in evidence, he was not clear about whether or not he would have received the background papers.<sup>85</sup>

**22.51** At a meeting of Haemophilia Reference Centre Directors on 22 September 1986, Dr Rizza presented the directors with a paper on the study into the effectiveness of the heat treatment of 8Y (and its equivalent for Haemophilia B, 9A).<sup>86</sup> The analysis was restricted to results in those patients who had no previous exposure to concentrates, although some had received cryoprecipitate. Fortnightly measurements had taken place to detect raised liver enzymes and the trial had also involved exposure to multiple batches, to create greater exposure in the patients. None of the patients had recorded an ALT or AST measurement above 2.5 times the upper limit of normal. Dr Smith acknowledged in his report that the data were inconclusive due to some gaps in follow-up, but might nonetheless further encourage haemophilia directors to use 8Y and 9A in previously untreated patients. A statistician had calculated that the number of negative cases found could still be consistent with an infectivity rate of up to 14%; that was plainly better than for unheated concentrates. This pilot study was to be followed by a more formal prospective controlled trial with a stricter protocol.<sup>87</sup>

**22.52** As with the information presented at the meeting at PFC,<sup>88</sup> Professor Ludlam pointed out weaknesses in the data. But he agreed that the information was ‘reassuring’.<sup>89</sup>

**22.53** This report was also reviewed with Dr Colvin. He pointed out that the numbers of patients were very small. Although no infection was found in the patients treated, infection might have been apparent had a larger number of patients been involved. He also pointed out that some of those who were tested could previously have had NANB Hepatitis and cleared the virus, therefore if they had been infected by 8Y, that infection would not have been evident.<sup>90</sup> He was not, however, critical of the use of patients who had had some previous exposure to cryoprecipitate: ‘the use of patients who were not truly untreated was a risk worth taking to get the data that one needed to be reasonably confident that a particular product was safe’.<sup>91</sup> There had been false dawns before – heat-treated products had previously been demonstrated to continue to transmit both NANB Hepatitis and HIV, so all those involved were understandably cautious about how safe

<sup>83</sup> PFC Report for SHS Haemophilia/SNBTS Directors Meeting (March 1986) [SNB.001.5469]

<sup>84</sup> Ibid [SNB.001.5469] at 5472

<sup>85</sup> Professor Ludlam – Day 54, page 110

<sup>86</sup> The Inquiry has a copy of a paper *Surveillance of previously untreated patients for possible virus transmission by BPL Factor VIII and Factor IX concentrates, 8Y and 9A: Interim Report* [SNF.001.1123], but the paper refers to information being summarised by Dr Jim Smith on 30 September 1986 – some revision of, or addition to, the paper must therefore have taken place between 22 and 30 September. The information quoted in paragraph 22.51 is drawn from the paper.

<sup>87</sup> A fuller report, giving results in relation to 32 patients, was published as ‘Effect of Dry-Heating of Coagulation Factor Concentrates at 80 c for 72 Hours on Transmission of Non-A, Non-B Hepatitis’, *The Lancet*, October 8 1988; 814–816 [LIT.001.0330]. This was discussed by Dr Colvin in his report for this topic, [PEN.017.1674] and in evidence at Day 55, Page 145. Even this study did not fulfil the protocol for such research laid down by the International Society on Thrombosis and Haemostasis (ISTH) – Dr Colvin – Day 74, page 93.

<sup>88</sup> See paragraph 22.46 above.

<sup>89</sup> Professor Ludlam – Day 54, page 116

<sup>90</sup> Dr Colvin – Day 55, page 143

<sup>91</sup> Ibid page 144

any new product might actually prove to be.<sup>92</sup> Even as late as 1988, in an article dealing with a number of different studies which had been carried out into treated products, Mannucci and Colombo felt able to say only that Factor VIII concentrates treated at 80°C were ‘presumed innocent’.<sup>93</sup>

### *Supply of 8Y to Edinburgh*

**22.54** Despite reservations, Professor Ludlam appears to have had about the information emerging in 1985 and 1986 regarding 8Y, he nevertheless took steps to obtain some for patients. On 27 June 1986, Dr Boulton, deputy director of the Edinburgh and South East Scotland Regional Blood Transfusion Service, wrote to Dr Cash about the development of heat-treated products in Scotland. In his letter, he related a conversation he had had with Professor Ludlam about trials of more severely heated product prepared in Scotland. 8Y had been mentioned:

Apparently a few weeks ago he was asking Brian McClelland if VIIIY could be made available in the event of a “virgin” haemophiliac being presented.<sup>94</sup>

**22.55** Professor Ludlam thought that the background to this must have been that someone had passed on the latest information about 8Y. It probably then came up in conversation with Dr McClelland that 8Y was a better product than the Scottish heat-treated product insofar as the prevention of NANB Hepatitis was concerned.<sup>95</sup> He was asked why, given the limitations on the information then available about 8Y, he was still interested in obtaining some. For him it was an issue of comparative risk. It was highly likely that all SNBTS concentrate then available, heated at the time at 68°C for 24 hours, would transmit hepatitis. The evidence from the 8Y studies was that it appeared to be less likely to transmit non-A non-B Hepatitis. It was a matter of degree. 8Y would be an improvement on what was currently available in Scotland. It might not be hepatitis-free but it might be less infective.

**22.56** Another letter from Dr Boulton dated 27 June 1986 was also examined in evidence with Professor Ludlam. This time, Dr Boulton was writing to Dr Perry at PFC.<sup>96</sup> His letter included the following passage:

A young haemophiliac who previously had minimal therapy with factor VIII received an infusion of the current heat-treated product a month ago. He now shows signs of liver enzyme rises indicating non-A non-B hepatitis. Christopher [Ludlam] is a bit ruthless with his own staff about this because he feels that this patient should have received VIIIY or an equivalent product. However, the patient is apparently quite well clinically.<sup>97</sup>

**22.57** The Inquiry was interested to explore with Professor Ludlam whether the episode referred to in Dr Boulton’s letter had been the impetus for his attempt to obtain a supply of 8Y.

<sup>92</sup> Ibid pages 144–45; Dr Colvin’s report on the use of blood product concentrates between 1984 and 1987 [PEN.017.1674]

<sup>95</sup> Professor Ludlam – Day 54, page 119

<sup>96</sup> Dr Boulton’s letter of 17 June 1986 to Dr Perry [SNB.007.5871]

<sup>97</sup> It appears that the patient was transfused in May 1986.

**22.58** The word used by Dr Boulton to describe Professor Ludlam’s feelings at the time (‘ruthful’) was unusual. Professor Ludlam described himself as having been sad that his team had not had 8Y to give to the patient at the time. He did not disagree with Dr Boulton’s articulation of these sentiments.<sup>98</sup> It was put to Professor Ludlam that this incident had the effect of sharpening his focus on obtaining some 8Y. He answered:

To be honest, I’m not certain which way round it occurred. I think it was in my discussions with the blood transfusion colleagues after it had happened, that the real potential, possible extra safety of 8Y was being highlighted in my mind.<sup>99</sup>

**22.59** He emphasised to the Inquiry the preciousness of 8Y in England; for the first time, clinicians there had a heat-treated NHS product, after having been desperate for one in the first part of 1985. Every bottle was valued and he was not sure that he would be able to have any, should he make such a request.<sup>100</sup> He concluded:

So I’m sorry, I can’t remember exactly how the sequence of thoughts went. But certainly this sad episode of a patient susceptible to non-A non-B [who] had acquired non-A non-B ... highlighted the issue.<sup>101</sup>

**22.60** He was then asked whether, if he personally had been looking after the patient concerned and had had a supply of 8Y, he would have used it. Professor Ludlam thought that, in these circumstances, he would have been ‘very tempted’ to use it.<sup>102</sup>

**22.61** The evidence concerning the dissemination of guidance to more junior staff about the treatment of patients and about the circumstances in which blood products should be used is discussed more fully in paragraphs 22.71 to 22.86 below.

**22.62** As far as the obtaining of 8Y in 1986 is concerned, the Inquiry followed the trail of correspondence culminating in the sending to Edinburgh of a small stock of 8Y in August 1986. Dr Perry replied to Dr Boulton on 2 July 1986. The PFC was ‘poised to introduce yet another FVIII product which will be heat treated at 80°/72hours and should therefore be comparable to 8Y’. As soon as this product was available, virgin patients (previously untreated patients, sometimes referred to as ‘PUPs’) would be able to gain access to it.<sup>103</sup> On 4 July, Dr Boulton wrote to Dr Perry,<sup>104</sup> asking him to confirm that Dr Boulton’s notes of their telephone conversation the day before<sup>105</sup> were accurate. By letter dated 7 July, Dr Perry confirmed they were ‘about right’. He added:

While there will be no PFC product virucidally comparable to 8Y until September ‘86, after that time it would be my intention to supply the Phase III product [the 80°/72 hours product, virucidally equivalent to 8Y] to “virgins” since we hope to demonstrate by that time that it is virucidally equivalent thus removing the need to go South. However, in the immediate future (July–September ‘86), we could probably get supplies of 8Y for special cases. It would of course be preferable if these were obtained and supplied through PFC.<sup>106</sup>

<sup>98</sup> Professor Ludlam – Day 54, page 121

<sup>105</sup> Dr Boulton’s notes [SNB.007.5911] The notes are shown in typed form in the Preliminary Report at paragraph 11.315.

<sup>106</sup> Dr Perry’s letter of 7 July 1986 to Dr Boulton [SNB.007.5913]

**22.63** On 7 July, Dr Boulton wrote to Dr Perry again, apologising for ‘pestering’ him. Dr Ludlam had written to Dr McClelland asking if it would be possible to obtain some of the BPL products for use ‘if a previously untreated haemophilic presented for replacement therapy’. Dr Ludlam was asking for 500 vials. Dr Boulton felt this was a large quantity. He wanted to know if it might be possible for Dr Perry to obtain perhaps 50 vials. This would be enough to cover an initial injection and, if necessary, more could be sought urgently from Oxford.<sup>107</sup> Accordingly, on 10 July, Dr Perry wrote to Mr Norman Pettet at the BPL, relaying the request for 50 vials.<sup>108</sup>

**22.64** On 24 July, Mr Pettet replied. He said that he had tried to telephone Dr Perry the previous week. With Dr Lane’s agreement, he had spoken to Dr Jim Smith, who had ‘a novel proposal’ for Dr Perry: ‘perhaps Scotland would like to participate in our trial of Factor VIII Y!’. Dr Perry and the haemophilia directors involved would have to agree, and the patients would have to meet the criteria. But in case there were some patients who did not strictly meet the criteria, now or in future, Mr Pettet had put aside some 8Y for immediate despatch to PFC (or any other destination) if required. He could arrange for the product to be sent to PFC at that point, unless arrangements for cover had already been made with Dr Smith.<sup>109</sup> But on the same day, Dr Perry wrote to Dr Boulton. He had now confirmed that BPL were happy to supply 50 vials to PFC ‘on the understanding that, in the event that the material is used in suitable virgin patients, appropriate serial samples would be taken to contribute to their overall infectivity study’. Dr Perry thought this arrangement was reasonable; he would pass the product to Dr Boulton as soon as possible and he would be grateful if Dr Boulton could inform Dr Ludlam of the arrangement.<sup>110</sup> Also on 24 July, Dr Perry wrote to Dr Smith at BPL, confirming the arrangement made by telephone and asking for a supply of 50 vials of 8Y as a contingency. This material would be issued on condition that BPL’s clinical trial protocol was observed.<sup>111</sup> On 28 July, Dr Perry confirmed matters to Mr Pettet.<sup>112</sup>

**22.65** On 1 August, Dr Smith wrote to Dr Perry, sending 50 vials of 8Y and some copies of the clinical protocol.<sup>113</sup> He referred in his letter to the use of the 8Y to protect ‘Category 1 patients’ – Dr Smith explained that these will have been previously untreated patients, though he was not able to remember the precise definition of such patients.<sup>114</sup> On 5 August Dr Perry wrote to Dr Boulton to inform him that the supply of 8Y had arrived and that 20 vials had been sent to the transfusion centre at the Royal Infirmary in Edinburgh.<sup>115</sup> On 7 August, Dr Perry wrote to Dr Boulton again, advising him that two batches of Factor VIII heated at 80°C for 72 hours had been manufactured and that PFC were on target to begin trials of this product at the end of August or beginning of September.<sup>116</sup>

**22.66** Professor Ludlam gave evidence about his actual use of the 8Y thus obtained. This was a precious commodity: Professor Ludlam thought he would have told his own staff about the product, but they would not have been free to use it – they would have been expected to seek permission from him.<sup>117</sup>

<sup>116</sup> Dr Perry’s letter of 7 August 1986 to Dr Boulton [SNB.007.6048]

<sup>117</sup> Professor Ludlam – Day 55, page 65

**22.67** Of the 50 vials, Professor Ludlam used 20 vials for a patient with an allergic reaction to PFC NY concentrate. He subsequently obtained some more 8Y from Newcastle. He could not remember if this was because the other 30 vials had been used up.<sup>118</sup> Professor Ludlam referred to himself as having breached the understanding on which the 8Y had been given, in that he used it not for a previously untreated patient but for a patient with an allergy to PFC product.<sup>119</sup> He also acknowledged that being allowed to have any at all was outwith the normal arrangements for the supply of products by the BPL:

[E]ach English region had an allocation of 8Y, depending on how much plasma it supplied to BPL. As Scotland didn't supply any plasma to BPL, it had, in a sense, no right of access to 8Y. So it was a concession that had to come out of somebody else's supply, one of the English health authority's allocation.<sup>120</sup>

**22.68** It can be seen from the circular letter dated 24 July 1985 that the supply of 8Y to centres in England was tightly controlled, in view of the scarcity of the product. The circular provides:

It is recognised that, until the new production unit at Elstree is completed, output of 8Y will meet about one third of current demand for concentrate and for this reason, attempts have been made to define those patients likely to benefit most from the security inherent in 8Y.

Therefore, Haemophilia Centre Directors are being asked to compile lists of their patients considered 'at risk' and most Centres have complied. It is the considered view at BPL that, where possible, liaison between the Haemophilia Services and the BTS should aim at directing Factor 8Y to these patients, using the existing framework of distribution and supply.<sup>121</sup>

**22.69** On his second day of giving evidence on this topic, Professor Ludlam was asked why no request for a supply of 8Y for previously untreated patients in Scotland was made before the summer of 1986. He suggested that such a question needed to be put to someone from the Blood Transfusion Service. As indicated above, he had been pressing Dr McClelland on supplies of 8Y, and Dr Perry thought that the PFC would have been the appropriate intermediary. In responding to subsequent questioning, he observed that, rather than his request being obviously the right thing to have done at the time, it might have transpired that he had 'rather jumped the gun' as the trial was still ongoing and the product might have turned out not to be materially better.<sup>122</sup>

### *Telling other clinicians in Scotland*

**22.70** Professor Ludlam was also asked whether this stock of 8Y was for the whole of Scotland.

Q. Just one last matter, professor. When this supply of 8Y was obtained in the summer of 1986, was it for Edinburgh patients or was it for everybody in Scotland?

---

<sup>118</sup> Ibid pages 141–2 and pages 119–120

<sup>119</sup> Ibid page 120

<sup>120</sup> Ibid page 121

<sup>121</sup> Information Sheet, *Dried Factor VIII Concentrate: High-Purity, Heat Treated*, issued to English and Welsh Haemophilia Directors and Regional Transfusion Directors by Blood Products Laboratory, 24 July 1985 [DHF.003.0476]

<sup>122</sup> Professor Ludlam – Day 55, page 109

A. Well, as I think is clear, I requested it and it was held primarily at the protein fractionation centre and therefore it was available for anyone who wished to apply to use it.

Q. Yes. And Dr Perry didn't send you all 50 vials?

A. He sent me 20, I think.

Q. But as matters turned out, I think you used the whole 50 vials. Did you ever mention to any of your colleagues in Scotland that that stock existed?

A. I assume that would be a responsibility for Dr Perry. He had a new product available for patients.

Q. Right. Is that a "no". Do you have any memory of ever saying in a conversation, "Oh, there is a stock of 8Y at PFC?"

A. I'm sorry, I can't remember.<sup>123</sup>

**22.71** In light of this evidence, Dr Perry was also asked about the securing of this stock of 8Y, and whether there was an arrangement that this 8Y was available on a more general basis for patients in Scotland? He replied that colleagues at the BPL:

[W]ere prepared and able to supply small quantities of product for specific clinical situations, and the specific clinical situation was a previously untreated patient, and their positive response to our request demonstrated the principle that that was viable. I think if that had been then extended to an arrangement where BPL were being asked to supply product for all sorts of other reasons, an 8Y product, then I think they would have resisted that, for the reasons that I have described. So my clear understanding at the time was that this small supply of product was for very specific requirements.<sup>124</sup>

**22.72** Dr Perry was asked whose responsibility it was to inform clinicians in other parts of Scotland that this small supply of 8Y was available. He replied:

A. There were basically two options, and, of course, with hindsight, the best outcome would have been that either myself or Dr Ludlam, as chairman of the Scottish haemophilia centres directors study group – either of us could have more widely notified the other four haemophilia centre directors that this product was available and, to the best of my knowledge, that didn't occur.

Q. Can you give us any explanation or indication as to why that may not have occurred?

A. I have attempted to give you the explanation why I didn't take that particular position, because I didn't think it was a responsibility. Again, against this backdrop of being quite clear to make sure that, as a manufacturer, we were not exceeding our brief, I thought it was not the responsibility of SNBTS or indeed the PFC director, the manufacturer, to make wider notification of this. This was a specific facilitating arrangement that we carried out on behalf of Professor Ludlam.<sup>125</sup>

---

<sup>123</sup> Ibid pages 63–64

<sup>124</sup> Dr Perry – Day 74, page 51

<sup>125</sup> Ibid pages 53–54

**22.73** Dr Perry was asked if he could have sent a circular advising of the stock of 8Y. He agreed that that could have been done.

I think, with hindsight, I would certainly agree that that would have been an appropriate thing to do but I would still suggest that a more appropriate thing to do would have been for the haemophilia centre directors themselves to have – in the knowledge that this was available – we had established the principle with Professor Ludlam – then there was a possibility that they too could have communicated amongst themselves.<sup>126</sup>

He continued:

But I think I'm trying not to suggest that we could not have had a role to play here, and I think with hindsight I would agree: if I had my time again, I think I could have quite simply ... written to other haemophilia centre directors – actually, it would have been to regional transfusion directors as well, who were responsible for supply of the product – and made them available [aware]. It's quite possible – I have absolutely no evidence that this took place, but through various informal channels and communications I would have mentioned that this actually happened but I have no evidence for that.<sup>127</sup>

**22.74** In view of Dr Perry's reference to the Scottish Haemophilia Centres Directors' Study Group, the Inquiry has examined whether the directors were meeting as a group at this time. According to Professor Ludlam, the Scottish directors met as a group from about 1985.<sup>128</sup> In any event, they will have encountered each other regularly at meetings, and knew each other's identity and contact details. Information about the obtaining of a small supply of 8Y could have been disseminated among them by Professor Ludlam.

**22.75** There also arises the question of how hospitals in Scotland which did not have haemophilia centres but which might find themselves dealing with a person with haemophilia in an emergency would know that there was a supply of safer product for such patients in Edinburgh. This is further referred to below at paragraph 22.98 in the context of 'horizontal dissemination' of guidance.

### **Dissemination of guidance**

**22.76** The Inquiry was contacted by two people with haemophilia who contracted Hepatitis C from blood products during the period 1985–87. One of these individuals was treated in Edinburgh, not by Professor Ludlam personally but by a junior clinician, at night. The other person was treated in a remote part of Scotland. The Inquiry explored in evidence the issues of how guidance was given by senior clinicians to more junior staff ('vertical dissemination') and, given that people with previously undiagnosed haemophilia might present at any hospital at any time, how guidance was distributed around Scotland ('horizontal dissemination').

---

<sup>126</sup> Ibid page 56

<sup>127</sup> Ibid page 57

<sup>128</sup> Professor Ludlam – Day 18, page 7. Compare, however, other evidence set out at paragraph 22.87.

### *Vertical dissemination*

**22.77** Professor Ludlam was asked what steps he, as a haemophilia centre director, had taken to ensure distribution of guidance on treatment during the relevant period to members of staff who might be encountering patients with haemophilia. In particular, he was asked about the guidance document prepared by Professor Bloom after the meeting on 10 December 1984.<sup>129</sup>

**22.78** In response, Professor Ludlam indicated that he thought that what was in the guidance document represented practice in the Edinburgh centre at the time. The team was small: Professor Ludlam, a lecturer, a registrar and a haemophilia sister, and policies were ‘generally accepted and well-known within the team’. He could not remember whether there were written policies, locally produced, at that time.<sup>130</sup>

**22.79** Professor Ludlam confirmed that, during the period under investigation, the patients whose treatment raised the most difficult issues were those individuals with little or no previous exposure to blood products. He thought it would be ‘quite clear’ that such patients should be discussed at a senior level. At one extreme, if a baby without previous exposure came in with a life-threatening bleed, a major intracranial bleed, then his judgement would have been that that child required concentrate, because of speed of administration and known level of Factor VIII in the therapy.<sup>131</sup> He would almost certainly have been contacted.<sup>132</sup> As far as new staff were concerned, Professor Ludlam pointed to the continuity offered by the haemophilia sister, and the lecturer, whose post was a more permanent one.<sup>133</sup>

**22.80** Professor Ludlam also told the Inquiry about weekly meetings:

We had weekly educational meetings, at which we would discuss our internal arrangements, our internal policies, we would have outside speakers. I seem to recall a speaker from the blood transfusion coming to talk about developments in clotting factor concentrates.<sup>134</sup>

These meetings took place at 8.30 am on Fridays.

**22.81** The Inquiry was interested to probe further how medical staff would know that particular patients – the 1% who were not regular patients at the Centre – posed difficult questions as far as treatment of bleeding was concerned. Professor Ludlam’s answer to this was that such individuals would obviously stand out. They would not have case notes. If that was because they were visiting Edinburgh they might have haemophilia cards, or they might be able to explain themselves what their normal treatment was.<sup>135</sup> Junior staff were always free to come straight to Professor Ludlam if they needed advice about a patient.<sup>136</sup> As far as those staff who might think they did not require advice were concerned, Professor Ludlam answered that he very quickly got an impression of the level of competence and understanding of a new member of staff. If over-confidence was a problem, he would speak to them. He always said to new staff to contact him if they had

a query. He endeavoured to give staff as much responsibility as he could and as much as they felt comfortable with, whilst also equipping them with an understanding of the sort of areas and topics that he liked to be informed about.

**22.82** Professor Ludlam's evidence on the matter of dissemination within the department ended with the following exchange:

Q. Professor Ludlam, because this is an Inquiry, I think I have to probe just a little bit further and put to you that the sort of scenario we have been discussing – that is the patient with mild haemophilia who needs treatment, who has had no or minimal previous exposure to concentrates, needing treatment, where there is a continuing risk of hepatitis, which is a very significant adverse consequence and the treatment decision is a very difficult dilemma – that whole package is something that called for specification, so a written document or an advance instruction from you communicated to all staff. Looking back, even just in retrospect, what's your response to that?

A. Well, it could give rise to the wrong therapy. Let me caricature. A patient with mild haemophilia is involved in a road traffic accident, comes into hospital unconscious, may have an intracranial bleed. The recipe, the guidance says give DDAVP for mild haemophilia. That would be totally inappropriate for many reasons I could go into, if you wanted to.

Q. I was wondering perhaps about a simpler response. What if the guidance said in block capitals "phone me"? Would that not help?

A. That is, in a sense, what the guidance was. Here is an unusual situation.

Q. But you didn't see the need for making that kind of provision in advance, as it were, for putting down in writing, so there wasn't debate, what you expected the response to be?

A. I expected people to get in touch with me if it was not clear how they should proceed with the medical care of patients. That applied not just to mild haemophilia. I looked after patients with leukaemia and lymphoma and a whole range of conditions, and if one of my staff had some doubt about how to proceed, then they asked me.<sup>137</sup>

**22.83** It was not clear that this explanation dealt with the full range of possibilities giving rise to a need for the intervention of a more senior colleague. More junior staff might not be aware that the situation confronting them raised a problematic issue. They might think, wrongly, that it was clear how the patient should be treated. However, it is highly improbable that any form of general guidance could exclude the possibility of incorrect clinical judgement.

**22.84** The question of what would happen if such a patient presented in the casualty department of the hospital was also covered with Professor Ludlam. He explained that if haemophilia was suspected, a clotting screen would be performed. If the results revealed mild haemophilia, then staff from the haematology department would go to see the patient themselves. That situation was very unusual.<sup>138</sup> Of course, if the patient had been investigated before, then the patient himself might be able to inform medical staff

---

<sup>137</sup> Ibid pages 58–60

<sup>138</sup> Ibid page 69

about any clotting problems. But with such investigations, wider questions might arise in borderline cases about whether or not a particular individual should be ‘labelled’ as having a clotting disorder, because of the implications such a diagnosis might have for other areas of his life, such as life insurance.<sup>139</sup>

**22.85** Professor Ludlam was asked to consider what would have happened during the relevant period if a patient who was bleeding arrived in casualty and also informed staff of some sort of history of bleeding easily. His answer was that a clotting screen would have been performed – the threshold for such an investigation was very low.<sup>140</sup> As far as the mechanics of requesting and arranging a clotting test were concerned, Professor Ludlam explained the interaction between casualty and the haematology departments as follows:

The system was that clotting tests came – we get a lot of requests for clotting tests from Accident & Emergency and if one turned up with an unexpected abnormality, as might occur in haemophilia, then that result was reported back to the person who requested it, and our duty registrar was informed and our duty registrar would then use his judgement as to whether or not to follow it up, and certainly if there was a question of a screening test potentially identifying a patient with haemophilia, then he would make sure the Factor VIII and Factor IX levels to start with were measured, and he would go and liaise with the doctor in the Accident & Emergency department.<sup>141</sup>

**22.86** Insofar as the decision about administering any blood products was concerned, Professor Ludlam would expect to have heard himself if a new patient with haemophilia was in casualty – although plainly circumstances might dictate otherwise if, for example, he was unavailable.<sup>142</sup> At first, Professor Ludlam thought that there was no written guidance issued to the casualty department by his department during the period being examined but, on reflection, he recalled that every two or three years, the haematology department met with the casualty department and updated a guidance sheet as to how staff in casualty should respond to a person who presented with haemophilia, or potential haemophilia.<sup>143</sup>

### *Horizontal dissemination*

**22.87** The Haemophilia Centre in Edinburgh was the reference centre for the centres in the east of Scotland, namely Dundee, Aberdeen and Inverness.<sup>144</sup> As reference centres, Edinburgh and Glasgow were part of ‘a UK arrangement for overseeing haemophilia treatment’.<sup>145</sup> In view of this, Professor Ludlam was asked what steps he had taken during this period to give guidance to those treating patients with haemophilia in those other centres. In response, he explained that, prior to the setting up of the Factor VIII working party in 1988:

[T]he centres were much more independent, standalone centres and there was not a great deal of interplay between them. Occasionally I would get a phone call about a difficult patient or something that was causing a difficulty or a problem, but there weren’t regular meetings like there are now, where we meet every two or three months.

<sup>139</sup> Ibid page 71

<sup>140</sup> Ibid pages 73–74

<sup>141</sup> Ibid Page 75. See also pages 78 and 79, for evidence to similar effect.

<sup>142</sup> Ibid page 76. See also pages 82–85.

<sup>143</sup> Ibid page 86.

<sup>144</sup> Professor Ludlam – Day 18, page 3

<sup>145</sup> Ibid page 62

Q. Right. You did use the word “overseeing” but it seems, from what you are now saying, as though, at least in the mid 1980s, it was more of a reactive role. So if somebody phoned you up for advice, you would be happy to provide it?

A. Yes, I think it evolved from being very separate, individual centres until the mid-1980s and, as a result of the development of all these new products and the need to test them, for one reason, brought us together to collaborate more.<sup>146</sup>

**22.88** The guidance document, prepared by Professor Bloom in December 1984, would have been sent to the other east of Scotland centres by the UKHCDO, from Oxford.<sup>147</sup>

**22.89** The Inquiry was interested in how physicians in other hospitals who might have to treat a patient presenting with haemophilia for the first time would have been aware of the most recent guidance. Professor Ludlam suggested that such clinicians would either use their best judgement, or telephone a haemophilia centre known to them.<sup>148</sup>

**22.90** There did not seem to be any system for sending guidance from the UKHCDO to hospitals around the country which were not haemophilia centres but which might suddenly have to deal with a patient who had haemophilia and who was in the midst of a bleed. Professor Ludlam suggested that, had a small child presented to a hospital in the Highlands with a bleed thought to be haemophilia, transfer to Inverness or Glasgow would be ‘the sort of usual [response]’.<sup>149</sup> He thought that, at the time which was being discussed, it would have been possible to get a small child to Inverness or Glasgow within 12 hours. He agreed that physicians in remote locations might not be aware of the most recent guidance on haemophilia, particularly with the centralisation of care which was already happening in the 1980s.<sup>150</sup>

**22.91** It was also put to Professor Ludlam that no-one in Scotland appears to have had the responsibility to change the 1984 guidance as different options became available or as the relative merits of the different products changed. Professor Ludlam thought this was ‘fair comment’, although he also pointed out that this was ‘a very, very confusing period’.<sup>151</sup> As far as general guidance for hospitals all over Scotland was concerned, Professor Ludlam was asked who would have been responsible for providing such advice:

Q. [W]e are thinking about this difficult period and if it were to be thought that it would have been a good idea for somebody to try to make sure that all hospitals in Scotland had some assistance with the current thinking on how to deal with patients with haemophilia presenting for the first time, say, or patients with mild haemophilia who hadn’t had previous exposure to concentrates, the patients who present the particular dilemmas. If it had been thought that it would be a good idea for all the hospitals in Scotland to know what the thinking was, whose job would it have been to make sure that that sort of information is sent round?

A. Well, I suppose it’s a medical policy decision. It perhaps should come from the chief medical officer.<sup>152</sup>

---

<sup>146</sup> Professor Ludlam – Day 54, page 146. See 22.74 regarding the question of when the Scottish directors began meeting as a group.

<sup>149</sup> Ibid page 152

<sup>150</sup> Ibid page 153

<sup>151</sup> Professor Ludlam – Day 55, page 111

<sup>152</sup> Ibid page 62

**22.92** Later, when Professor Ludlam was pressed about this, and it was put to him that these were matters of individual clinical judgement, he highlighted the fact that, from time to time, circulars are produced by the health departments to alert physicians to particular situations, for example in the context of infectious diseases. It was suggested to him that there would be limits to what such guidance could offer:

Q. So if you are thinking of guidance from the chief medical officer, for example, I take it you are not thinking that the chief medical officer will say, "In this instance, use cryoprecipitate; in this instance, use Factor VIII concentrate," or are you anticipating that that sort of level of detail would be prescribed from government?

A. It would be very helpful if the chief medical officers would give that advice.<sup>153</sup>

**22.93** It was suggested to Professor Ludlam both that any such guidance would have to have been obtained by the Chief Medical Officer (CMO) from the haemophilia directors anyway, and that there was in existence the guidance document from December 1984. He maintained his position that more guidance from others on therapeutic policy, would have been helpful. Haemophilia doctors felt that the problem was being 'left at our door'. For them to have had some guidance and 'potentially to address some of the issues that we have been thinking about between England and Scotland by ... the chief medical officers ... might have been helpful'.<sup>154</sup>

**22.94** With these comments having been made by Professor Ludlam, those representing the Scottish Government sought and were granted permission to lodge a response from Dr Iain Macdonald, former chief medical officer for Scotland.<sup>155</sup>

**22.95** Dr Macdonald dissented from Professor Ludlam's view as to what was public policy and what was medical policy. In his opinion, it was the responsibility of the medical profession to evolve treatment policies. This was what the Reference Centre Directors were doing in 1984.

**22.96** Dr Macdonald acknowledged that there was a degree of sensitivity about the boundary between public and medical policies. Decisions about issues on which a CMO should write to his medical colleagues in the NHS lay in this sensitive area. There were circumstances in which it was established and accepted practice for CMOs to write to NHS colleagues. There were two broad categories in which this was normally done. These were: the prevention or limitation of the spread of infectious diseases, and the early detection of disease by screening populations at risk.

**22.97** Concerning Professor Ludlam's proposition that a CMO letter outlining clinical matters would have been helpful, Dr Macdonald concluded:

I have to say that if this had been put to me as CMO, I believe that I would have concluded that the introduction of a government department into an essentially clinical matter being handled by UKHCDO would not have been helpful and probably not acceptable. I would therefore have felt bound to decline.<sup>156</sup>

<sup>156</sup> CMO Letters – Comment by Dr Iain S Macdonald [PEN.018.0620] at 0622

It therefore appears that the provision of guidance on how to treat a person with haemophilia presenting in an emergency was not seen within the Scottish Home and Health Department (SHHD) as a government responsibility.

**22.98** At the time, it might have been understood that haemophilia centres were willing to provide advice to any clinician in Scotland treating a patient with haemophilia. However, it is not clear how non-specialist clinicians would have become aware of guidance issued by the specialist organisation, the UKHCDO, to assist in dealing with a particular problem or how they would have known that a better product might be available in Edinburgh for previously untreated patients.<sup>157</sup> The latter observation also applies to the period after December 1986, when Scottish product more rigorously heated (at 75°C for 72 hours) was released by PFC for clinical trials; it is not clear that hospitals which were not haemophilia centres, or even those which were but which were not involved in the trial, were informed of the availability of this product.<sup>158</sup>

## Discussion

**22.99** The period covered by this chapter was, on any view, challenging for those concerned with the treatment of patients with coagulation deficiencies. The ‘golden interval’, when the introduction and development of factor concentrates appeared to have been an ‘enormous quantum leap’ in therapy, had come to an end with the ‘years of viral contamination problems’.<sup>159</sup> Transmission of HIV, and the consequences of infection with that virus, and growing appreciation of the risks associated with NANB Hepatitis were dominant issues in the middle years of the 1980s. In the light of later experience and research, it seems clear that the development of heat-treated factor products, introduced in Scotland in December 1984, provided effective protection against the risk of transmission of HIV by PFC’s standard concentrates. It would not, however, be clear for some time to clinicians and others dealing with patients that that was the case. In the meantime, increasing understanding of the natural history of NANB Hepatitis was reflected in growing concerns about the use of those concentrates in routine therapy.

**22.100** In attempting to capture the atmosphere of the period, it is necessary to bear in mind that different groups of medical experts and scientists would have different perceptions of risk and benefit from the use of therapeutic products. In addition, government and regulatory agencies, whether involved centrally or at the periphery of developing thought, would reflect, in their response to emerging knowledge, the understanding of their roles at the time. The clinical independence of the practitioner would have been accorded a higher priority than would be conceivable after the formation of the Scottish Intercollegiate Guidelines Network (SIGN) in 1993.<sup>160</sup> There is a need for caution against an assumption that, in the period with which this chapter is concerned, there were simple and uncontroversial answers to questions about the appropriate therapy to adopt, generally or in particular circumstances. The situation was altogether more complex; there were and are no easy answers.

---

<sup>157</sup> Professor Ludlam – Day 55, page 107

<sup>158</sup> See Chapter 24, *Viral Inactivation of Blood Products for Haemophilia Therapy 1985–1987*, at paragraphs 24.132 to 24.137 for details of these events.

<sup>159</sup> Dr Winter – Day 15, page 73

<sup>160</sup> See paragraph 22.116 for further details.

**22.101** A number of issues were focused in questions to be explored in evidence. The first question dealt with the period between the production and introduction of BPL's product 8Y and the development of PFC's product Z8, and was expressed in these terms:

Given that, with effect from Autumn 1985, the Factor VIII concentrate 8Y, produced in England, was more severely heated than the Scottish product, could a supply of 8Y have been obtained to be held for the treatment of any Scottish patients with haemophilia who had received little or no previous exposure to concentrates and who required treatment before the equivalent Scottish product was available?<sup>161</sup>

It is therefore necessary to examine the position concerning the availability of 8Y for Scottish patients.

### *Supply of 8Y for Scotland*

**22.102** The cross-border supply of therapeutic products for routine use for any class or classes of patients raises issues about the general relationships between Scottish fractionators and the SNBTS on the one hand and English fractionators and the NBTS on the other that are materially different from the transfer of materials for specific or limited use. When an official request was made for a limited supply of 8Y, arrangements were made, subject to conditions. Professor Ludlam was also able to obtain some 8Y from Newcastle, he thought probably on a personal approach to the haemophilia director there.<sup>162</sup> In one sense these two events show that, in absolute terms, it was possible to obtain some supplies of 8Y for use in Scotland.

**22.103** The arrangements for the official supply were made after discussion in England. It is significant that in his letter dated 24 July, Mr Pettet records that he has 'spoken to Dr Lane' about the request. It was not treated as a matter of incidental interest.

**22.104** The position generally was that the SNBTS and the PFC had responsibility for meeting the needs of the NHS in Scotland, and the NBTS and the BPL had responsibility for the needs of the service in England and Wales. How that came about is discussed in Chapter 19, *Production of Blood Products – Facilities*. Distribution of therapeutic products in England and Wales was managed on a basis that recognised that the BPL could not satisfy all domestic demand: the regions received the BPL products in proportion to their provision of raw materials. The shortage was particularly significant in the case of 8Y, at least until production facilities could be expanded. Initially, it was expected that output would meet about one third of current demand for concentrate. The arrangements (apart from the special needs of clinical trials to provide information for product licensing purposes) were that Factor 8Y would be issued through Regional Blood Transfusion Centres, unless special provisions existed by agreement for product to be sent direct to the Haemophilia Centre. Allocations to the BTS were to observe the pro rata requirements for distributions agreed between the BPL and the BTS.<sup>163</sup>

<sup>161</sup> List of issues proposed by Inquiry Counsel, 10 February 2012 [PEN.019.0843] at 0854

<sup>162</sup> Professor Ludlam – Day 55, page 120. The Inquiry subsequently learned that this supply appears to have been arranged via Dr Boulton – see letter of 24 August 1987, [PEN.019.1535]. The letter indicates that Dr Boulton was exploring the possibility of obtaining a regular supply of 8Y from England.

<sup>163</sup> Information Sheet, *Dried Factor VIII Concentrate: High-Purity, Heat Treated*, issued to English and Welsh Haemophilia Directors and Regional Transfusion Directors by Blood Products Laboratory, 24 July 1985 [DHF.003.0476]

**22.105** Haemophilia Centre Directors were asked to identify patients ‘at risk’ (patients who were HTLV III antibody negative and who had no history of hepatitis) as potential recipients of the new product. On 15 August 1985 a DHSS circular explained that output of heat treated product (8Y) at the BPL had been increased to the maximum level possible in the current plant.<sup>164</sup> The letter was circulated in England, Wales and Northern Ireland, but not Scotland.<sup>165</sup>

**22.106** Information about the new product was not available uniformly in Scotland. Dr Foster did not know of the information sheet distributed in July.<sup>166</sup> He knew that BPL started issuing 8Y routinely in September 1985 and not before, but he did not know the stage reached in developments at April 1985.<sup>167</sup> In contrast, Dr McClelland who was a member of the Central Committee for Research and Development in Blood Transfusion, and Dr Forrester who attended as representative of the SHHD had information provided at the Committee’s meeting in 19 December 1985 that Dr Rizza had been trialling the product for about nine months.<sup>168</sup> But it was not suggested that either communicated relevant information to Dr Foster. Dr Foster had his own source of information in Dr Smith, but that related to the scientific and development aspects of the product and not to its availability. For other information he depended on Dr Perry. The impression from this evidence was that Scottish officials received information on a casual basis about the new product. They were not involved, as Scottish officials, in the development and distribution of the product, which was consistent with the territorial division of responsibility, and with DHSS policy related to the distribution of 8Y.

**22.107** There is no evidence that the BPL could have provided a significant supply of 8Y to Scotland for the treatment of previously untreated patients (PUPs) in the period 1985–87, or in any event could have done so without detriment to the interests of English and Welsh patients. Given that 8Y was the only HIV-safe NHS Factor VIII concentrate available from the BPL, routine supplies could only have been made at the expense of English and Welsh patients. The reasonable inference from the arrangements made for distribution of what was a scarce resource is that no such supply could or would have been forthcoming. Dr Smith’s expedient of providing a small quantity as an extension of the trial of the product in England and Wales, and the sequence of steps taken before the request was granted, indicate that the actual supply was an exceptional event. For his part, Professor Cash would not have sought any 8Y. He would not have wanted to take a scarce resource from England and Wales where there were severe difficulties.<sup>169</sup> He thought the haemophilia clinicians might have taken a different view and that they might have considered that there should be an approach to England to obtain some.<sup>170</sup> But the basis for that opinion of the haemophilia directors was not clear.

**22.108** The question is hypothetical: the issue was never tested. But the restrictive conditions on the official supply of the 50 vials, and the further arrangement to obtain supplies from Newcastle, added to the official position of the DHSS on actual supplies, indicate that, on balance, a request by the SNBTS or by individual haemophilia clinicians for a share of the BPL product would not have been successful. Whether some kind of barter or exchange could

<sup>164</sup> DHSS circular [DHF.002.5543]

<sup>167</sup> Legal advice to the BPL at that time was to avoid sharing information with the PFC, for intellectual property reasons. Dr Smith – Day 60, pages 62–63.

<sup>168</sup> Minutes of Central Committee for Research and Development in Blood Transfusion, 19 December 1985 [PEN.016.1152]

<sup>169</sup> Professor Cash – Day 157, pages 153–5

<sup>170</sup> Ibid page 156

have been negotiated that might have offered comfort to NBTS Directors adds another layer of speculation. The SHHD or even Scottish Office Ministers might have been asked to intervene with UK counterparts. Possibilities can always be advanced, but it is not possible to conclude that a practicable arrangement could have been arrived at.

**22.109** That is not quite the end of the matter, however, because of the small supply of 8Y (50 vials) which was obtained for Scottish patients in the summer of 1986. As narrated, this was at the behest of Professor Ludlam and the product was not used outwith Edinburgh. Moreover, it appears to have taken place in response to the realisation that a previously untreated patient had contracted NANB Hepatitis from treatment in Edinburgh in May 1986. That this small supply occurred does not demonstrate that a larger quantity could have been obtained. Indeed had the procurement of 8Y been publicised to other haemophilia directors in Scotland, growth in requests for more ad hoc supplies might have been met with refusal. But it is unfortunate that neither the existence of a small stock of product in Edinburgh nor the possibility of obtaining some from England for any previously untreated patient presenting for care seems to have been drawn to the attention of physicians in other areas of the country. Having regard to the way in which arrangements to obtain and store that supply were made, it would have been for the SNBTS, probably through the PFC, with its remit for all of Scotland, to direct attention to this therapeutic option. As Dr Perry himself recognised, he could have written to other Haemophilia Centre Directors and to Regional Transfusion Directors to tell them about the product. It might also have been expected that Professor Ludlam would share information about the supply of 8Y with other haemophilia directors in Scotland.

**22.110** Two other questions were formulated which, in the light of the evidence, are, strictly speaking, superseded. They were (1) whether, if a supply of 8Y could have been obtained for the treatment of Scottish patients with haemophilia who had received little or no previous exposure to concentrates and who required treatment before the equivalent Scottish product was available (other than the small ad hoc supply procured by Dr Perry in the summer of 1986) such a supply should have been procured, and (2) when and by whom should such a supply have been obtained?<sup>171</sup>

**22.111** If it had been possible to conclude that a general supply of 8Y could have been made available, should such a supply have been organised? In the abstract, it certainly appears desirable that a supply of product which seemed likely to offer a greater measure of safety to patients should be achieved. But in practice, the second question, which addresses the mechanics of organising that supply, is more important.

**22.112** There are a number of practical issues that would have arisen if there had been an attempt to convert the hypothesis into reality. Obtaining a national supply would not have been a task for Dr Ludlam: his attention was focused on providing for the needs of patients in or attached to the Edinburgh centre. It appears that it would not have been thought to be within the responsibility of the SHHD or the CMO because they did not interfere in clinical matters. It might have been considered to be within the remit of the SNBTS to procure a supply for Scotland, although it is not clear by whom such an initiative could have been taken. On one view, it would not have been Dr Perry's responsibility to make the request: his sphere of responsibility was the production of NHS concentrates for patients in Scotland. On the other hand, he did envisage that the PFC would have been an appropriate channel for requesting material.

---

<sup>171</sup> List of issues proposed by Inquiry Counsel, 10 February 2012 [PEN.019.0843] at 0854

**22.113** For England and Wales, the DHSS had a role in questions of supply: it appears clearly to have been their decision that restricted the general availability of 8Y to England, Wales and Northern Ireland, and targeting of particularly vulnerable patients was an aspect of that decision. Only the SHHD could have played a role in securing an adjustment of that policy for the benefit of similar vulnerable patients in Scotland.

### *Guidance for treatment of patients*

**22.114** The next question that arose was whether, in the absence of a supply of 8Y to treat patients with little or no previous exposure to concentrates, the general approaches to blood product therapy for haemophilia in Scotland in the period 1985 to 1987 were reasonable.<sup>172</sup>

**22.115** Patient core participants have submitted that there was a failure to make provision for a sophisticated system to identify those who might be previously untreated patients with coagulation issues should they present for medical care (apparently at any level, general practitioner, health centre, or hospital).<sup>173</sup> The general care of patients who have or may have coagulation defects, is not within the Terms of Reference. There was, however, no evidence of a general issue that could have been dealt with systematically. There was no evidence that it would have been practicable to treat every patient who was not already receiving care as a haemophilia patient as potentially suffering from a coagulation defect.

**22.116** Turning to more general questions of what ought to have been available by way of guidance, the objective of SIGN shows that in relation to clinical practice there was soon to be recognised a need for general guidelines. The objective of the organisation is:

The Scottish Intercollegiate Guidelines Network (SIGN) was formed in 1993. Our objective is to improve the quality of health care for patients in Scotland by reducing variation in practice and outcome, through the development and dissemination of national clinical guidelines containing recommendations for effective practice based on current evidence.<sup>174</sup>

**22.117** It is clear that such guidelines are not perceived to threaten and do not threaten clinical independence. Indeed, the initiative for the formation of SIGN came from the Scottish Medical Royal Colleges.<sup>175</sup>

**22.118** At this point, the dilemma confronting haemophilia clinicians continued to be whether to use concentrates although they knew that concentrates exposed the patient to risk of transmission of hepatitis viruses. As knowledge of the natural history of NANB Hepatitis developed, the balance in perception of risk/benefit inevitably changed. On one side of the equation, the natural history of haemophilia remained as it always was: the risk of bleeding that could extend to fatal bleeding into the gut or brain, and, short of that, could lead to the development of disabling disease of the joints, among other consequences. Haemophilia remained a serious and often life-threatening condition requiring treatment.

<sup>175</sup> McAlister G, The Scottish Intercollegiate Guidelines Network (SIGN), *Guidelines in Practice*, Vol 4, No 10. [http://www.equidelines.co.uk/equidelinesmain/gjp/vol\\_4/oct\\_01/macalister\\_sign\\_oct01.htm](http://www.equidelines.co.uk/equidelinesmain/gjp/vol_4/oct_01/macalister_sign_oct01.htm) last accessed 17 June 2014.

**22.119** Against that background, it would be reasonable to suggest that the clinician would use the least damaging product that was available to him or her for effective treatment of the particular manifestation of the underlying disease that the patient was experiencing at the time.

**22.120** That appears, generally, to have been the approach reflected in the guidelines, dated 14 December 1984, prepared by Professor Bloom and sent to Regional Directors: *Haemophilia Centre Directors Organisation AIDS Advisory Document*.<sup>176</sup> Although expressed primarily as guidance related to AIDS, then the most significant threat envisaged, it was more general in its approach. Available therapeutic materials were listed in order of safety, and the risk of NANB Hepatitis was specifically mentioned. The UKHCDO view was expressed that bleeding was the commonest cause of disability and death, and that concentrate was still needed. The use of DDAVP was recommended in appropriate cases. And where concentrates were needed, advice was tendered as to the priorities to be observed.

**22.121** It was reasonable for haemophilia clinicians to follow this guidance in practice. Professor Lowe said that the advice was followed in Glasgow. Professor Ludlam based his practice in Edinburgh on the advice. So far as that advice was followed, it provided a reasonable underpinning of clinical practice in Scotland. The evidence of Professor Ludlam and of Professor Lowe that the policy of their respective centres was to follow the UKHCDO advice is accepted.

**22.122** However, that led inevitably to a question whether the arrangements for the dissemination of general guidance to clinicians regarding haemophilia treatment during this period were satisfactory.

**22.123** In some respects this is the more fundamental question. There may be little point in a small number of senior clinical consultants knowing a system, including any guidelines incorporated in it, if (a) their associates and subordinates and (b) clinicians outwith a narrow core of specialists (of which those senior clinical consultants are the characteristic members) do not know of the guidance and are not equipped to follow it.

**22.124** There has to be a mechanism within a system of practice that ensures, so far as reasonably practicable, that guidance is disseminated as required to inform all practitioners likely to be called on to minister to patients' needs, and that ensures appropriate compliance with what is regarded as best practice from time to time. No system can anticipate, far less resolve, all of the issues that may arise in clinical practice. As Professor Ludlam observed, an over-prescriptive system that stipulated for the use of DDAVP in treating a mildly affected haemophilia patient would be counter-productive in the case of a patient who had had a serious road traffic accident. Emergencies will always demand ad hoc decisions adapted to patients' needs. A clinician faced with a patient in extreme pain may prescribe treatment that would normally be contrary to recommended practice if satisfied that the course is necessary to secure the patient's safety, for example, and nothing else is available. However, in this as in other circumstances, elaboration of exceptions tends to underline the need for the basic rule.

---

<sup>176</sup> *Haemophilia Centre Directors Organisation AIDS Advisory Document*, 14 December 1984 [SGF.001.2388]

**22.125** Two questions arise: were there basic guidelines, and who was responsible for disseminating them? Looking at the needs of Scotland as a whole, there clearly were not basic guidelines for general application. The UKHCDO guidelines prepared by Professor Bloom were addressed to a particular group of recipients who could be expected to understand the complex background and to be familiar with the issues implicit in the advice given. They were not designed for, and would have been less easily understood by, a general practitioner holding an occasional clinic in a remote cottage hospital. In one of the two instances of which the Inquiry has notice, an island hospital held a supply of PFC factor concentrate. Other outlying units might well have held such therapeutic materials. The need for guidance seems obvious – even if only to alert non-specialist physicians to the dilemmas arising in therapeutic decisions at this time, and the need to take advice.

**22.126** The need for guidance extends beyond directions on reconstituting or otherwise preparing therapeutic materials for use. Taking a patient’s informed consent to the use of therapy requires that the clinician is equipped with information on the risk/benefit balance of the use of the particular product, and both understands and has the advice necessary to communicate relevant issues to the patient.

**22.127** These issues were probably not peculiar to haemophilia – they must have been relevant to other chronic conditions as well. The needs of small local hospitals or GPs in remote areas had to be considered and they should have been kept ‘in the loop’ of thinking. On the evidence available to the Inquiry, there was no such guidance.

**22.128** This was a period in which there was increasing understanding that it was almost certain that patients treated for the first time with factor concentrates, or with little previous exposure, would be exposed to NANB Hepatitis infection on first receiving an infusion of any concentrate other than those most severely heat treated. There was a clear need for central direction and advice on the approach properly to be adopted to the use of available products and the implications for patients of their use.<sup>177</sup>

**22.129** By today’s standards, the arrangements appear very vague. Relying heavily on observations by Professor Thomas, the patient interest core participants have submitted:

The evidence available to the Inquiry suggests ... that little formal structure existed to ensure that important information and opinions about the risks of transmission of NANB hepatitis to uninfected patients, the known severity of the disease, what treatment options were available and how treatment decisions might be affected by this information was conveyed clearly and efficiently to anyone other than the most senior staff at Scottish haemophilia reference centre[s] (ie Edinburgh and Glasgow). In particular there would seem to be little evidence of formal efforts being made to communicate any such information to junior staff or to hospitals where such treatment decisions may have to be made outwith these main centres.<sup>178</sup>

**22.130** The vertical dissemination of information within hospitals is discussed below. Otherwise, the submission is generally well founded. It is not appropriate to place as much reliance on the evidence of Professor Thomas in this regard as is set out in the patient core participants’ argumentation in support of the submission: he was not and is not a

---

<sup>177</sup> Patient interest core participants: Submissions for the C3A Topic [PEN.019.0657] at 0663–64

<sup>178</sup> Ibid [PEN.019.0657] at 0670–71

haemophilia clinician and this was not his field.<sup>179</sup> But these points do not detract from the general validity of the submission.

**22.131** There was no guidance from central government agencies, from the SHHD or the CMO. Irrespective of whether departmental involvement in the content of such guidance would have been appropriate,<sup>180</sup> it is unsatisfactory that the only facilities equipped with guidance were haemophilia centres, which had the material distributed by the UKHCDO. Patients with haemophilia needing emergency treatment could present at any casualty department in the country. Representatives of the SHHD were involved as members of or as in attendance at meetings of representatives of clinicians, scientists and medical members of the SNBTS. If it were accepted that it was inappropriate for them to participate in or guide discussion,<sup>181</sup> they nevertheless remained a conduit for the communication of information to government and had a distinct role in advising on the financing of research and development across a broad front. It would have been for the SHHD to arrange for the distribution of guidance to the NHS in Scotland as a whole. There was already a precedent for government involvement in delivery of haemophilia care in England and Wales in the shape of a DHSS Circular Family Practitioner Notice addressed to general medical and dental practitioners in January 1976, concerning revised arrangements for the care of persons suffering from haemophilia and related conditions.<sup>182</sup> According to that Notice, the functions of haemophilia centres included giving advice to general practitioners about the emergency treatment of haemophilia patients on their list. This Notice was appended to a DHSS Health Circular dated February 1976, addressed to Regional Health Authorities and Family Practitioner Committees for action, and to Area Health Authorities and Boards of Governors for information.<sup>183</sup> Whilst the Notice does not appear to have been formally circulated in Scotland, it was referred to and appears to have reflected the arrangements for haemophilia care in Scotland as well as in England and Wales.<sup>184</sup> It was, in any event, an indication of what was thought appropriate for a central government department to do in the field of haemophilia care. Although the 1976 document was a Circular and not a CMO letter, it did specify what sort of care was to be provided by a haemophilia centre and by a reference centre. Moreover, the need for a haemophilia centre to provide guidance to general practitioners on the emergency care of patients with haemophilia was specifically referred to. It did not mention providing guidance to ‘local’ hospitals, which might also be required to provide emergency care and, in that regard, may have been incomplete. But it illustrates a desire on the part of central government to establish and maintain a coherent system for the provision of care for people with haemophilia.

**22.132** In another context, the Inquiry has noted the intervention of Dr Yellowlees, CMO, England and Wales, in May 1975 in a debate over the collection of blood donations in prisons, a matter otherwise considered to be within the responsibility of Regional Transfusion Directors.<sup>185</sup>

<sup>179</sup> Professor Thomas’s evidence at Day 52, pages 155–163 is general and rather second hand.

<sup>180</sup> The appropriateness of involvement was disputed by the Scottish Government in its closing submissions [PEN.019.0274] at 0278 and 0335

<sup>181</sup> As was submitted by the Scottish Government in its closing submissions PEN.019.0274 at 0278 and 0335

<sup>182</sup> Family Practitioner Notice FPN 105 (HC(76)4) *Organisation of Haemophilia Centres* January 1976 [DHF.002.4280]

<sup>183</sup> Health Circular HC(76)4 *Arrangements for the care of persons suffering from haemophilia and related conditions*, and accompanying memorandum February 1976 [DHF.001.2747] and [DHF.002.4280]

<sup>185</sup> See Chapter 26, *Donor Selection – Higher Risk Donors*, paragraphs 26.79 to 26.80

**22.133** Efficient and effective provision for the care of vulnerable populations such as those with coagulation deficiencies is not a matter that should depend on narrow definitions of departmental or agency competency or their individual remits: responsibility rests ultimately with government as a whole. Ministers control budgets, subject to Parliamentary oversight. Whoever proposes, Ministers dispose in the funding of work in the national health sector. As a practical matter, the overall shape of the service, as distinct from clinical care of a particular patient, is the responsibility of central government departments and associated agencies. That responsibility shifts among departments and agencies as circumstances demand: there are few immutable principles that dictate current competencies and provide insuperable barriers to the resolution of issues affecting public health. Nor should there be. Any doubts about the competency of the health departments to issue guidance in this particular area would have been resolved had a challenge arisen.

**22.134** The second aspect of this question relates to vertical dissemination of advice and instruction. It arises on the hypothesis that a particular hospital or other operating division of the service has available sources of advice and information at some, typically senior, level, and the question focuses on the approach adopted to the dissemination of that information and advice down through the particular organisation or part of the organisation concerned with immediate patient care.

**22.135** The patient interest core participants submitted in this regard that:

- Minimally treated patients included those who had received treatment in the past for their bleeding disorder, but not with factor concentrates or with large volumes of cryoprecipitate.
- The treatment of virgin and minimally treated patients over this period merited special consideration by treating doctors on the basis that (a) the state of knowledge was such that it was highly likely if not certain that they would be infected with a potentially lethal disease if treated with the then available Scottish factor VIII concentrate (NY) and (b) it was probable that such patients would not yet be infected with that disease.
- The then available Scottish factor VIII concentrate should not have been given to virgin or minimally treated patients over this period unless it was unavoidable.
- The priority in the treatment of bleeding episodes in such patients should have been to try to achieve haemostasis with other treatments which carried less of a risk of transmission of NANB hepatitis, such as DDAVP (for mild patients) or cryoprecipitate or alternative products sourced outside Scotland before resorting to the use of SNBTS factor VIII concentrate.<sup>186</sup>

**22.136** The third point is well made, against the background of the narrative in the first and second points, since it appears to recognise the need for clinical judgement. The fourth point is over-prescriptive and inappropriate. It is not for this Inquiry, nor would it have been appropriate for any general guidance, to dictate an order of treatment relating to the patient's underlying coagulation deficiency without regard to the circumstances requiring medical attention. Professor Ludlam's evidence relating to the use of DDAVP to treat a patient with a mild coagulation disorder following severe trauma, already referred

---

<sup>186</sup> Patient interest core participants: Submissions for the C3A Topic [PEN.019.0657] at 0678

to, illustrates that conclusively. However appropriate for routine purposes, DDAVP would be wholly inappropriate for a patient who was bleeding severely after a road traffic accident.

**22.137** Professor Ludlam gave evidence about the arrangements in his department in Edinburgh. For present purposes this is but one example, and as such illustrates what could happen during the material period.

**22.138** It is, however, difficult to derive a clear picture of the situation in Edinburgh at that time. Professor Ludlam's evidence frequently consisted of informed speculation about what would have been the position or must have been the position, without direct recollection of events as they happened. This perhaps followed necessarily from the passage of time and the lack of contemporaneous records and forms that might have been in use. The unsatisfactory nature of the evidence can best be illustrated by his change in position relating to written guidance to casualty staff on handling patients with haemophilia or potential haemophilia. He clearly had thought about his evidence after the first occasion on which he spoke of this subject, and, with the benefit of that, he changed position. It can be accepted that his revised evidence is reliable. But it does not resolve all difficulty. According to his revised evidence, there was a meeting every two to three years between haematology and casualty officers to update the guidance sheet issued from haematology. At any one time, therefore, almost three years might have elapsed since the guidance was last updated. During the period with which this chapter is concerned, the emphasis on seeking advice from the haemophilia clinicians or the haematology department generally would have been expected to have changed. The need to involve specialists to ensure an appropriate selection and use of coagulants would have required greater emphasis.

**22.139** Within his department, Professor Ludlam conducted weekly tutorial sessions. That was an appropriate course of action. But it might best have been supported by notes for reference in the course of clinical practice. Reliable recollection of what is said at such sessions cannot be assumed generally, and certainly cannot be assumed in the context of an anxious response to the needs of a patient who might be in extreme need of immediate therapy. More precise protocols, including a requirement to refer issues to senior colleagues for definitive advice, would have been desirable. Without written guidance, there was inevitably a risk that junior staff, who might be satisfied that they knew the correct course of action, might act in a way that was inconsistent with the views of more senior colleagues.<sup>187</sup>

**22.140** As observed by the patient interest core participants,<sup>188</sup> it is implicit in Professor Ludlam's evidence that it would have been beneficial (for him) to have had guidance from the CMO or government department, and that it would have been at least as beneficial for clear guidance to have been provided in turn for more junior members of his department.

**22.141** The patient interest core participants have made a specific submission in these terms:

[I]nadequate steps were taken in light of the infection of a virgin patient in May 1986 in Edinburgh with NANB hepatitis to avoid a re-occurrence of this infection in similar patients around Scotland.<sup>189</sup>

---

<sup>187</sup> It is odd that there was no update of UKHCDO guidance between December 1984 and May 1988. But that would not bear on the need in Scotland to reflect in guidance changing knowledge of the effectiveness and relative infectivity of products.

<sup>188</sup> Patient interest core participants: Submissions for the C3A Topic [PEN.019.0657] at 0679

<sup>189</sup> Ibid [PEN.019.0657] at 0689

**22.142** As previously observed, the Inquiry had notice of two cases of transmission of NANB hepatitis to previously untreated patients in the relevant period, 1 September 1985 to 30 June 1987. There was no evidence available to the Inquiry of transmission of infection other than in the two known cases. It is not within the Inquiry's Terms of Reference to investigate specific cases other than as required to illustrate or inform general discussion. But the circumstances in which these patients were treated (one at night, without the involvement of the most senior haemophilia clinicians and the other in a remote part of Scotland) are precisely the sort of situations in which the need for up-to-date written guidance on the risks of NANB Hepatitis and the relative risks and benefits of the therapeutic products available was most pressing.

## **Conclusions**

### *Availability of 8Y*

**22.143** The distribution of 8Y in England, Wales and Northern Ireland was strictly controlled under agreements between the BPL and the NBTS that provided for distribution of finished products pro rata to regions' supplies to the BPL of raw materials for fractionation.

**22.144** It cannot be concluded on the evidence available that a barter or other arrangement could have been negotiated that might have procured a supply of 8Y for use in Scotland in exchange for reciprocal supplies of PFC products.

**22.145** For these reasons, it is highly unlikely that regular supplies of 8Y would have been made available for use in Scotland.

**22.146** It is the case, however, that BPL 8Y appears to have been available for use in Scotland on request in very limited quantities in exceptional circumstances at least from the middle of 1986.

**22.147** A request for 8Y to treat a Scottish patient with haemophilia who had received little or no previous exposure to concentrates and who required treatment before the equivalent Scottish product was available was likely to have been successful if treated as part of the field trial of the product or if made ad hoc to satisfy particular and specific requirements of the patient's management acceptable to the BPL and the NBTS.

**22.148** Once the arrangement for limited supplies of 8Y had been made in the summer of 1986 at the initiative of Professor Ludlam, no steps were taken to inform medical practitioners, in particular haemophilia treaters, that supplies of BPL 8Y might be procured even on a limited basis. There was accordingly a failure to provide information that could have informed clinicians of the possibility of obtaining access to the product in appropriate circumstances.

**22.149** In addition, no steps were taken to draw to the attention of physicians outwith Edinburgh the fact that there was already a small stock of 8Y held there.

### *Blood product therapy in Scotland: 1985–87*

**22.150** UKHCDO's guidelines, dated 14 December 1984 and distributed as the 'Haemophilia Centre Directors Organisation AIDS Advisory Document', provided reasonable guidance for haemophilia clinicians to follow in practice in this period.

**22.151** Those guidelines were distributed to Haemophilia Centre Directors. They were followed in Glasgow and Edinburgh, and probably at other Regional Haemophilia Centres with haemophilia directors.

**22.152** There is, however, no evidence of the distribution of any guidance to practitioners in hospitals in Scotland which did not have haemophilia centres, who might find themselves dealing with a person with haemophilia in an emergency, on the use of blood products in coagulation disorder therapy.

**22.153** It would have been the responsibility of the SHHD to have arranged for the provision of appropriate guidelines, probably in consultation with the UKHCDO and the Scottish haemophilia clinicians.

**22.154** There is no substance in the suggestion that the issue of such guidelines by the SHHD would have infringed clinical independence in the management of individual patients.

**22.155** Although guidelines for the service as a whole were less common in the period 1985–87 than they subsequently became, the principle of departmental guidance concerning the system of care for patients with haemophilia was established by 1976.

**22.156** Guidance within institutions was a matter for the senior clinician in charge of haemophilia care and patient management.

**22.157** Such guidance, in writing, was necessary, and it was necessary for it to be amended and updated as information available about therapeutic products, their effectiveness and likely side-effects changed with developing knowledge of the diseases to be treated.

**22.158** Scottish Haemophilia Directors had no administrative authority to impose an obligation on each other or on clinicians in charge of haemophilia care in general hospital units to follow any such written guidance.

## CHAPTER 23

### VIRAL INACTIVATION OF BLOOD PRODUCTS FOR HAEMOPHILIA THERAPY UP TO 1985

#### Introduction

**23.1** It had been known, internationally, since the mid-1940s that transfusion of blood and blood products carried a risk of transmission of infectious agents.<sup>1</sup> Identification of the agents giving rise to risk, and understanding of the natural history of infections resulting from transmission developed over time. The general nature of the risk was understood by fractionators when coagulation factor concentrates were developed in their modern form in the early 1970s.

**23.2** This chapter examines the efforts of the Protein Fractionation Centre (PFC) in Edinburgh, in the period up to 1985, to inactivate viruses (initially hepatitis viruses and later HIV) which were present in its Factor VIII and Factor IX concentrates in this period. It describes how scientific, technical and practical difficulties in bulk production of Factor VIII and Factor IX concentrates were overcome, enabling the PFC to introduce heat-treated Factor VIII concentrate in December 1984 that was effective in controlling transmission of HIV, with more stringent heat-treating protocols developed thereafter, and heat-treated Factor IX concentrate – HT-DEFIX – in May 1985. Inactivation of the Hepatitis C virus is discussed in Chapter 24, *Viral Inactivation of Blood Products for Haemophilia Therapy 1985–1987*.

**23.3** Superficially, the problems related to viral contamination of blood and its derivatives and viral inactivation of blood products can be expressed simply. Blood (and specifically blood plasma) can be a vector for human viruses, and can result in blood products manufactured from such plasma also being infective.<sup>2</sup> The aim behind viral inactivation is to remove or destroy such viruses – using heat, chemicals, radiation, or a combination of these – and so to make blood products safe for human use.

**23.4** However, inactivating viruses in blood products proved to be extremely complex, scientifically, technically and on a practical level. Blood is chemically complex, as are the viruses it harbours. Technical issues can and did arise in ensuring that the active element in a blood product (for example Factor VIII) was not also destroyed or damaged along with any virus. The inactivation of viruses can also increase the cost of a product – making it economically unattractive – and can impact negatively on the resultant yield.<sup>3</sup> These factors can affect the likelihood that demand for a given product can be met. In addition, where a virus has yet to be identified, it can be difficult to establish with certainty that a given inactivation process has been successful. As discussed in this chapter, the PFC was confronted by these and other practical issues when attempting to inactivate non-A, non-B (NANB) Hepatitis and HIV in the period up to 1985.

---

<sup>1</sup> Maunsell, 'Transmission of hepatitis during blood transfusion', *British Medical Journal*, 1 December 1945; 783 [LIT.001.0246]

<sup>2</sup> As explained elsewhere in this Report, the risk of infectivity rises where large plasma pools are used as the source material for a given blood product.

<sup>3</sup> In the case of Factor VIII, the amount of Factor VIII activity recovered from a given quantity of frozen plasma.

## Historical background

### *Albumin*

**23.5.** The Cohn fractionation process was a key step in the manufacture of human blood products. An important goal behind Cohn's research was to develop a product which could act as a substitute for human plasma in the treatment of wartime casualties.<sup>4</sup> Albumin provided the solution. It was crucial that albumin for military use remained stable ('undenatured' in technical terms) under battlefield conditions. According to John Edsall, who was involved in Cohn's original research:

We knew that the albumin would be sent all over the world, including regions of intense heat such as the north African desert or the southwest Pacific. It had to remain undenatured by exposure to heat for months, indeed for years, if it was to serve its purpose.<sup>5</sup>

**23.6** Human plasma proteins tend to become damaged and lose effectiveness when temperatures are raised, and this presented a practical problem. As outlined in Dr Peter Foster's paper on heat treatment:

Human proteins in their natural state exist at body temperature and are prone to damage at raised temperatures. Proteins removed from their natural environment may be even more susceptible to heat induced damage, either from heat directly or from an increase in the activity of substances, such as enzymes, which can degrade proteins. Heat causes proteins to denature and become insoluble (e.g. cooked vs. uncooked egg white) and can occur at modest temperatures, well below the boiling point of water, with different proteins differing in their ability to withstand heat.<sup>6</sup>

**23.7** Research into techniques for improving the ability of albumin to withstand heat led to the discovery by Dr J Murray Luck in 1944 that the addition of chemicals known as 'stabilisers' could enhance albumin's thermal stability with the result that it could be heated for a longer period at a higher temperature before breaking down.<sup>7</sup> Further research focused on destroying bacterial contaminants. This work showed that pasteurisation (heating in solution) was possible and an albumin product which was pasteurised for 10 hours at 60°C was introduced in the USA from June 1945.<sup>8</sup> While albumin was the principal application of pasteurisation, other proteins, Antithrombin 3 and Factor XIII were also pasteurised with appropriate stabilisers.<sup>9</sup> Pasteurisation as a process was not specific to these applications in the pharmaceutical industry. It was established technology in the food industry where it was necessary to reduce or remove microbiological contaminants (for example in milk).<sup>10</sup>

<sup>9</sup> Dr Smith – Day 59, pages 47–49

<sup>10</sup> Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1763–64

**23.8** Awareness that hepatitis could be transmitted by transfusions of blood plasma was, in Dr Foster's view, the reason for Dr Edwin J Cohn recommending studies to assess whether 'serum hepatitis' (blood-borne hepatitis) could be transmitted by albumin which had been pasteurised for 10 hours at 60°C (or whether other heating conditions were needed).<sup>11</sup> These studies involved treating patients with heat-treated albumin which had been spiked with, or derived from, plasma which was known to be infected with hepatitis. The results suggested that pasteurised albumin did not transmit blood-borne hepatitis virus(es).

**23.9** Further studies in the 1970s, following the discovery of the Hepatitis B virus, demonstrated, firstly, that the Cohn fractionation process itself physically removed most of the Hepatitis B virus from albumin before pasteurisation. Albumin was produced from Fraction V, the final stage in the fractionation process. Virus in the source plasma was removed differentially at the successive stages of the process, reducing the virus load before the application of heat. Secondly, it was discovered that pasteurisation alone was insufficient to destroy the Hepatitis B virus. It was the combination of fractionation and pasteurisation which was effective in inactivating the Hepatitis B virus in the albumin solution.<sup>12</sup>

**23.10** By the 1970s the combination of cold ethanol fractionation and pasteurisation for 10 hours at 60°C was thought to be effective in inactivating hepatitis in albumin. There had been only one documented example of a Hepatitis B outbreak connected to the production of albumin and this was shown to have related to the incorrect bulk pasteurisation of the product, Plasma Protein Fraction (PPF), rather than to any inherent defect in the established heating protocol.<sup>13</sup> PPF was albumin of slightly reduced purity. Given its apparent safety, pasteurisation for 10 hours at 60°C became the recommended procedure for the treatment of albumin.<sup>14</sup>

**23.11** By the time the Hepatitis C virus (HCV) had been identified in May 1988, it was recognised that the most promising approach to the reduction of transfusion-associated disease was the combination of biophysical removal and biochemical inactivation of virus.<sup>15</sup> The characterisation of the Hepatitis C virus was incomplete, however, and it was not possible to culture the virus. But enough was known to enable the identification of viruses sufficiently similar in structure for experimental purposes. It became possible to carry out experiments which tested the degree to which the Cohn fractionation procedure and pasteurisation physically removed and/or inactivated Hepatitis C in various blood products using similar 'model' viruses as proxies for Hepatitis C.<sup>16</sup> The procedure followed was to spike product with virus and to test by assay the degree to which the virus had been removed by fractionation or destroyed by heat treatment (so-called 'validation studies').<sup>17</sup> These studies had various strands, but the key conclusions were as follows:

<sup>16</sup> See Professor van Aken – Day 2, pages 29–33 for a discussion of culturing and the use of model viruses.

<sup>17</sup> For more information on virus spiking and Hepatitis C see Professor van Aken's report on Stable Plasma Protein Solution and the transmission of HCV [PEN.001.0306] at 0307

- The Cohn fractionation process did not lead to the Hepatitis C in the original plasma being spread evenly among the resulting protein fractions. Most Hepatitis C was to be found in cryoprecipitate. The least amount was found in the fractions from which albumin is derived.<sup>18</sup>
- Pasteurising albumin for 10 hours at 60°C inactivated Hepatitis C and HIV to a level which could be considered safe.<sup>19</sup>

**23.12** Work on heat-treating albumin highlighted the vulnerability of human plasma proteins to damage when temperatures are raised, but also demonstrated that chemical stabilisers could be used to protect proteins from the effects of heat. In addition, it was demonstrated that the effectiveness of fractionation, with or without viral inactivation, to remove or eliminate virus infection could be tested by validation studies using model viruses. These factors came to be of general relevance as research into viral inactivation of blood products progressed.

### *Factor concentrates*

**23.13** Although using chemical stabilisers to pasteurise albumin for 10 hours at 60°C was regarded as successful in inactivating the hepatitis virus, it was widely understood that this approach could not simply be replicated for coagulation factors.<sup>20</sup> Dr Foster's views on the position reached at the beginning of the 1980s are summarised briefly at the end of Chapter 20, *Haemophilia Therapy – The Period up to the Early 1980s*. It is necessary to discuss them in greater detail. The coagulation factors are more 'heat labile' than albumin. They are more easily destroyed or damaged by heat.<sup>21</sup> Finding chemical stabilisers capable of protecting factor concentrates against heat sufficient to inactivate viruses was not straightforward.

**23.14** As noted in Chapter 20, *Haemophilia Therapy – The Period up to the Early 1980s*, among other reasons, Dr Foster's views were influenced by early SNBTS research that had provided evidence to support the generally accepted view that Factor VIII was temperature sensitive.<sup>22</sup> Collaboration with Dr Alan Johnson, New York University, during the 1970s, included development of the PFC's intermediate purity Factor VIII concentrate. One aspect of this research related to the filtration of the final solution to remove impurities. A very fine membrane filter (0.22 micrometre) was used, with the solution at a temperature of 20°C. This was found to lead to a loss of Factor VIII activity. Dr Johnson suggested raising the temperature of the solution to increase solubility and speed up filtration. The manufacturing process was changed: the temperature at filtration was raised from 20°C to 30°C. There was an even greater loss of activity. According to Dr Foster:

These observations confirmed that factor VIII activity could be destroyed by even a modest increase in temperature and it seemed inconceivable that factor VIII could be heat treated at a temperature high enough to eliminate the risk of hepatitis transmission.<sup>23</sup>

<sup>23</sup> SNBTS Briefing Paper on the Development of Heat Treatment of Coagulation Factors [PEN.013.1309] at 1340

**23.15** In his witness statement Dr James Smith expanded on this point. Factor VIII is a much larger molecule than albumin, a relatively small protein. Because of its size and complexity, Factor VIII is possibly the worst candidate among coagulation factors for heat treatment. Factor VIII activity requires that the entire molecule retain its structure intact. Bonds in the molecule are easily broken by heat. Enzymes in plasma also destroy activity. Calcium, on which the integrity of the molecule depends, is readily removed by some of the solutions used in processing. Processing had to be as fast and cold as possible. It did not come naturally to a fractionator, used to handling Factor VIII with extreme sensitivity ('with kid gloves' in Dr Smith's words), to place a dry preparation into an oven at 80°C or to place a solution in a water bath at 60°C. Dr Smith added:

Unlike albumin, there is no fortunate short-cut to protecting Factor VIII (and most other plasma proteins) against heat. They need to be protected by high concentrations of salts, amino acids or sugars, at far higher than physiologically-tolerable concentrations. These protectants then have to be removed in later stages which can be quite demanding and likely to lose yield. It transpires that for Factor VIII, the preferred protectants are sugars and glycine, which at the high concentrations used make a sticky solution, difficult to work with at large scale. Even after pasteurisation, the common methods for recovering a small amount of protein from a large volume of viscous liquid were challenged to the limit in the early 1980s. In addition, these post-heating manipulations must be done in an expensive, controlled environment to avoid recontamination; there is no question of pasteurising in the final container.<sup>24</sup>

**23.16** Dr Smith said that fractionators resisted almost viscerally the application of high temperature to Factor VIII.<sup>25</sup> It is important to emphasise the implications of some of the points made. Protectants were essential in the course of heat treatment, but at concentrations that required their separation from the Factor VIII proteins after heating. It was not possible, therefore, to pasteurise the final freeze-dried Factor VIII product in vial. If freeze-dried Factor VIII was to be heat-treated to inactivate virus contamination, it would require significantly different technology from pasteurisation.

#### *Other obstacles to early progress with virus inactivation of factor concentrates*

**23.17** In addition to the challenges of heat treatment, in the period up to 1980 various other obstacles lay in the path of successfully inactivating viruses in factor concentrates.<sup>26</sup> There was a lack of common understanding of the problem of virus transmission. Dr Smith drew a distinction between haemophilia clinicians and patients on the one hand and fractionators on the other in this period.<sup>27</sup> Whether or not his assessment of the position was correct or fair, he had a clear perception that those concerned with the manufacture of therapeutic products had a distinctive appreciation of the risks of transmission of virus infection. As he saw it, there was little pressure from clinicians and patients to take viral hepatitis seriously in this period. The view that NANB Hepatitis could have severe long-term consequences was not widely held. (As discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*, the risk of progression to serious disease was not generally

<sup>24</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1568–69

<sup>25</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1567

<sup>26</sup> For these and other obstacles identified, see: Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1567; SNBTS Briefing Paper on the Development of Heat Treatment of Coagulation Factors [PEN.013.1309] at 1323–24; and Professor van Aken's statement on the introduction of dry heat treatment of Factor VIII concentrate [PEN.012.1932] at 1932

<sup>27</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1554

appreciated until the second half of 1985.) By 1980, the risk of Hepatitis B transmission was thought to have been tamed by donation testing, and it was expected that a vaccine would soon be available. He said that it took AIDS to get the attention of the majority of haemophilia treaters and patients on to blood-borne viruses.

**23.18** When the SNBTS and Haemophilia Directors met on 30 January 1981 (for the first time since 1977) the topic of virus inactivation was not mentioned.<sup>28</sup> By that point, it was known to Professor John Cash and PFC scientists that Behringwerke AG had claimed that it had succeeded in pasteurising Factor VIII, though information on the company's work had yet to be published in any scientific journal that was widely available.<sup>29</sup> So far as the record shows, the information was not shared with the transfusionists and haemophilia specialists present on 30 January 1981.

**23.19** Fractionators were, in Dr Smith's view, much more concerned about NANB Hepatitis than other specialists: in his words, they could see their entire industry going down the tubes unless they did something about the threat.<sup>30</sup> The agent of transmission of NANB Hepatitis was a very recalcitrant virus, with no convincing markers until the end of the decade. There were very few tools, especially for proving whether any attempt at inactivation had succeeded. Scientists were also misled by persistent claims that there might be more than one NANB Hepatitis virus.

**23.20** Having regard to the evidence of Dr Smith and Dr Foster (and of Professor Willem van Aken at paragraphs 23.220 to 23.227 below), the obstacles to technological progress which they would have perceived in about 1980 were:

- NANB Hepatitis was widely perceived to be a mild, transient illness with only very rare serious sequelae.<sup>31</sup>
- It was widely believed that NANB Hepatitis was transmitted by voluntary blood donations much less frequently than by plasma from paid donors, which was the predominant component in the large pool products of commercial fractionators.<sup>32</sup>
- There was no credible marker or screening test for NANB Hepatitis, at the stage of donation or in the course of manufacture.
- At the time, understanding of the nature and structure of the Factor VIII molecule and related proteins was limited.<sup>33</sup>
- There was a lack of knowledge of the agent responsible for NANB Hepatitis and the lack of a marker for NANB Hepatitis precluded spiking and validation studies to test the efficacy of a given viral inactivation procedure.<sup>34</sup>
- The only way to confirm infectivity in a concentrate was to inject it into three previously untreated chimpanzees, an endangered species. The chimpanzee model was ultimately unreliable in predicting whether a heat-treated product was potentially free from NANB Hepatitis.<sup>35</sup>

<sup>28</sup> Minutes of meeting [SNB.001.5055]

<sup>29</sup> See paragraph 23.33 below

<sup>32</sup> Ibid [PEN.012.1551] at 1567

<sup>33</sup> Dr Foster – Day 41, pages 102–103

<sup>34</sup> Note that HIV had yet to become a concern for fractionators at this point in time.

<sup>35</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1567; Dr Foster – Day 41, pages 72–75; See Kasper et al, 'Recent evolution of clotting factor concentrates for hemophilia A and B', *Transfusion*, 1993; 33:422–434 [SGH.002.1947] at 1950

- It was thought by some that there were two variants of NANB Hepatitis virus whose properties differed in important ways.
- It was thought that heat-treating Factor VIII could potentially alter its structure and lead to the formation of so-called 'neo-antigens' in patients' immune systems – that is the creation of antibodies to Factor VIII which would prevent further infusions of Factor VIII from being effective.<sup>36</sup>
- There was a concern that heat-treating Factor IX could lead to increased thrombotic reactions in patients – that is the formation of blood clots.<sup>37</sup>
- It was obvious that effective pasteurisation would be at a cost in Factor VIII yield, the amount of Factor VIII activity recovered from a given quantity of frozen plasma.<sup>38</sup> That was an obstacle for a public service struggling to reach or to maintain self-sufficiency.
- There was a need to balance possible decreases in yield against an increasing demand for factor concentrates.<sup>39</sup>

**23.21** For Dr Smith, these concerns had a real and practical significance. In April 1981, he was responsible for designing the coagulation section of the, then proposed, new BPL fractionation facility for England and Wales.<sup>40</sup> In his field, it was beginning to be realised generally that NANB Hepatitis was a more serious problem for recipients of plasma products than hitherto appreciated. He was of the view that this was undermining broader perceptions, among patients and expert groups, of the safety of large-pool fractionation. There was no solution to the risk of transmission for large-scale production. The production of small-pool Factor VIII and Factor IX concentrates was uneconomical. Nevertheless, he planned for sufficient small-pool concentrates to be produced either aseptically or under tight environmental control, to protect infants and other previously untreated patients from NANB Hepatitis, until a solution was 'arrived at by someone'. He was buying time 'until the cavalry appeared'.

**23.22** The scheme would have reduced the statistical risk for the most vulnerable.<sup>41</sup> Dr Smith said:

[B]y that time I was the person in the dock – or the driving seat, depending how you care to put it – who was responsible for having contingency planning and it would seem to me in 1981 that we might not be arriving at a solution to non-A non-B Hepatitis by the time we wished to move into the new building.<sup>42</sup>

With all his experience and expertise, he did not foresee a solution to the problem of virus inactivation at that time.

**23.23** Although research was undertaken from the mid-1940s until around the 1970s with the aim of inactivating the agent responsible for the transmission of serum (blood-transmitted) hepatitis, the evidence available to the Inquiry, and noted briefly at the end of

<sup>36</sup> Professor van Aken – Day 47, pages 12–15. These antibodies are otherwise referred to as 'inhibitors'.

<sup>41</sup> Dr Smith – Day 59, page 67

<sup>42</sup> Dr Smith – Day 59, pages 63–64

Chapter 20, *Haemophilia Therapy – The Period up to the Early 1980s*, indicates that none of the methods used were effective in eliminating infectivity without causing unacceptable damage to the product in question. The methods included: (i) the application of heat; (ii) the addition of chemicals; and (iii) the application of different forms of radiation.<sup>43</sup> Research was also undertaken in the 1970s into the physical filtering of viruses in the production process. None of these methods was used in the routine manufacture of human plasma products.<sup>44</sup> There had been a measure of success in eliminating the risk of transmission of Hepatitis B, until the mid-1970s thought to be responsible for most blood-borne hepatitis, by effective screening of donors, not by treating blood and blood products.

### **Commercial research**

**23.24** By the end of the 1970s/early 1980s, however, potentially promising research was being undertaken by commercial companies. As regards Factor VIII, the research was primarily focused on either heating the product in solution (pasteurisation) or dry-heating of the product as a freeze-dried powder. Pasteurisation had the perceived advantage that – being water-based – it was likely to be more effective at destroying viruses, but equally it was more likely to damage blood proteins. As outlined by Dr Smith during his oral evidence:

Virtually all biological, chemical reactions operate with the assistance of – through the medium of water. The water which you would think is simply a background material, holding the things together, is in fact a player in virtually all the reactions. Turning to the reactions which tend to inactivate proteins or denature them, these are heavily dependent on how much water is there. In a dry-heated product you are down to less than 1 per cent of water. In a pasteurisation situation it is all water essentially. Therefore, the ... potential damage to your protein is much more severe in the aqueous pasteurisation context than it is in the dry heating context. Equally, of course, the damage you are doing to viruses, you hope, is much more severe.<sup>45</sup>

**23.25** The use of stabilisers to protect the protein was essential. However, the choice of stabiliser was crucial since:

[I]n pasteurisation, in trying to protect your protein from what you know will be a damaging experience, you add too much of the wrong kind of stabilisers, you always fear that you have also, in doing so, failed to inactivate so much of the virus; you have protected the virus as well as the protein.<sup>46</sup>

**23.26** It was also, to a large degree, a matter of trial and error:

It's largely empirical. There are certain classes of substance which have been used more than others: salts, amino acids, sugars, at very high concentration ... you would start with certain things, and only then, having exhausted those and all the conditions under which you might apply them, you would start to turn to rather more exotic protectants.<sup>47</sup>

<sup>43</sup> Dr Foster – Day 41, pages 65–66; For more details see SNBTS Briefing Paper on the Development of Heat Treatment of Coagulation Factors [PEN.013.1309] at 1321

<sup>44</sup> Dr Foster – Day 41, page 66; SNBTS Briefing Paper on the Development of Heat Treatment of Coagulation Factors [PEN.013.1309] at 1322

<sup>45</sup> Dr Smith – Day 59, pages 31–32

<sup>46</sup> Dr Smith – Day 59, page 32

<sup>47</sup> Dr Smith – Day 59, page 32

**23.27** In contrast to pasteurisation, where a product had been freeze-dried in powder form, the lack of water and the presence of a vacuum would, in principle, make it more difficult to direct heat to the core of the powder.<sup>48</sup>

**23.28** Commercial research led to the release of a wide range of commercial heat-treated Factor VIII and Factor IX products in the USA (from 1983). Appendix 1 to this chapter tabulates the products together with the dates of licensing in the USA.<sup>49</sup> Commercial heat-treated products were not licensed by the UK Medicines Control Agency for release in the UK until February 1985.<sup>50</sup> Some products were not available in the UK. Behring's product, Haemate P, was available in small quantities from 1980 in Germany and some other places.<sup>51</sup> It was not licensed in the UK and was not available here at any time.<sup>52</sup>

**23.29** These products, which were difficult to develop, were not widely used.<sup>53</sup> Each additional step in the manufacturing process carried a yield penalty. With the exception of pasteurisation, they were not effective in destroying the agent(s) responsible for NANB Hepatitis. Initial chimpanzee studies of Hemofil T suggested that it was effective in preventing transmission of NANB Hepatitis but not Hepatitis B. In human recipients, the opposite outcome was reported.<sup>54</sup> The animal model was not reliable.

**23.30** As the tables in Appendix 1 to this chapter show, licences for heat-treated factor concentrates began to be issued in the USA in March 1983. Some at least of the procedures that were developed were protected by patents, and, in the nature of things, prior publication of the inventive steps in the processes developed was unlikely, and, to the extent that it happened at all, even more unlikely to be comprehensive. As far as the SNBTS is concerned, its first heat-treated Factor VIII product (heated to 68°C for two hours) was released in December 1984.<sup>55</sup>

## Research at the Protein Fractionation Centre: progress in the early 1980s

### 1980

**23.31** From the perspective of the PFC, there appear to have been few notable developments in the field of viral inactivation of factor concentrates early in 1980. Dr Brian McClelland attended a meeting of the Medical Research Council Working Party on Post-Transfusion Hepatitis on 14 February 1980.<sup>56</sup> However, as regards hepatitis the discussion recorded was limited to: (i) work by the German company Biotest (not Bayer as noted in the minutes of this meeting<sup>57</sup>) into using  $\beta$ -propiolactone together with ultraviolet radiation to inactivate hepatitis (this work did not ultimately lead to a successful product) and (ii) the polyelectrolyte process developed by Dr Johnson mentioned at the end of Chapter 20, *Haemophilia Therapy – The Period up to the Early 1980s*.<sup>58</sup>

<sup>48</sup> Dr Smith – Day 59, pages 30–31

<sup>58</sup> Dr Foster – Day 41, pages 109–110; Minutes of MRC Working Party on Post-Transfusion Hepatitis, 14 February 1980, paragraphs 3.3 and 3.4 [DHF.002.4845] at 4847; Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1446

**23.32** Bayer (Cutter Laboratories) filed an original application for protection of a pasteurisation process on 5 March 1980.<sup>59</sup>

**23.33** Towards the end of 1980, however, news had started to filter through to the PFC of the apparent breakthrough by Behringwerke AG ('Behring') in the pasteurisation of Factor VIII already noted. The news was broken to the fractionation community during the First International Haemophilia Conference in Bonn, Germany between 3 and 7 October 1980<sup>60</sup> which was attended by Professor Cash. On his return to the UK, Professor Cash told Dr Foster that the company had claimed that it had succeeded in pasteurising Factor VIII.<sup>61</sup> Subsequently, on 27 October 1980, he wrote a letter to Mr John Watt in which he said:

During the meeting in Bonn I learnt, for the first time, that Behringwerke are getting rather excited – following chimpanzee studies – that their preparations of factor VIII, made from HBsAg positive plasma (starting at 90 ng/ml), appear to be safe. The reason given is that they are heat treating the product for 10 hours at 60°C in the presence of glycine and sucrose. Apparently the glycine and sucrose protect the VIII from denaturation. Sounds unbelievable: thought you might be interested.<sup>62</sup>

**23.34** Dr Foster said in his witness statement that he was 'quite shocked' when he heard of this claim. The notion that Factor VIII might be able to be heat-treated under conditions that would destroy hepatitis viruses was inconceivable to him.<sup>63</sup> In his oral evidence, he said that on hearing the news he was, 'completely gobsmacked'.<sup>64</sup> Dr Robert Perry was not directly involved, but it was clear from his evidence that the claims were widely discussed within the SNBTS and the PFC and that there was a sense of incredulity that the process could take place.<sup>65</sup> Dr Foster was asked whether, intuitively, treating Factor VIII at 60°C would not work. He said:

I can't admit that I ever considered that. It was just so – literally inconceivable. I didn't sit down and say, 'Would this work or would it not work?' it was something I didn't even consider, it was inconceivable.<sup>66</sup>

**23.35** Dr Frank Boulton did not believe that it could possibly be true and expected that it would be found out to have been a mistake.<sup>67</sup> When Dr Foster and others reported some of their own research in this area later,<sup>68</sup> Dr Garrott Allen wrote, expressing surprise, commenting on his own failure, and asking for details.<sup>69</sup> The value of the Behring discoveries was that they demonstrated that in principle Factor VIII could be pasteurised, if suitably protected, in a high purity product. The PFC could not copy the Behring patented process: it would have to produce its own.<sup>70</sup>

<sup>59</sup> Fernandes P and Lundblad JL 1982. *Pasteurized therapeutically active protein compositions*. US Patent 4,440,679, filed 20 December 1982 and issued 3 April 1984 [SNB.004.5922]. Continuation of application number 127,351, filed 5 March 1980.

<sup>70</sup> Dr Pepper's statement on viral inactivation to 1985 [PEN.013.1391] at 1394

**23.36** The reasons for Dr Foster's disbelief mirror the general points outlined above by Dr Smith.<sup>71</sup> According to Dr Foster, the established view at the start of the 1980s remained that plasma proteins would be damaged by the level of heat needed to kill viruses. That also accorded with Dr Foster's first-hand experience of working with Factor VIII, as noted at the end of Chapter 20, *Haemophilia Therapy – The Period up to the Early 1980s*, at paragraph 20.75. He had found that Factor VIII from human plasma was considerably more sensitive and more difficult to work with than any of the other proteins that he had encountered.<sup>72</sup>

**23.37** Professor Cash appears to have been the first SNBTS official to become aware of Behring's progress on the heat treatment of Factor VIII.<sup>73</sup> At the end of 1980, however, the specific details of the process were not available to the PFC. After the meeting in Bonn, Behring disclosed certain details in an internal Behring journal called *Die gelben Hefte* (the Golden Notebook).<sup>74</sup> The journal would not have been readily available in the UK. Dr Foster first received a copy of this article when attending a conference in Budapest in 1982.<sup>75</sup> Professor Pier Mannucci saw a copy of the article in 1980. He wrote:

I, like other clinicians, was unimpressed with the claim because clinical evidence was meager and the design of the study retrospective and poor.<sup>76</sup>

Behring's product, Haemate P, was first licensed in Germany in 1981, where it was claimed to be the first effectively virus-inactivated Factor VIII product. The claims advanced for the Behring process are set out in the Preliminary Report at paragraphs 11.45–11.47.

**23.38** In summary, by the end of 1980 Behring had carried out research into the pasteurisation of Factor VIII which appeared to have promise, but an unacceptably low yield. A yield of about 8% of the initial plasma was confirmed in 1981.<sup>77</sup> The details of this research do not appear to have been made public at this time. Behring's approach to publication was described by Dr Smith as a 'teasing process'. The manufacturer would not disclose enough to invalidate his patent, but would hint at developments to come.<sup>78</sup> However, the PFC was aware of the general development.

## 1981

**23.39** Limited information about the procedures used by Behring were published in 1981 in the journal *Haemostasis*.<sup>79</sup> Details of the procedures were ultimately published in April 1981 in an article in the German journal *Arzneimittel Forschung/Drug Research*.<sup>80</sup> Dr Foster obtained a reprint of this document in May 1981 from the Behring trade stand at a symposium in Cambridge on 'Advances in Blood Transfusion' which was organised for Transfusion Directors by Travenol Ltd and which was by invitation only.<sup>81</sup> The article was

in German and was translated into English by Dr Werner Zolg, a German post-doctoral researcher at Edinburgh University who was at that time involved in a collaboration on a different project with Dr Alex MacLeod – a research scientist at the PFC.<sup>82</sup>

**23.40** Shortly afterwards, Dr Foster became ill and did not return to work until mid-October 1981. During this period, Dr MacLeod obtained the translation from Dr Zolg and, on his own initiative, on 2 September 1981 started a set of experiments aimed at reproducing Behring's findings.<sup>83</sup> The view in the PFC, differing from Professor Mannucci, was that Behring was a well-respected company, and, if they said a process was feasible, it was worth pursuing even if one remained sceptical about the yield and about proof that the viruses were sufficiently inactivated.<sup>84</sup> According to Dr Foster:

The early research of Dr MacLeod was essentially exploratory and aimed to confirm the findings of Behring and to establish whether or not the approach taken by Behring might be feasible and suitable for the PFC to pursue.<sup>85</sup>

A particular focus for this research was on identifying stabilisers and conditions which might allow pasteurisation to be developed without breaching Behring's patent.<sup>86</sup>

**23.41** Thus, by the end of 1981, as a response to Behring's work, research into the pasteurisation of coagulation factors had begun at the PFC. However, the published yield of eight per cent was a serious draw-back from the point of view of the PFC. In Dr Perry's recollection, the low yield meant that the process had no practical applicability in Scotland (where all coagulation factor production, of necessity, came from the limited Scottish donor population).<sup>87</sup>

**23.42** On 17 December 1981, Professor Cash wrote to Mr Watt, Dr Perry, Dr Foster, Dr Prowse, Dr Boulton, Dr Pepper and Dr G S Gabra intimating the setting up of the SNBTS Factor VIII Concentrate Study Group (Factor VIII Study Group) and inviting them to be members. The group was to have as its remit the exploration of:

[N]ew developments in the widest possible sense with regard to the production of factor VIII concentrates and thereby create the opportunity for cross fertilisation and for co-ordinated research within the SNBTS.<sup>88</sup>

**23.43** This group later formed an important forum for the discussion of matters relating to viral inactivation.

## 1982

### The PFC continues its research into heat treatment options and Behring's pasteurisation process

**23.44** The first meeting of the Factor VIII Study Group took place on 28 January 1982. The minutes of the meeting indicate that Dr Christopher Prowse mentioned pasteurisation in the context of inactivating viruses.<sup>89</sup> He said that the HQ laboratory unit of the SNBTS was

<sup>88</sup> Professor Cash's letter of 17 December 1981 [SNB.001.3587]

<sup>89</sup> Minutes of the Factor VIII Study Group, 28 January 1982 [SNF.001.3813] at 3813

carrying out experiments using gamma-irradiation.<sup>90</sup> Viral inactivation was not highlighted in the list of current research priorities, however, and Dr MacLeod's research into Behring's process was not referred to.<sup>91</sup> During the meeting, Professor Cash recommended the setting up of a separate sub-committee with a view to improving 'the safety of the product, eg by irradiation to remove viral infectivity'.<sup>92</sup>

**23.45** This sub-committee became known as the Safety Action Group and held its first meeting on 9–10 February 1982.<sup>93</sup> A discussion document set out what was known and what might be attempted. The meeting summarised the existing knowledge within the SNBTS as regards methods of viral inactivation as well as outlining proposals for action and resources required. Gamma-irradiation was discussed as was the possible use of a combination of b-propiolactone and ultraviolet irradiation.<sup>94</sup> Behring's pasteurisation method was also mentioned, and it was noted that:

An alternative to g-irradiation is heating (pasteurisation). This has been attempted by Behringwerke who now market 'Faktor VIII HS' in which HS implies, "safe from hepatitis". Unfortunately only one paper has been published (in German) and no details are given of solution compositions or yields. However, estimates by P.F.C. indicate 8% yield which is rather low.<sup>95</sup>

**23.46** Although Behring's work was discussed, once again no mention was made during this meeting of the fact that the PFC had already begun investigations, under Dr MacLeod, into whether Behring's findings could be confirmed. Dr MacLeod's work was not included in the proposals for action. The Inquiry has asked whether the lack of a mention of Dr MacLeod's research in this meeting and the earlier meeting of the Factor VIII Study Group could be interpreted as meaning that this research was not a priority for the PFC at this time, or that Professor Cash was not aware of the research.<sup>96</sup> Dr Foster said that, in his view, this was not the case. He explained that:

The first meeting of the Factor VIII Study Group was held on the 28th January 1982, some two weeks before Dr MacLeod had completed his preliminary evaluation. I am sure that Dr Cash was aware of our work on pasteurisation when he arranged the first meeting of the Factor VIII Study Group but, as the exploratory experiments of Dr MacLeod were incomplete, it is understandable that he did not include this topic in the agenda of the first meeting of the Group.

Similarly the meeting of the Safety Action Group of 9–10 February 1982 ... preceded the report of Dr MacLeod.<sup>97</sup>

**23.47** Dr Perry's evidence to the Inquiry also explains that any perceived lack of focus on pasteurisation at this time should be seen in the context of the more general goals of the Factor VIII Study Group:

The Factor VIII study group was an important development in SNBTS and was established to coordinate all available resources in SNBTS to meet the

<sup>90</sup> Minutes of the Factor VIII Study Group, 28 January 1982 [SNF.001.3813] at 3817–18; Dr Pepper's statement on viral inactivation to 1985 [PEN.013.1391] at 1393

<sup>91</sup> As already noted, Dr MacLeod did not report his work until 10 February 1982 [PEN.012.1489]

<sup>96</sup> Inquiry's schedule of questions on viral inactivation to 1985 [PEN.012.1531] at 1532

<sup>97</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1452

challenges of self-sufficiency and to establish this as a national priority. I attended this meeting together with Dr Foster and Mr Watt from PFC. At this time the PFC work on virus inactivation was only at a preliminary stage without any clear reportable outcomes. My recollection from the meeting is that safety issues were discussed in general leading to agreement to establish a safety sub group. Whilst this is not recorded in the report of the meeting this would not necessarily be unusual for such internal reports. The importance of product safety was certainly recognised in these discussions but so was the recognition that any method likely to improve safety would reduce product yield. Thus consideration of FVIII processing yield and FVIII content of plasma were considered essential prerequisites to progress on product safety if the goal of self sufficiency was to be achieved and maintained.<sup>98</sup>

**23.48** So, even at this early stage, there appears to have been a recognition that improvements in safety had to be balanced against the general goal of self-sufficiency and the need to improve yield to offset any losses caused by viral inactivation.<sup>99</sup>

**23.49** Dr MacLeod's initial findings on his preliminary studies, following the methodology in the Drug Research paper, were summarised shortly thereafter in a PFC R&D report of 10 February entitled 'Preliminary studies on the heat treatment of PFC FVIII concentrate'.<sup>100</sup> The document reported briefly on the initial PFC experiments with heating Factor VIII using glycine and sucrose as stabilisers and concluded that further purification of the PFC's Factor VIII concentrate seemed necessary in order to be able to pasteurise the product.

**23.50** Dr Foster's view was that:

The immediate challenge was therefore two-fold. To discover a means of increasing purity to allow the pasteurisation process to be applied, whilst at the same time substantially increasing the yield ... to enable the SNBTS to provide the quantity of factor VIII concentrate required.<sup>101</sup>

**23.51** This became a major consideration of the Safety Action Group at the PFC.<sup>102</sup> An account of their discussions between February and July 1982 is given in the Preliminary Report at paragraphs 11.57–11.68. In the background was a commitment to self-sufficiency that implied that any strategy that led to failure to meet the escalating demand for product for all of Scotland's patients was not viable.<sup>103</sup> Self-sufficiency was, in Dr Perry's words, 'the only game in town'. He said:

[T]hat culture and that ethos really pervaded everything we did. And for very good reason. It was clearly understood why we had that particular position .... [E]very bottle of product or every vial of product, every dose of product that we could make from Scottish donors avoided the need to import material from what we perceived and believed were less safe parts of the world, and particularly the American commercial material. So it wasn't just a sort of random process of pride or national pride that we would be self-sufficient, there was a very good reason underlying it. And certainly I internalised that at a very early stage. Every morning I woke up, basically the reason for going to work was

<sup>103</sup> Dr Perry – Day 45, pages 18–19

to make sure that we could avoid having to import product from areas that were believed to be less safe than Scottish donors. So where it actually came from, I think certainly pre-dated me. I think certainly Professor Cash – and this is from me reading the sort of historical archives. There were discussions when he took over as national medical director that, I think, one of the clear discussions he had before taking up the post was, you know: is part of the job here to establish self-sufficiency? And I think the answer to that was yes .... [L]eading from that process were discussions between Professor Cash and George MacDonald in the West of Scotland and various other haematologists and haemophilia directors, where they sought to establish what that meant, and the figure that I always had in mind was 2.75. That was the magic figure.<sup>104</sup>

**23.52** There were no policy statements or documents to that effect. But:

It was in the fabric of the building, it was in the fabric of everything that was discussed, that, you know, the PFC was established at great expense to the taxpayer and its job was to meet the needs for Scottish patients. So, you know, I guess I'm just a single point in this process, but for me it became very clear very early on what we were there for and that included – and in a sense, failing to supply was – it sounds a bit romantic but failure to supply was not an option .... [I] think it would have been seen as an admission of failure of delivery against our mission and purpose. Certainly that's how I perceived it anyway.<sup>105</sup>

Dr Perry did not think that the Common Services Agency (CSA) and its committees lived and breathed self-sufficiency to the extent the SNBTS did.<sup>106</sup>

**23.53** Further meetings of the Factor VIII Study Group and the Safety Action Group followed throughout spring/summer 1982. The meeting of the Safety Action Group of 30 March 1982 proposed that work should be carried out into filtration, that Dr MacLeod's research into Behring's pasteurisation process should be pursued and that Dr Duncan Pepper should investigate aspects of irradiation. Practical aspects of these strands of proposed research (laboratory accommodation, access to infected material, which animals could be used to test for infectivity – so-called 'animal models' – and funding) were also discussed.<sup>107</sup> The issue of possible animal models was also discussed during the Factor VIII Study Group meeting on 3 June 1982.<sup>108</sup> It was also dealt with in more detail during the meeting of the Safety Action Group on 23 June 1982, which investigated the possibility of infecting Tamarin monkeys with known NANB Hepatitis infected material and carrying out titrations to measure the effectiveness of various inactivation processes: heat, gamma-irradiation, adsorption, purification and the use of detergent.<sup>109</sup> Therefore, by the middle of 1982, the PFC was continuing its examination of the options for viral inactivation. However, no one option had yet been chosen.

**23.54** Dr Bruce Cuthbertson characterised much of the work of the Safety Action Group as 'blue sky thinking'.<sup>110</sup> However, the discussion focused on what were seen at the time as real possibilities. For example the animal studies were seen as a serious prospect in

<sup>104</sup> Dr Perry – Day 45, page 32–33

<sup>110</sup> Dr Cuthbertson – Day 46, page 30

May 1982. SNBTS scientists in this respect reflected the ambition of the organisation, notwithstanding that it was a small operation in a small country.<sup>111</sup> Dr Smith had a more positive view of the work of the group:

I would like to reaffirm just how wide-ranging SNBTS's experiments were. In fact, on theoretical grounds, it would seem to most people far more likely that radiation would distinguish between proteins and an assembled entity like a virus. This simply did not happen. Nature did not cooperate in this case but it does exemplify the lengths that this study group went to in exploring every avenue.<sup>112</sup>

### **Protein Fractionation Centre obtains further information on current viral inactivation research at an International Congress in Budapest**

**23.55** Dr Foster attended the International Society of Haematology/International Society of Blood Transfusion Congress in Budapest between 2–5 August 1982 and produced a detailed report which, among other things, summarised information about recent viral inactivation research publicised during the conference.<sup>113</sup>

**23.56** Behringwerke did not present at the conference. However, it did provide copies of certain documents as part of a trade stand which was held in conjunction with the Congress.<sup>114</sup> These included:

- A Behring paper on Factor VIII published on 16 July 1982 which emphasised the variation in purity and Factor VIII activity of a range of commercial products as compared to Behring's highly purified product.<sup>115</sup>
- A typewritten version of the paper, referred to at paragraph 23.37 above, on the Behring pasteurisation process which had been published in *Die gelben Hefte* in 1980.<sup>116</sup>

**23.57** The introduction to the typewritten paper on the Behring pasteurisation process stated that:

Until recently it has been impossible to eliminate the danger of hepatitis from certain plasma products, in particular clotting factor concentrates. When using factor VIII concentrate for haemophilia it was therefore necessary to weigh the benefits against the hazards. Now, however, thanks to a new manufacturing process, a safe Factor VIII concentrate is available. Experimental and clinical trials have confirmed its freedom from hepatitis risk.

**23.58** It also emphasised the medical need for a safer product, noting that:

Haemophiliacs, because they require lifelong replacement therapy with coagulation factor concentrates, are exposed to considerable risks of hepatitis. Twenty years ago, before the introduction of effective replacement therapy, haemorrhage was the major hazard, but today its place has been taken by chronic liver disease.

---

<sup>111</sup> Dr Cuthbertson – Day 46, pages 34–36

<sup>112</sup> Dr Smith – Day 59, page 35

<sup>113</sup> Dr Foster's report on the conference [SNB.010.4452]

<sup>114</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1453

<sup>115</sup> Kröniger et al, 'Factor VIII concentrates: problems and protein-chemical characterization', *Die Medizinische Welt*, 1982; 33:1027–1033 [SNF.001.0921]. Note that the paper made no explicit claims that the Behring product was hepatitis safe.

<sup>116</sup> Heimburger et al, 'Factor VIII concentrate – now free from hepatitis risk; progress in the treatment of haemophilia', undated typescript [SNF.001.0929]

**23.59** The paper included a discussion of the various perceived options for reducing the risk of hepatitis transmission, indicating that: (i) vaccines and immunoglobulins were not available for NANB Hepatitis; (ii) single donor cryoprecipitate derived from medically supervised regular donors would have solved the problem only for a very small number of patients; and (iii) the combination of  $\beta$ -propiolactone and ultraviolet irradiation, which had been used in Factor IX, was not applicable to Factor VIII. Consequently:

In view of these facts we endeavoured to work out a method for producing hepatitis-free Factor VIII concentrate. We chose heat sterilisation, because it had been used for albumin for many years and was of established value. The removal of hepatitis risk by the albumin production process is based essentially on three stages: 1. Screening of all donor plasmas by a third generation test and rejection of HBsAg-positive donations. 2. Elimination of hepatitis virus (BV) during the fractionation process. 3. Inactivation of any residual virus particles by heating the final product to 60° for 10 hours. The Factor VIII molecule is highly susceptible to elevated temperatures and the heating process was made feasible only by addition of stabilizers which protect the molecule from thermal inactivation.<sup>117</sup>

**23.60** The paper outlined experiments which had been carried out to establish whether the viral inactivation protocol had been effective, concluding that:

In the light of the experimental and clinical results it may be said that the possibility of transmission of hepatitis B by Factor VIII HS can be ruled out. Furthermore, non-A/non-B hepatitis has so far not been observed and the characteristic ... signs have not been seen. However, long-term observation is being continued so that a definitive statement can be made.<sup>118</sup>

**23.61** Thus, although there was no final proof at this stage that the Behring product was free from NANB Hepatitis, the company claimed to have had encouraging indications of possible success.<sup>119</sup>

**23.62** In addition to receiving more information on the Behring process in Budapest, Dr Foster learned that Biotest were making progress with  $\beta$ -propiolactone and ultraviolet treatment; and that an independent research company, Rubenstein and Rubenstein, were pursuing dry heat treatment. He also became aware of Hyland/Baxter's announcement that it had developed a heat-treated product. In his report, Dr Foster indicated that Hyland's method 'was said to involve pasteurisation'.<sup>120</sup> However in his evidence to the Inquiry, Dr Foster indicated that 'at the time I didn't know what it was and it was only later that we discovered it was a dry heat process'.<sup>121</sup> More specifically, in his written evidence Dr Foster stated that:

The method of heat treatment was not disclosed at the Congress. Some months later, Dr Chris Prowse of the SNBTS learned from Dr Henry Kingdon, the Medical Director of Hyland/Baxter, that the procedure involved dry-heat treatment at 60°C. What had been done to enable the Hyland/Baxter Factor VIII concentrate (Hemofil) to withstand this degree of heat treatment was not disclosed and, to the best of my knowledge, has never been disclosed.<sup>122</sup>

<sup>117</sup> Ibid [SNF.001.0929] at 0932

<sup>118</sup> Ibid [SNF.001.0929] at 0941

<sup>119</sup> See also Preliminary Report, paragraphs 11.74–11.78

<sup>120</sup> Dr Foster's report on the Budapest conference [SNB.010.4452] at 4456

<sup>121</sup> Dr Foster – Day 41, page 129

<sup>122</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1454

**23.63** At the time Dr Foster regarded Hyland's product as having potential, noting in his report that:

The Hyland product is perhaps the most interesting. If the yield indicated (200 iu/l) is confirmed this is probably higher than the present method of manufacture for Hemofil and therefore represents a definite break-through in FVIII stabilisation. Will this ever be published?<sup>123</sup>

**23.64** However, when asked at the Inquiry how he would characterise the information from Hyland, Dr Foster remarked that it should be viewed as 'tantalsing' and that 'it was a heat-treated product that gave no indication as to whether it might deal with viruses or not .... So the questions were still waiting to be answered'.<sup>124</sup> Dr Smith commented in his written statement that the paper would have served to increase interest in pasteurisation, and perhaps increase its priority.<sup>125</sup> As outlined in more detail below, the product was ultimately found to transmit NANB Hepatitis.<sup>126</sup>

**23.65** Dr Foster described the work carried out by Rubenstein,<sup>127</sup> using labile factors in their freeze-dried state, as 'very interesting'.<sup>128</sup> But he thought that freeze-drying was also likely to protect the virus and infectivity data were essential. In his written evidence, Dr Foster indicated that it was at this conference that he first became aware of the possibility of heat-treating freeze-dried factor concentrates, commenting that:

It was also at the 1982 ISBT Congress that I first learned of the concept of applying heat treatment to coagulation factor concentrates in the freeze dried state (ie. dry-heat treatment). These were listed in the programme as poster presentations at which the authors would be present to answer questions on their work. In the event, the posters were not displayed nor were the authors present at the poster session to answer questions.<sup>129</sup>

### *Pasteurisation selected as preferred viral inactivation option*

**23.66** The Factor VIII Study Group met again on 14 October 1982 and discussed the activities of the Safety Action Group. The minutes of the Safety Action Group record that:

Heat Treatment was now the first option of the group in view of developments which had occurred since the last meeting. Dr Alex McLeod [sic] (PFC) would continue studies of heat process using high purity product. Edinburgh BTS to assist if necessary.<sup>130</sup>

**23.67** A number of witnesses were asked the reason for the decision of the Factor VIII Study Group to focus on the heat treatment of a high-purity product.<sup>131</sup> In his written evidence Dr Perry stated that:

By October 1982 SNBTS had eliminated irradiation and virus removal as options for increasing FVIII safety. Irradiation in particular led to complete destruction of the product at doses necessary to achieve a sufficient degree of virus inactivation.

<sup>128</sup> Dr Foster's report on the Budapest conference [SNB.010.4452] at 4459

<sup>129</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1453–54

<sup>130</sup> Minutes of Factor VIII Study Group meeting, 14 October 1982 [SNB.001.3932] at 3932

<sup>131</sup> Inquiry's schedule of questions on viral inactivation to 1985 [PEN.012.1531] at 1532

Therefore heat (pasteurisation) was selected as the preferred option not only because of the reported success of Behring but also because other lines of research had proven unsuccessful.<sup>132</sup>

**23.68** Dr Foster explained in his witness statement that the reasons for prioritising heat treatment were as follows:

- a). Although I was not a member of the Safety Action Group, I believe that there were three principal reasons why pasteurisation was, by 14 October 1982, *'the first option of the group'*.
- b). The first reason concerned the promising results that had been presented by Behring at the ISBT Congress in August 1982.
- c). The second reason was the discovery of a suitable means of reducing the fibrinogen content of Factor VIII. This discovery had been made at PFC in conjunction with Dr Milan Bier of the University of Arizona and involved the addition of zinc,<sup>133</sup> which preferentially caused fibrinogen to precipitate, whilst leaving factor VIII in solution (Bier M & Foster PR. USA Patent 1983, No. 4,406,886). This discovery enabled the purity of factor VIII to be increased prior to pasteurisation with little loss of yield and addressed the need for an increase in purity which Dr MacLeod had identified in his report of 10th February 1982. This was the *'high purity product'* that was noted in the minute of the meeting of the Factor VIII Study Group of 14th October 1982.
- d). The third reason was the promising results that Dr MacLeod had obtained using sorbitol instead of sucrose to stabilise factor VIII during pasteurisation [Preliminary Report para 11.86], which reduced the loss of factor VIII during the heat treatment process.<sup>134</sup>

**23.69** Witnesses were also asked whether the decision to focus on heat treatment could have been due to the PFC's existing knowledge of and experience in the pasteurisation of albumin.<sup>135</sup> In his evidence to the Inquiry Dr Foster explained that, although the heat treatment of albumin *'represented a bench-mark against which new procedures could be compared'*,<sup>136</sup> it could not simply be copied for other coagulation factors since *'the chemical stabilisers were not able to stabilise other plasma proteins, including the coagulation factors'*.<sup>137</sup>

**23.70** Dr Perry, in his written evidence, commented that it was not correct to assume that the choice of pasteurisation by either Behring or the SNBTS was based simply on prior experience with equipment and facilities for albumin production.<sup>138</sup> He, too, emphasised that albumin was a relatively stable protein in the liquid state. Pasteurisation of albumin involved the addition of non-toxic stabilisers which did not require to be removed following pasteurisation. In contrast coagulation factor proteins were known to be unstable in the

<sup>132</sup> Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1763. See also Dr Cuthbertson's statement [PEN.013.0025] at 0029 for similar reasoning.

<sup>137</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1455

<sup>138</sup> Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1763–64

liquid state and were rapidly destroyed at elevated temperatures. There were no known stabilisers which could prevent destruction of the coagulation proteins present in the concentrates when exposed to elevated temperatures. In developing virus-safe coagulation factor products with acceptable yield, pharmaceutically suitable stabilisers capable of protecting unstable coagulation factor proteins from the effect of heat, and reducing the concentration of other heat-labile proteins in the product, were required, as were processing methods (including potentially the removal of stabilisers after pasteurisation). These were complex scientific problems. Dr Perry said:

Following the discovery by Behring of suitable stabilisers, SNBTS embarked on a programme to develop a similar process which was capable of delivering an acceptable product yield and which did not infringe the Behring patents.

SNBTS (and probably Behring also) selected pasteurisation at 60 degrees for 10 hours because such established processes were already known to produce safe albumin products and it was thought likely that such processes would similarly deliver safe coagulation factors.

The availability or otherwise of equipment to carry out the specific pasteurisation step in the overall process was a relatively minor consideration.<sup>139</sup>

As noted above at paragraph 23.67, Dr Perry also said that SNBTS research into the use of gamma radiation and methods of physically removing virus from Factor VIII had proven unsuccessful.

**23.71** Dr Cuthbertson's written evidence gave a slightly more positive view of the attractions of the existing albumin process of heating for 10 hours at 60°C noting that 'it was not surprising that Behringwerke chose this time and temperature combination for their process and it had clear attractions for the PFC in that pasteurisation equipment was already available in the PFC facility'.<sup>140</sup> However, Dr Cuthbertson also indicated that 'the outstanding safety record which applied to albumin could not be directly extrapolated'<sup>141</sup> to Factor VIII and that the key issue was finding stabilisers which would preferentially protect Factor VIII (but not viruses) from heat.<sup>142</sup>

### **Cooperation between Protein Fractionation Centre and Blood Products Laboratory**

**23.72** Shortly after the Factor VIII Study Group meeting of 14 October 1982, correspondence followed between the PFC and the BPL regarding heat treatment. Dr Foster wrote to Dr Smith of the BPL on 19 October 1982:

On the FVIII front we are still grinding away at the yield problem and have started to look again at the high purity situation. We are currently pursuing precipitation by metal-ions, which is something we stumbled on with Milan Bier a few months ago. The early results are interesting but its going to be stuck on the lab bench for a long time yet. Everyone is getting very hot about pasteurisation, especially since Budapest. The little work that we have done

<sup>139</sup> Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1764

<sup>140</sup> Dr Cuthbertson's statement on viral inactivation to 1985 [PEN.013.0025] at 0029

<sup>141</sup> Ibid [PEN.013.0025] at 0029

<sup>142</sup> Dr Cuthbertson – Day 46, page 43; see also Dr Smith's written statement [PEN.012.1551] at 1568 'JKS Note 2' where he emphasises the difficulty of removing the stabilisers from the resultant solution.

suggests that higher purity material is needed and so far FVIII (using Duncan's CAG assay) has always gone into the solids phase!<sup>143</sup>

Dr Smith replied on 3 November 1982 indicating that:

We are doing a little on heating factor VIII, but only for the moment on the gentle conditions for fibrinogen removal. I cannot see us doing the infinitely factorial experiments and infusions required to 'solve' factor VIII and would appreciate any small signal of success from your efforts.<sup>144</sup>

**23.73** In his written statement Dr Smith outlined the background to this comment noting that:

Brief heating at temperatures around 60°C, without stabilisers, was being considered as a means of precipitating fibrinogen as a solid while leaving most F.VIII in solution – by no means an original idea, but we were ready to try almost anything short of voodoo. There was no intention to inactivate NANBH. The letter goes on to say that BPL was in no shape to start serious work on pasteurisation (anticipating a very long haul) and that I would be very pleased if PFC's work might offer some encouragement.<sup>145</sup>

**23.74** When asked during the Oral Hearings what the ultimate aim of the BPL's research was, Dr Smith gave the following explanation of the attempt to remove fibrinogen:

[A]ll the time we had been working with Factor VIII, you are yearning to get rid of fibrinogen, and over ten years we were working continuously on every possible avenue which presented itself to us or in some publication to achieve that ....

So although this looks like pasteurisation in pursuit of killing non-A non-B Hepatitis, the aim of the gentle heating was solely to try and find a shortcut to reduce the amount of fibrinogen at a cost in Factor VIII which might be acceptable. It did not work.<sup>146</sup>

It was an attempt to achieve a more pure product with all the advantages that that would bring.

**23.75** There were close working relationships between the BPL and the PFC. The relationship went beyond Dr Smith and Dr Foster. Dr Cuthbertson and Dr Perry had close relationships with Dr Smith and Dr Snape, and later Dr Harrison.<sup>147</sup> But the relationship between Dr Smith and Dr Foster was particularly close. Mr Watt had heard Dr Foster speak at University College, London in 1970. He suggested to Dr Smith, then at the SNBTS, Edinburgh, that he should visit and discuss Dr Foster's research. Dr Foster gave further details of this stage which are set out later. He was recruited by Edinburgh and in and after January 1973 worked closely with Dr Smith until he left in 1975. They agreed to maintain close contact.<sup>148</sup> Their contacts, at professional level, were known to other managers at the PFC and the SNBTS and news and information gathered was passed on.<sup>149</sup> Dr Perry

<sup>146</sup> Dr Smith – Day 59, page 51

<sup>147</sup> Dr Cuthbertson – Day 46, page 43

<sup>148</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1457

<sup>149</sup> Dr Perry – Day 45, pages 24–25

noted that Dr Smith and Dr Foster were both recognised experts in their field and thought that there was nothing surprising or remarkable about the degree of disclosure.<sup>150</sup> Dr Cuthbertson never had any sense of being constrained in his contacts with colleagues in England. He said:

I think in those days probably at scientific and technical level we had slightly more freedom than we later had to actually indulge personal communications. I mean, it was well enough known that at senior management level there was not a meeting of minds between the directors of the two institutions but I think we all just worked round that rather than through it, if that makes sense.<sup>151</sup>

Dr Richard Lane and Mr Watt did not always see eye to eye. Within the SNBTS tensions between Mr Watt and Professor Cash did not inhibit scientific work either.<sup>152</sup> Externally, within the constraints of commerciality, there was free exchange of data and information with scientists in industry.

**23.76** Meanwhile, initial experiments led by Dr MacLeod into the pasteurisation of factor concentrates had led to what he referred to as 'good results' using sorbitol or sorbitol/glycine as stabilisers.<sup>153</sup> More work was, however, needed and investigations were underway into whether the SNBTS process was sufficiently distinctive and could be protected by patent.<sup>154</sup>

**23.77** Later in the year there was more correspondence between the PFC and the BPL on the subject of heat treatment, with Dr Foster writing to Dr Smith on 1 December 1982 outlining heat treatment experiments which the PFC had carried out on Factor IX. He enclosed a copy of Behring's patent, and an abstract relating to Hyland's work. He also discussed at some length the PFC's freeze-drying experiences.<sup>155</sup>

**23.78** When asked to describe the nature of cooperation between himself and Dr Foster at this time, Dr Smith explained in his written evidence:

I would characterise it as decidedly lopsided at this point, insofar as virus inactivation in F.VIII was concerned. BPL was in a delicate transitional condition and had few resources to tackle the problem seriously.

It was a correspondence between scientists with a clear sense of their responsibilities. We were both well aware of a degree of tension between the upper layers of our respective organisations but agreed (without as I recall having to discuss the question) that this must not be an obstacle to pooling what information we could each gather.

It will also be evident from [Dr Foster's letter of 1 December 1982] that, during my tenure at BPL Elstree, PFC visitors were welcomed and technical information shared openly. My colleagues and I invariably received an equally warm welcome from everyone at PFC and the rest of SNBTS.<sup>156</sup>

<sup>154</sup> Preliminary Report, paragraphs 11.87–11.89

<sup>155</sup> Dr Foster's letter to Dr Smith [SNB.007.3341]

<sup>156</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1556

**23.79** Dr Smith added during his oral evidence:

[T]here were very few telephone conversations. Most of the things we wanted to share with each other involved detailed evidence, as you see, and we would not present each other with rumours or rumours of rumours, which we knew would simply tend to confuse the other. We would wait until we had something which we could stand by and provide in sufficient detail to be useful to the other. We were not in each other's pockets or on the phone every other day. Most of it was done by detailed letters and topping up the background with the occasional visits.<sup>157</sup>

**23.80** Dr Foster characterised the nature of cooperation between himself and Dr Smith as follows:

- a). I had a very good relationship with Dr Smith and always found him to be extremely co-operative.
- b). I first met Dr Smith in 1970 when he visited me at University College London to discuss my PhD research. After joining the PFC in January 1973, I worked closely with Dr Smith until he left in August 1975. Before leaving the PFC, Dr Smith gave a number of seminars in which he very generously shared his knowledge and expertise. I then visited Dr Smith at the PFL (Oxford) in 1976, when we agreed to maintain close communication.
- c). One way of learning of progress elsewhere was to attend international conferences and symposia. As it was difficult for any one person to attend all of the conferences, Dr Smith suggested that we should share reports if one of us had attended a conference that the other had missed. Dr Smith did not attend the 1982 ISBT Congress and it was because of this arrangement that I sent my report ... to him.<sup>158</sup>
- d). I believe that it was on reading my report of the 1982 ISBT Congress that Dr Smith first learned that research was being undertaken on pasteurisation and dry-heat treatment of coagulation factors. It is therefore not surprising that only 'a *little*' research on heat treatment was being undertaken at PFL (Oxford) at November 1982.<sup>159</sup>

**23.81** The Inquiry also asked what degree of importance viral inactivation had in the research and development priorities of the BPL at this point. Dr Smith's response in his written evidence indicated that the Director of the BPL, Dr Lane, viewed NANB Hepatitis as 'a very serious problem in recipients of plasma products', but that 'there were many obstacles to tackling the problem, other than the local ones of resources in a difficult period at Elstree'.<sup>160</sup>

### **Clinical trials and commercial heat-treated products**

**23.82** A meeting took place at the BPL on 15 December 1982 to discuss the 'implications for the Haemophilia and Blood Transfusion Services of Commercial Introduction of "Hepatitis-Safe" Factor VIII and IX'. The minutes of the meeting reported on the expected

<sup>157</sup> Dr Smith – Day 59, page 62

<sup>158</sup> Dr Foster's report on the Budapest conference [SNB.010.4452]

<sup>159</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1457

<sup>160</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1556

introduction of commercial heat-treated concentrates into the UK market and expressed a need for, 'centralised, fully controlled prospective trials of "HS" materials, best operated through a properly executed National Clinical Trial lodged with the Regulatory Authority'. It was proposed that: (a) random exploitation of the haemophilia service by commercial organisations for the study of 'hepatitis-safe' products should be discouraged; (b) the haemophilia services should create a formal basis for controlled clinical trial of alleged 'hepatitis-safe' products in line with the requirements of the Medicines Act; (c) the haemophilia services, the PHLS and the NBTS should combine resources in a manner likely to advance economic treatment of NHS haemophilia patients with safe products.<sup>161</sup>

**23.83** Professor Cash's reaction to the proposals illustrated the difficult relationships between representatives of senior management from time to time. He described it as a 'very difficult' meeting. He felt that English colleagues were party to a proposition that UK clinical trials of the new products should be encouraged, to the advantage of England. He thought that the proposals were a sophisticated marketing exercise set up by US fractionators, and that the meeting had been designed to undermine the Scottish service's commitment to self-sufficiency and, though less obviously, collaboration between BTS and SNBTS scientists.<sup>162</sup>

**23.84** In his view the Scots were considered to be troublesome, not only by the commercial sector, but by the DHSS. Professor Cash believed that Scottish opposition to such a proposal would have been known. He was also somewhat upset that his co-operation was being sought when he had pressed without success for some years for a closer relationship between the two fractionators in research and manufacture.<sup>163</sup> He was anxious that the UK's small cohort of previously untreated patients should not be used to test US products and so be lost to clinical testing of domestic products. He recognised that the products required to be tested, but thought that that might be done in Italy or New York.<sup>164</sup>

**23.85** Professor Cash's evidence reflected his attitude at the time. He believed there was a lack of commitment at the level of senior management of the National Blood Transfusion Services in the two countries to integration of research and production. Professor Cash commented that relationships between Mr Watt and Dr Lane were seriously strained.<sup>165</sup> He thought Dr Smith had left the PFC after falling out with Mr Watt.<sup>166</sup> He himself had serious disagreements with the BPL management.<sup>167</sup> Professor Cash was never sure how far Dr Smith had the support of senior management with regard to his collaboration with Dr Foster.<sup>168</sup> Professor Cash commented that he had lost control at the meeting, and that discussion had become heated.<sup>169</sup>

**23.86** Following this meeting, Professor Cash sent Dr Lane a letter dated 17 December 1982,<sup>170</sup> with a copy to Dr Harold Gunson, in which he outlined his objections to the course of action proposed. In his letter Professor Cash indicated that:

<sup>161</sup> Minutes of meeting [DHF.003.0059]. The meeting was attended by Professor A Bloom, Dr C Rizza, Dr H Gunson, Dr J Craske, Dr R Lane and Dr M Harvey, as well as Professor Cash of the PFC and Dr Smith of BPL/PFL. See also Preliminary Report, paragraph 11.90.

<sup>169</sup> Professor Cash – Day 43, page 31

<sup>170</sup> Professor Cash – Day 43, pages 31–32; Professor Cash's letter [SNB.004.3163]

I do not believe it is in the best interests of the NHS Fractionation Centres, at this time, to encourage the commercial manufacturers to undertake clinical trials with a view to obtaining product licences ....

I would therefore conclude that, at the present time, it is in our (British Transfusion Services) best interests to permit the commercial people all the freedom they desire. I fully sympathise with the sentiments expressed at our meeting, but I am totally convinced that the proposed action is tactically wrong at this time, and will have serious consequences for us all if pursued.

The solution to our problem rests, as I said at the meeting on the 15th December, in thinking and acting very much more positively – I refer to the problem of getting BPL and PFC to work together at all levels. I now deeply regret that the joint PFC/BPL meeting on factor VIII concentrates that I proposed in a letter to you dated 19th December, 1980 did not take place. However, we must now surely consider this as ‘water under the bridge’ and get down to the urgent task of bridge building. I’m bound to conclude that up to the present time we, as professionals, have failed and the time has come for a joint meeting of the top managers. I include in this context senior members of our respective employing authorities. It is my intention to see what I can do to build these bridges. I do not regard the existing furtive arrangements, as regards factor VIII, between Jim Smith and Peter Foster, however good they may be, as a sound basis upon which the NHS fractionators can combat the commercial people.

**23.87** Dr Lane replied to Professor Cash on 21 December 1982 suggesting that it had been agreed that: ‘Arthur Bloom and Charles Rizza should inform the Haemophilia Directors of their reasonable right to know the proper basis supporting manufacturers’ claims of safety for products in connection with hepatitis-reduced Factor VIII now about to reach the UK market’ and informing Professor Cash that: ‘since you clearly have altered your view since the meeting, it would seem right that your letter should have been addressed to the Chairman or at least copied to him, since he might feel that further discussion was necessary’.<sup>171</sup> Professor Cash replied on 29 December 1982, in more conciliatory terms, suggesting that ‘perhaps the best way forward would be for you to discuss the matter with Harold and feel entirely free to further discuss the problem with Arthur, if you so wish’.<sup>172</sup>

**23.88** The correspondence between Professor Cash and Dr Lane following the meeting of 15 December 1982 indicated a degree of tension between the BPL and the PFC concerning the approach to be taken with regard to the likely introduction of commercial heat-treated products and, more generally, as regards cooperation/bridge-building between the BPL and the PFC on viral inactivation (and in particular the relationship between Dr Foster and Dr Smith).<sup>173</sup> There is a problem with Professor Cash’s position generally that was highlighted by Professor van Aken: there was a conflict of interest inherent in Professor Cash advising government on the approach to adopt to commercial producers in a competitive market, and in heading the SNBTS which was a producer of products in that market.<sup>174</sup> The Netherlands had a different administrative and licensing structure.<sup>175</sup>

<sup>171</sup> Dr Lane’s letter [SNB.004.3160]. It is clear from [SNB.004.3159] that the Chairman of the meeting held on 15 December 1982 was Arthur Bloom.

<sup>172</sup> Professor Cash’s letter to Dr Lane [SNB.004.3159]

<sup>174</sup> Professor van Aken – Day 47, page 65

<sup>175</sup> Professor van Aken – Day 47, pages 66–68

**23.89** Professor Cash's conclusion that it was in the best interests of the British Transfusion Services to permit commercial producers all the freedom they desired, which might have included sale of commercial products without clinical trials in the UK, might have conserved the British haemophilia population for trial of domestic products, but that would have been a particularly partial case to advance.

**23.90** Professor Bloom and Dr Rizza wrote to the Haemophilia Centre Directors on 11 January 1983 indicating that the Hepatitis Working Party was discussing plans for clinical trials of these products.<sup>176</sup> On 10 January, the Public Health Laboratory Service (PHLS) wrote to the DHSS enclosing a draft letter intended for publication in *The Lancet* supporting prospective trials of commercial products.<sup>177</sup> It appears that by the end of March 1984 clinical trials had been completed of one product, Hemofil HT, at St Thomas' hospital in London.<sup>178</sup> The Scottish response to the invitation to participate in clinical trials of the commercial products is discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*, at paragraphs 15.143 to 15.144. Professor Christopher Ludlam refused to participate.<sup>179</sup> Professor Cash promoted a Scottish study of patients who had received PFC heat-treated products. The difference in interests between Scotland and the rest of the UK, which had its origins in the dependence of England and Wales on imported products and Scotland's commitment to self-sufficiency, was implicit in these developments.

### Evidence on state of cooperation between Dr Foster and Dr Smith

**23.91** Professor Cash also expanded in his written evidence on what was meant by the mention in his letter of 17 December of 'the existing furtive arrangements' between Dr Foster and Dr Smith, noting that:

There is no doubt that when I look in 2010 at the proposition that Peter Foster and Jim Smith's interactions were 'furtive', an apology is due. I'm afraid the temperature in this meeting got too high and some of us became extremely anxious that all the SNBTS had stood for was to be swept aside by market place considerations. I suspect that Jim Smith and Peter Foster were aware that in 1980 I had sought to persuade Jim's boss (Dr Lane) that we really ought to be making collaboration between BPL and PFC open, intensive and a high priority, and that this proposal had been rejected. Despite this, and at that time unknown to me, Dr Smith elected to work closely with former PFC colleagues.<sup>180</sup>

**23.92** During his oral evidence Professor Cash was asked whether 'furtive' was perhaps simply the wrong word and replied as follows:

Yes, I have no hesitation. I think the fundamental problem I had – and it wasn't about Peter and Jim Smith – it was about: how did the SNBTS as a whole – this working group that we talked about – get engaged in the area of fractionation?

<sup>176</sup> Professor Cash – Day 43, pages 49–51; Professor Bloom and Dr Rizza's letter [DHF.003.0892]. Note that the date recorded on the letter (11 January 1982) would appear to be incorrect and that a date one year later (11 January 1983) appears correct: see Inquiry Counsel's explanation – Day 27, pages 47–51

<sup>177</sup> Letter from PHLS to DHSS [DHF.001.7106]

<sup>178</sup> Professor Cash – Day 43, pages 39–42; Colombo et al, 'Transmission of non-A, non-B Hepatitis by Heat-treated Factor VIII Concentrate', *The Lancet*, 6 July 1985; 1–5 [LIT.001.0369]. And see Memorandum to Haemophilia Centre Directors of 29 March 1984 [DHF.002.8963]

<sup>179</sup> Professor Ludlam's letter to Miss Spooner of 10 April 1984 [SNF.001.3211]

<sup>180</sup> [PEN.012.1912] at 1919

And that was difficult because it was heavily controlled by John Watt and so on, and I felt that Peter and Jim were often in bed. So I didn't regard them as being furtive ....<sup>181</sup>

Professor Cash added that he supported what was going on, and that Dr Smith and Dr Foster were getting on with the work.<sup>182</sup>

**23.93** Professor Cash's concerns appear to have been related not to the state of the cooperation between Dr Foster and Dr Smith itself, but rather to the lack of a formal structure surrounding their cooperation. Professor Cash also appears to have been impressed by Dr Foster's abilities, going so far as to note at one point during his evidence – admittedly with exaggeration – that, 'if we had had 25 Peter Fosters, we would have been fractionating on the moon'.<sup>183</sup>

**23.94** Dr Foster's written evidence to the Inquiry also expressed the view that the issue raised by Professor Cash at the time was the lack of a formal structure for cooperation rather than any breakdown in cooperation with the BPL and Dr Smith.<sup>184</sup>

**23.95** Dr Foster's written evidence indicated, however, that his preference was 'to exchange information with Dr Smith and his staff on a less formal basis than Professor Cash may have preferred', although he 'would have been happy to accept a more formal arrangement, if this had been requested'.<sup>185</sup> When asked to expand on this point during the Oral Hearings, Dr Foster said that with scientists who are dealing with the same problems, talking face-to-face was the best way to proceed in terms of communications, over the phone and having meetings, and obviously in correspondence, and in reciprocal visits to each other's facilities.<sup>186</sup>

**23.96** When asked, both Dr Foster and Dr Smith confirmed that, in their view, the reporting between the PFC and the BPL was reciprocal. Dr Foster noted in his written evidence that:

To the best of my knowledge the exchange of information between the SNBTS and the BPL/PFL was reciprocal, except when precluded by a requirement for confidentiality, such as the arrangements between the PFC and Dr Johnson ... and the period when BPL were planning to patent the process used to prepare 8Y ....<sup>187</sup>

**26.97** Dr Smith's response was:

I would have continued to inform PFC without constraint of anything notable coming out of our still very tentative work on pasteurisation, and later dry-heating, in 1983. But I cannot document that.<sup>188</sup>

---

<sup>184</sup> See also Dr Perry's statement on viral inactivation to 1985 for a similar view – [PEN.012.1759] at 1766

<sup>185</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1460

<sup>186</sup> Dr Foster – Day 41, pages 140–141

<sup>187</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1461

<sup>188</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1558

**23.98** Dr Perry said:

Although there continued to be no formal collaboration or reporting between Scotland and England the established cooperation continued particularly between senior operational managers at PFC (myself and Dr Foster) and their counterparts at BPL (Drs Smith and Snape).<sup>189</sup>

Dr Perry's most important contribution on this issue was that it did not have any impact on the local PFC development programme, which continued to focus on the development and preparation of a pasteurised product for initial clinical trial.<sup>190</sup> He emphasised that it was important to recognise that the pursuit and maintenance of self-sufficiency and product yield were of high priority for the SNBTS, particularly in light of the knowledge that the eventual introduction of NHS heat-treated products would, as a result of yield penalties, potentially reduce the overall amount of Factor VIII available to patients.<sup>191</sup>

**23.99** Notwithstanding the written exchanges, and the background of difficult relationships among senior management of the public sector organisations which they reflect, Dr Smith and Dr Foster continued their dialogue.<sup>192</sup> In addition, there were more formal joint projects involving the two organisations.<sup>193</sup> In the ordinary course of business, the exchange of information was reciprocal except where there was a requirement for confidentiality, arising from external contracts or from patent proceedings.<sup>194</sup>

**23.100** On a wider front, informal contacts with scientists in the pharmaceutical industry provided intelligence on developments that were not widely publicised. Dr Prowse of the PFC had thus heard that Baxter/Hyland's product disclosed at Budapest was dry heat-treated.<sup>195</sup> After testing, the dry heating applied to Hemofil T proved less effective than pasteurisation.<sup>196</sup> That was consistent with information circulating informally within the industry, and within UK Government circles, in 1983 and 1984.<sup>197</sup> It appears that while regulatory reporting on Hemofil awaited completion of the formal studies required by International Society of Blood Transfusion (ISBT) protocols, dissemination of the adverse results was a priority for researchers.

**23.101** Against this background of increased industry interest in heat treatment, the PFC (Dr Cuthbertson and Dr Pepper) did some experiments in dry heat treatment of Factor VIII.<sup>198</sup> Meanwhile, work on pasteurisation continued. There was considerable activity at the beginning of 1983 (summarised in paragraphs 11.96 to 11.115 of the Preliminary Report), leading up to the agreement of Professor Forbes and Professor Ludlam on 22 March 1983 to take part in clinical trials of the PFC Factor VIII product as part of a strategy for developing heat-treated products for general use.<sup>199</sup> However, within a few weeks AIDS among haemophilia patients in the USA was widely publicised and the context

<sup>189</sup> Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1767. Dr Perry agreed during his oral testimony (Day 45 – page 35) that the order of Drs Smith and Snape should be reversed so as to reflect the correct counterparts at the PFC and the BPL. Dr Perry also noted that Dr Snape was the quality assurance manager at the BPL.

changed from elimination of NANB Hepatitis. Developments in 1983 are considered in the context of that new threat.

**23.102** The change of emphasis was reflected in the Netherlands also. Professor van Aken said of the early 1980s:

The growing concern was mainly related to AIDS and with regard to non-A, non-B hepatitis that was at that time more or less, I would say, accepted as a side effect of transfusion and of the administration of plasma components. That had not the same urgency as it gradually got later on because in the beginning, when I came in board in CLB on the board, that was not the main concern we had. The first real concern about transmission of the diseases, of viral diseases, was AIDS.<sup>200</sup>

### Research at the Protein Fractionation Centre: Progress in 1983 and 1984

#### 1983

**23.103** In the first few months of 1983 the PFC continued its work on the pasteurisation of Factor VIII. Dr Foster reported on developments to Dr Smith and the PFC appears to have been keenly aware that commercial companies were likely to launch heat-treated Factor VIII in the near future.<sup>201</sup> In a memo to Mr Watt, Heads of Department, Section Managers and Dr MacLeod dated 11 January 1983, Dr Foster explained that 'this could well have major implications for the NHS ... and it is therefore recognised that there is some urgency in demonstrating that the NHS has the capability to manufacture products of this kind'.<sup>202</sup> Clinical trials of small amounts of high purity zinc-precipitated Factor VIII which had been heated at 60°C for 10 hours were planned with the aim of developing a product with a 'reduced risk of transmitting hepatitis'.<sup>203</sup> During the meeting of the Haemophilia and Blood Transfusion Working Group on 22 March 1983, it was decided that Professor Charles Forbes and Professor Ludlam were to carry out these trials in coordination with Professor Cash.<sup>204</sup>

**23.104** As regards Factor IX, research into heat treatment to reduce the risk of hepatitis was reported to be underway.<sup>205</sup> However, it was noted that animal studies would be needed in order to confirm that heat-treated Factor IX was not thrombogenic.<sup>206</sup>

#### Recognition by fractionators of the risks posed by AIDS

**23.105** During the first few months of 1983 the focus of the PFC's research and development programme remained on methods which could inactivate hepatitis in blood products. However, a subtle shift had begun to take place. Fractionators were becoming alive to the possible risks which AIDS might pose to the blood supply (and hence the possible enhanced need for viral inactivation processes which could deal with such risks).

<sup>200</sup> Professor van Aken – Day 47, pages 74–75

<sup>201</sup> See letter from Dr Foster to Dr Smith dated 20 January 1983 including technical details of the PFC's work on pasteurisation [SNB.007.3407]

<sup>205</sup> Minutes of the meeting of Directors of the SNBTS and Haemophilia Directors of 21 January 1983 [SNB.001.5160] at 5164

<sup>206</sup> Minutes of the meeting of Directors of the SNBTS and Haemophilia Directors of 21 January 1983 [SNB.001.5160] at 5164. See also the memo from Dr Foster to Mr Watt and Dr Perry dated 17 February [SNB.007.3474] in which Dr Foster proposed setting up a dog colony to test for thrombogenicity. For further details of the period January–April 1982 see Preliminary Report, paragraphs 11.96–11.115.

**23.106** This issue of AIDS was referred to very briefly (admittedly with a question mark) as a ‘problem’ in a presentation entitled ‘Methods for Preparing Non-infective Blood Products’ given by Dr Foster to the Haematology Department of the Royal Infirmary of Edinburgh (RIE) on 8 March 1983.<sup>207</sup> When asked to expand on what this meant, Dr Foster explained that he was beginning to think that AIDS might be caused by an infectious agent that would potentially have to be taken into consideration in research on virus inactivation: research was not going to be focusing exclusively on hepatitis.<sup>208</sup>

**23.107** AIDS was also discussed (in general terms and in the context of high-risk donors) during the meeting of the Haemophilia and Blood Transfusion Working Group on 22 March 1983, the minutes of which note that members were reminded of the recent articles both at home and abroad about AIDS, and that there was concern that AIDS might appear in the UK.<sup>209</sup> However, there is no record that the potential impact of AIDS on the PFC’s viral inactivation programme was discussed. According to Dr Perry, the apparent lack of a cross-reference between AIDS and heat treatment in this discussion was unsurprising as, in his view, ‘at that time it was far from established or accepted that AIDS had a virus aetiology’.<sup>210</sup> Dr Foster was of the same view, although his oral evidence on his presentation of 8 March 1983, referred to at paragraph 23.106 above, indicates a degree of ambivalence. He stated in his written evidence:

At this time (22 March 1983), the cause of AIDS was not known. Even if an infectious agent was assumed to be responsible, neither the nature of the infectious agent, nor its sensitivity to heat were known. Therefore there was no basis, other than speculation, for a ‘cross-reference’ between the topics of heat treatment and AIDS.<sup>211</sup>

**23.108** Dr Perry advanced another possibility for the lack of a cross-reference between AIDS and heat treatment in the minutes of this meeting. According to Dr Perry, the failure to make a connection between these two issues in the minutes did not necessarily imply that the meeting had not discussed the two potentially related topics. He suggested instead that it seemed more likely that any such discussion had been inconclusive and therefore had not been recorded.<sup>212</sup> Professor Cash, in contrast, was of the view that the lack of a reference was to be expected indicating that, ‘heat treatment was a process that was assumed might inactivate all viruses transmitted by plasma products. Thus in March 1983 a specific link between the two would have been taken for granted’.<sup>213</sup>

**23.109** Only a few weeks later, in May 1983, the potential impact of AIDS on the PFC’s strategy had become more apparent. On 3 May 1983 Dr Foster sent a memo entitled ‘Heat Treatment of FVIII. A strategy’ to Mr Watt and the PFC’s Heads of Department.<sup>214</sup> The memo indicated that:

Until very recently the objective of our heat treatment programme was to cope with the hepatitis problem in haemophiliacs.

Because severe haemophiliacs have already been heavily exposed to untreated products then only mild and moderate haemophiliacs could benefit from a

<sup>214</sup> Dr Foster’s memorandum [SNB.007.3635]

treated product (in the foreseeable future). It was estimated that the mild/moderate group could use up to 30% of the total FVIII. This estimate, plus the fact that these patients are presently likely to be treated with single donor cryoprecipitate have determined our present strategy i.e. that we will:

- (1) Plan for 4–6 pilot scale lots during 1983.
- (2) Design a full-scale plant to handle 30% production for 1984/85 at the earliest.
- (3) Mild and moderate haemophiliacs can continue to receive single donor cryo meanwhile.

The possibility that another more serious infectious agent (AIDS) is now involved suggests that we may need to review this strategy. In the new scenario:-

- i) The haemophiliacs most at risk are the severes rather than the mild and moderates.
- ii) There is already evidence of a panic recourse to cryoprecipitate.

In the absence of any hard data, heat treatment (of everything) looks at the moment to be the most likely possibility that we have to face up to. If this is so then we will have to plan to pasteurise all of the FVIII (rather than 30%) and we may also want to review the timescales noted above.

**23.110** The memo indicated further that decisions will probably be taken according to a 'worst case' hypothesis and suggested that:

There may therefore be a case for accelerating our heat treatment programme. While I do not disagree with point (2) above it may be possible to introduce an intermediate stage, still using the pasteurisation cabinets. We probably have most of the equipment to do this already.<sup>215</sup>

**23.111** A worked example followed outlining how this 'intermediate stage' would operate in practice based on an input of 1000kg of fresh frozen plasma.

**23.112** Two days later, on 5 May, Mr Watt wrote to Professor Cash.<sup>216</sup> His letter outlined the existing pilot-scale approach to heat treatment and preliminary results of heat treatment studies which showed that heating for a shorter period at a higher temperature (70°C for less than an hour) was more effective in killing virus than heating for 60°C at 10 hours. The letter also advocated an acceleration of the pasteurisation programme, noting that:

In view of recent news exposure of (?) [*sic*] infectivity of Factor VIII concentrates we have made a re-assessment of heat treated concentrate based on a careful step-by-step appraisal of a series of pilot-scale lots.

In most areas of the development I believe we now possess sufficient data to allow, by adopting a few calculated risks, this programme to be speeded up substantially .... My colleagues are engaged in a costing for the expedited programme in case public opinion rather than science may dictate the best course of action.<sup>217</sup>

<sup>215</sup> The memo included Dr Foster's tentative suggestions as how such a process would operate [SNB.007.3635] at 3636

<sup>216</sup> Mr Watt's letter [SNB.007.3638]

<sup>217</sup> Mr Watt's letter [SNB.007.3638] at 3640

**23.113** Professor Cash responded to this letter on 1 June 1983 noting that he considered the last part of Mr Watt's letter (ie the proposal to accelerate the heat treatment programme) to be the most important and that 'as you say, public opinion may eventually press us heavily'.<sup>218</sup> However, the letter also indicated that there were insufficient funds:

Right now we must conclude that with the existing set of instructions the Agency [the CSA] has received from SHHD with regard to the way it is to spend its development monies, and noting the reaction of the Deputy Chief Medical Officer to the concept that heat treated factor VIII is related to the interests of the Medicines Inspectorate, then there are no funds available in 1983–1984 for your proposals. However, in the light of the current pressures (AIDS etc.) the Department may wish to reconsider its instructions to the CSA and/or find additional monies (less likely!). In any event, I think we can be certain that a full and separate case will be required by the SHHD as soon as possible and your Report on PFC's needs will be of considerable importance.

**23.114** The letter drew Mr Watt's attention to two 'inextricably linked items' ('implications for PFC of optimal additive blood bags' and 'pilot stage of heat-treatment of factor VIII') and went on to ask Mr Watt to 'take these two items' and 'put them together in a single package (story) directed towards the heat treatment of factor VIII' – ie a proposal which could be put before the SHHD.

**23.115** The Inquiry asked various witnesses questions focused on gaining an understanding of: the circumstances which led Dr Foster to write his memo of 3 May 1983; the plans outlined in this memo; the subsequent correspondence between Mr Watt and Professor Cash; and the plan to seek more funds from the SHHD for the acceleration of the pasteurisation programme.<sup>219</sup>

**23.116** In his written evidence,<sup>220</sup> Dr Foster explained that the trigger for his memo was the report in *The Lancet* of 30 April 1983 of AIDS infections in 11 haemophiliacs in the USA and three in Spain who had been treated with commercial factor concentrates.<sup>221</sup> According to Dr Foster, 'these reports caused me to consider the potential implications for our strategy on the development of heat treatment, should it be found that this syndrome was caused by an infectious agent'.<sup>222</sup> Severe haemophiliacs were more at risk of AIDS as they 'received much more treatment'.<sup>223</sup>

**23.117** Dr Smith's view was that, at this time, most fractionators thought it likely that AIDS was caused by a blood-borne virus, indicating that Montagnier and Barré-Sinoussi's seminal article of 20 May on the isolation of the HIV virus<sup>224</sup> offered 'strong support' for this 'working hypothesis'.<sup>225</sup> The Montagnier/Barré-Sinoussi article post-dated Dr Foster's memo and could not have been something he would have been aware of in preparing his

<sup>218</sup> Professor Cash's response [SNB.007.3708]

<sup>225</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1559

memorandum of 3 May.<sup>226</sup> Dr Smith further explained in his oral evidence that the insight that he had at this time (based on information probably provided by Dr Cumming) was that:

[There was] a huge overlap between the sexually transmitted diseases and the blood borne diseases. So anyone with that mindset would tend to be making a conclusion perhaps before the evidence really justified it.<sup>227</sup>

**23.118** Professor Cash also confirmed in his written evidence that the threat of AIDS was becoming clearer by May 1983, noting that:

As far as I recall, by May 1983 we were a little more certain that AIDS was transmitted by plasma products and that the clinical consequences were very much more serious than viral hepatitis. It follows that Dr Foster's reported efforts to accelerate our heat treatment programmes were entirely appropriate.<sup>228</sup>

**23.119** In his oral evidence, Dr Foster explained how the plan outlined in his memo of 3 May 1983 was intended to operate. He noted that he had difficulty recollecting exactly what he meant by the introduction of an 'intermediate stage' for the acceleration of the heat treatment programme.<sup>229</sup> However, when asked, he indicated that the phrase should be read as meaning a plan which could advance heat treatment as quickly as possible<sup>230</sup> and that, in practice, this meant a 'temporary arrangement pending the fully engineered process design' (ie pending the design of a full-scale plant).<sup>231</sup> The plan would, therefore, have amounted to a wholesale move to pasteurisation using the existing pasteurisation cabinets, albeit on a temporary basis.<sup>232</sup>

**23.120** Dr Foster gave further background information in his written statement. He indicated that the original plan for the pasteurisation process involved 'heating large volumes of protein in a concentrated sugar solution' in a single large vessel, but that:

[E]arly large-scale experiments demonstrated that the heating-up and cooling-down of the mixture took a very long time, during which more factor VIII was destroyed than had been experienced in small-volume laboratory experiments.<sup>233</sup>

**23.121** To prevent this loss of Factor VIII, Dr Foster considered the design of a recirculating system in which the solution would be passed through a heat exchanger to accelerate heating-up and cooling-down. However, according to Dr Foster, this was not straightforward. An alternative process was adopted which involved 'dispensing the mixture into 1 litre bottles which could then be heat-treated in the PFC spray cabinet that was used to pasteurise albumin'. Dr Foster explained that this procedure enabled pilot-scale production of Factor VIII to be accelerated.<sup>234</sup> This pilot-scale process did not extend to the wholesale switch to pasteurisation using pasteurisation cabinets which was proposed in his memorandum of 3 May 1983.<sup>235</sup> As outlined further below in the discussion of the events of 1984, wholesale switch to pasteurisation ultimately never occurred.

## Funding issues

**23.122** The Inquiry posed various questions to witnesses aimed at clarifying the outcome of Professor Cash's request in his letter of 1 June 1983 for the PFC to put together a funding proposal for the heat treatment programme.

**23.123** In summary, the position appears to have been as follows:

- At the end of May 1983, the Blood Transfusion Service Sub-Committee of the Common Services Agency (CSA) agreed that a funding proposal for the 'pilot stage of heat treatment of factor VIII' should be submitted to the SHHD as a bid against certain of the money available to meet the costs of the recommendations arising from the Medicines Inspectorate inspection of the PFC.<sup>236</sup> The reason for attempting to link heat treatment to the recommendations of the Medicines Inspectorate appears to have been largely a pragmatic one, based on the fact that a large sum of money (circa £650,000) had already been allocated for compliance with the Medicines Inspectorate's recommendations relating to the quality of the PFC's facility.<sup>237</sup>
- A proposal was duly submitted by the CSA to the SHHD in June 1983.<sup>238</sup> The funding sought for the heat treatment of Factor VIII was for capital of £74,000 for equipment and £13,400 revenue.<sup>239</sup>
- In September 1983, the SHHD responded that the expenditure on heat treatment was not a requirement arising from the recommendations of the Medicines Inspectorate, but asked the CSA to consider making a separate submission for funding.<sup>240</sup>
- On 22 February 1984, the Blood Transfusion Service Sub-Committee approved a separate submission to the SHHD for funding for the heat treatment of Factor VIII.<sup>241</sup>
- On 23 May 1984, Dr Albert Bell of the SHHD wrote to Mr Alexander Murray (also SHHD) outlining the policy case for the heat treatment of Factor VIII, concluding, '[I]t is not for me to say how this development should be financed but I can say that it is a genuine technological advance and a failure to bring it about would be very difficult to defend'.<sup>242</sup>
- Formal authorisation of a sum of £90,000 for the heat treatment of Factor VIII was ultimately made by the SHHD in mid-August 1984.<sup>243</sup>

**23.124** There was, therefore, a delay of more than one year between the submission of the initial request for funding for heat treatment of Factor VIII and the authorisation of the amount requested, arising largely from these administrative exchanges.<sup>244</sup> Funding was one of the few aspects of the SNBTS operations in which the CSA and its committees had an active role.

<sup>243</sup> Letter from Dr Perry to Mr Wooller, dated 13 August 1984 [SNB.007.4523] and Mr Wooller's response, dated 17 August 1984 [SNB.007.4527]

<sup>244</sup> Dr Perry – Day 45, pages 39–56 and Professor Cash – Day 43, pages 56–79 for more details on the issue of funding.

**23.125** An important question is whether this delay in the authorisation of funding resulted in a delay to the heat treatment programme. According to the witnesses asked this question by the Inquiry, the heat treatment development programme was not delayed. Dr Perry stated in his written evidence that: ‘my recollection is that notwithstanding the above funding issues concerning scale up of production and its routine introduction the development programme continued to progress at pilot scale within existing resources’.<sup>245</sup> Dr Foster echoed this view in his oral evidence:

Q. But just before we drop for today the question of funding, do you have any memory of its also being an obstacle ... that money had to be found?

A. No, it didn’t seem to me to be an issue. I thought this is so important that I thought, ‘If this is what it costs, this is what it costs and the money will come through,’ and I left that to Mr Watt and Professor Cash to sort out. It wasn’t something that seemed to me to be an obstacle.<sup>246</sup>

**23.126** During his oral evidence, Professor Cash ‘instinctively’ concurred with Dr Foster’s view.<sup>247</sup>

**23.127** Both Dr Perry and Dr Foster also explained that, in their view, the key factor which determined the progress of the pasteurisation project in the latter half of 1983 was the organisation and conduct of clinical trials and not funding.<sup>248</sup>

### Progress at PFC

**23.128** Meanwhile, on 13 June 1983 Professor Cash wrote a letter to Professor Ludlam asking him to carry out clinical trials of the first batch of pasteurised Factor VIII (batch NY 761).<sup>249</sup>

**23.129** On 15 June 1983 a meeting of the Factor VIII Safety Action Group was held, which was attended by Dr Bruce Cuthbertson, Dr Bobby Sommerville and Dr Duncan Pepper. The minutes of the meeting provide a detailed overview of the research which the PFC was undertaking at this time, which involved heating at 60°C for 10 hours followed by a 30 minute period at 70°C and testing for virus kill (using vaccinia, polio 2 and herpes simplex as model viruses) and Factor VIII loss.<sup>250</sup> The research was summarised as follows:

Considerable progress has been made at P.F.C. in producing heat treated FVIII and clinical trials should start towards the end of the summer in Glasgow and Edinburgh. No infectious model for non-A, non-B has been produced yet. The putative ‘AIDS’ virus must be considered as a potential hazard in FVIII concentrates.<sup>251</sup>

**23.130** On 27 June 1983 Dr Foster met Dr Johnson at a World Federation of Hemophilia meeting in Stockholm and learned of a potentially promising method which could be used to increase the purity of Factor VIII.<sup>252</sup> Dr Foster explained in his written evidence that the process:

<sup>245</sup> Dr Perry – Day 45, pages 54–55; Dr Perry’s statement on viral inactivation to 1985 [PEN.012.1759] at 1769

<sup>250</sup> Minutes of FVIII Safety Sub-Committee, 15 June 1983 [SNF.001.3730] at 3731

<sup>251</sup> Minutes of FVIII Safety Sub-Committee, 15 June 1983 [SNF.001.3730]; Preliminary Report, paragraphs 11.130–11.134

<sup>252</sup> SNBTS Briefing Paper on the Development of Heat Treatment of Coagulation Factors [PEN.013.1309] at 1364

[I]nvolved the chromatographic purification of factor VIII, in which chemicals were added to subtly modify the conformation of the factor VIII molecule to promote its attachment to a conventional ion exchange matrix.<sup>253</sup>

**23.131** In practical terms this meant that:

[I]t was conceivable that the increased purity promised by the method of Dr Johnson would enable the volume of solution to be pasteurised to be reduced about 50-fold, making the pasteurisation in 1 litre bottles potentially feasible for full-scale manufacture as well as for pilot-scale processing.<sup>254</sup>

**23.132** Dr Foster passed on this information to Mr Watt who wrote to Dr Johnson on 1 August 1983, proposing collaboration (initially on a confidential basis) and outlining various procedural issues which would have to be dealt with.<sup>255</sup> The letter to Dr Johnson also intimated Mr Watt's decision to leave the PFC on grounds referred to as 'multifactorial'.<sup>256</sup>

### Infectivity of Hyland product

**23.133** Meanwhile, on 1 July 1983, Dr Diana Walford of the DHSS wrote to Dr Harold Gunson of the Regional Transfusion Centre (RTC) in Manchester indicating that three chimpanzees given Hyland's dry-heated Factor VIII product had developed hepatitis.<sup>257</sup> It would appear that the reference to hepatitis in this letter meant Hepatitis B.<sup>258</sup> The suggestion was that Hyland's product might not be hepatitis-safe. It is not clear at exactly what point this information filtered through to the PFC for the first time. However, it is clear that Hyland had already proposed a study during the World Federation of Hemophilia meeting in Stockholm in June to evaluate whether its dry-heated Factor VIII product transmitted hepatitis.<sup>259</sup> Professor Mannucci of the University of Milan took part in this study which was carried out in Milan, Heidelberg, Paris and London, and noted in his 2003 memoirs that:

[I]t was evident from the follow up of the first few patients enrolled in our study that a large number of them had developed hepatitis. Such information was verbally communicated by me to a large number of hemophilia treaters who met in Barcelona on the occasion of the Congress of the European Society of Haematology in September 1983.<sup>260</sup>

**23.134** The ultimate outcome of the research carried out by Professor Mannucci and others into the safety of the Hyland product, which was published in July 1985, was that patients given Hyland's dry-heated product had a high prevalence of NANB Hepatitis and an absence of Hepatitis B, whereas for chimpanzees the results were the reverse (ie an absence of NANB Hepatitis and a prevalence of Hepatitis B). So, in simple terms, the fact that a chimpanzee which had been given Hyland dry-heated Factor VIII was free from NANB Hepatitis provided no guarantee that the product would not transmit NANB

<sup>260</sup> Mannucci, 'AIDS, hepatitis and haemophilia in the 1980s: memoirs from an insider', *Journal of Thrombosis and Haemostasis*, 2003; 1:2065–69 [LIT.001.1101] at 1103

Hepatitis to humans. The conclusion of Professor Mannucci's research was therefore that, 'the animal model is not reliable for NANB hepatitis transmission studies'.<sup>261</sup>

**23.135** The results of the research were already widely known before publication in 1985. By late summer 1983, knowledge of the failure of the Hyland dry-heated product to inactivate hepatitis appeared to be fairly widespread. By January 1984, the SNBTS was certainly aware that the Hyland product was infective as evidenced by the minute of the meeting of the Factor VIII Study Group of 12 January 1984 which indicated that 'the current Hyland product ... is still infective'.<sup>262</sup>

### Progress in England

**23.136** By late July 1983, consideration by the authorities in England of their own approach to heat treatment was ongoing. A report by Dr Craske, which was subsequently incorporated into the annual report of the UK Haemophilia Centre Directors Hepatitis Working Party for 1982–83, included a general overview of the viral inactivation landscape outlining the various forms of viral inactivation which were being developed (ie using chemicals, pasteurisation and dry heat treatment), and the commercial heat-treated products which were likely to become available. The report commented that it was possible that Factor VIII concentrate prepared from plasma donations obtained in the USA might be contaminated with a putative infectious agent associated with the cause of AIDS.<sup>263</sup> It did not, however, suggest a specific direction which should be taken.

**23.137** An unpublished Central Blood Laboratories Authority (CBLA) paper on heat treatment dated 26 July 1983 did comment on the direction which was likely to be taken in England, though for marketing rather than purely scientific reasons.<sup>264</sup> It noted that pasteurisation was 'more homogeneous and efficient' than dry heat treatment, but that it was 'associated with more molecular damage of heat unstable proteins than occurs by the dry heat route' and appeared to favour dry heat treatment on the basis that this 'will allow BPL to present to clinical managers of haemophilia a product carrying equivalent weight of claims for safety as those of rival commercial organisations'. The report also indicated that 'it [had] been shown possible to maintain greater than 95% of factor VIII activity in the finished product after heating at 75°C for ten hours or heating at 60°C for 24 hours' and that this dry-heated product was 'being advanced with high priority to enable manufacture to become routine by the late summer 1983'. At this point, therefore, shortly before Mannucci was giving preliminary indications of the lack of efficacy of the dry-heated Hyland product in Barcelona, dry heat treatment was the preferred viral inactivation process in England.

**23.138** Various witnesses commented critically on aspects of the CBLA report of 26 July 1983. Dr Smith did not know who had written it and indicated that the date for routine manufacture of 'summer 1983' was 'extraordinarily optimistic' as by 'late summer 1983 we only had our very first results on dry heating'.<sup>265</sup> Dr Smith also pointed out that, while correct in principle, the reference to pasteurisation being 'associated with more molecular damage' had to be read loosely as one would not pasteurise or dry heat in the same

<sup>261</sup> Colombo et al, 'Transmission of NANBH by heat-treated factor VIII concentrate', *The Lancet*, 1985; 2:1–4, [LIT.001.0369] at 0371. See Dr Cuthbertson – Day 46, pages 59–61 for discussion of the failure of the chimpanzee animal model.

<sup>265</sup> Dr Smith – Day 59, page 117

medium and account would have to be taken of other elements used to protect Factor VIII in the pasteurisation process.<sup>266</sup> Dr Foster shared this view indicating that the statement on the molecular damage caused by pasteurisation was a 'bit of a generalisation' and that it failed to take account of the amount of heat applied or the use of stabilisers in the pasteurisation process.<sup>267</sup> Similarly, Dr Cuthbertson indicated that the reference to 'heating at 75°C for ten hours or heating at 60°C for 24 hours' was too simplistic noting that 'it's not simply a question of heat and time, it's a question of the stabilisers, the format that the product is in and a whole range of other complex things that lead to the level of inactivation that you finally get'.<sup>268</sup>

### Scottish developments

**23.139** Returning to Scotland, on 23 August 1983, Dr Foster updated Dr Smith on the progress of the pilot-scale pasteurisation programme for Factor VIII and explained that, since Factor VIII survived 'fairly well' for up to one hour at 70°C, an amended regime of 9.25 hours heating at 60°C followed by 0.75 hours at 70°C would be followed in the next trials.<sup>269</sup> According to Dr Foster, Dr Smith visited the PFC on 8 September and 2 November 1983 to discuss coagulation factor research and development and the heat treatment of coagulation factor concentrates.<sup>270</sup>

**23.140** Research into heat treatment continued at the PFC during the second half of 1983. Progress at the end of the year was summarised as part of a more general report by Dr Foster entitled *Progress Report on Studies to Improve Yield and Quality of FVIII Concentrate* dated 20 December 1983. As regards pasteurisation, the report explained that:

Extensive studies have been carried out on the stability of FVIII:C and a range of model viruses to heating in solution in the presence of sorbitol and glycine.

Compared to an albumin control ... the sugar solutions ... showed substantial stabilisation of virus (vaccinia and mumps). Improved heating conditions have been identified to achieve further viral inactivation ....

Even more severe heating results in substantial loss of FVIII activity and the improved conditions are probably the best that can be achieved without an unacceptable loss of yield.<sup>271</sup>

**23.141** The report also indicated that the PFC was carrying out experiments in dry heating, using the same model viruses. Dr Cuthbertson indicated in his witness statement that he carried out the dry heating experiments together with Dr Pepper on 21 November 1983. He described the work:

Vials were either left unheated as controls or were heat treated at 60 or 70°C. The vials heated at 70°C were completely insoluble, so it was not possible to assess the extent of viral inactivation. The vials heated at 60°C were tested and showed a modest degree of inactivation of vaccinia virus, which was significantly less than that found in our pasteurisation studies.<sup>272</sup>

<sup>272</sup> Dr Cuthbertson's statement on viral inactivation to 1985 [PEN.013.0025] at 0036; see also Dr Foster – Day 42, page 38

The report commented that 'initial results suggest that the viral kill is less than that achieved by heating in sugar solutions at 60°C for 10hrs'.<sup>273</sup>

**23.142** Dr Cuthbertson was asked by the Inquiry to provide further information and documentation describing these experiments.<sup>274</sup> He duly provided his handwritten summary of the experiments<sup>275</sup> together with a typewritten copy for ease of reading.<sup>276</sup> In his oral evidence, Dr Cuthbertson explained that the purpose of the experiments was to see whether dry heating would give equivalent inactivation to what the PFC was seeing in the liquid process. It was a kind of control. The temperatures applied, 60°C and 70°C, were chosen because they were the temperatures used for the pasteurised product.<sup>277</sup> Dr Cuthbertson also explained in more detail the difference in viral inactivation between the dry-heated and wet-heated products, noting that in the dry-heated product heating led to 'a 3 log reduction, whereas in the ... liquid product, we were looking at an 8 log reduction' and adding, in reference to the dry-heated product, that:

Just to put that into perspective, an 8 log reduction means 100 million viruses per inoculum being inactivated, whereas this shows about 10,000 viruses per 0.1 ml being inactivated. So the difference in them, because it is a logarithmic scale, is enormous. So it was a much less effective virus inactivation process than the liquid process that we were studying and for that reason we kept going with the liquid process at that time.<sup>278</sup>

**1984**

**23.143** On 5 January 1984, Dr Smith sent Dr Foster a memorandum outlining details of the results of the PFL's experiments on the dry heat treatment of Factor VIII.<sup>279</sup> The memorandum commented on the impact of different heating conditions on solubility and Factor VIII activity and indicated that the experiments showed 'the promising preservation of factor VIII:C<sup>280</sup> and solubility of one batch'.<sup>281</sup> The Inquiry asked whether what was disclosed in this memorandum was new and what effect, if any, this news had on those working at the PFC.<sup>282</sup> Dr Foster's response in his written statement was that:

The memorandum from Dr Smith to myself, of 5<sup>th</sup> January 1984 ... concerned the ability of the current BPL Factor VIII concentrate to withstand dry heat treatment under different conditions. Although these data were more extensive than those that had been obtained by the SNBTS, the results were consistent with those of Dr Cuthbertson and Dr Pepper and were not regarded as representing new findings.

The absence of any data from BPL concerning the inactivation of any viral markers, meant that the data from Dr Smith were of limited value. Virus inactivation data were available for pasteurisation, from laboratory studies with marker viruses by the SNBTS, as well as studies in animals and in patients by Behring, all pointing to pasteurisation being more likely to succeed in making

coagulation factor concentrates safe with respect to non-A, non-B hepatitis than dry-heat treatment. Consequently the information from Dr Smith did not alter the opinion in Scotland that pasteurisation should continue to be the main focus of research on virus inactivation.<sup>283</sup>

**23.144** Dr Smith indicated that:

There does appear to be some gap in technical correspondence, but Dr Foster and I both understood perfectly well that we were pursuing different approaches in the short term, for our respective pressing reasons. For example, during this period PFC was greatly preoccupied with preparing a pasteurised product for clinical trial. My letter would not be intended in any sense to divert PFC from pasteurisation ... simply to show that the Oxford and larger-scale Elstree products were capable of withstanding heat treatment, as Rubinstein predicted. I had no information (and at the time little hope) that this treatment would inactivate NANBH, which remained the goal of pasteurisation.<sup>284</sup>

**23.145** Thus, on Dr Smith's approach, the information in his memorandum did not indicate that the BPL results suggested that the procedure reported would inactivate NANB Hepatitis, and only alerted the PFC to the fact that the BPL's Factor VIII could survive certain forms of dry heat treatment.

**23.146** On 11 January 1984, Professor Ludlam wrote to Professor Cash reporting that the clinical trial of the PFC's pasteurised Factor VIII (batch NY 761) had led to an adverse reaction in one patient:

I write to let you know the outcome of infusing the heat treated factor VIII. The above batch of material was given to a single severe haemophiliac on three separate occasions ....

Infusions were accompanied by reactions on all three occasions. On the first the recipient had a short episode of diarrhoea beginning an hour after the infusion. On the second and third occasion he felt ill towards the end of each infusion. He developed transient central chest pain, pallor and [retching]. There was no change in his pulse, BP or temperature. To ascertain whether this was likely to be an organic reaction to the concentrate we gave him a 'placebo' infusion of ordinary SNBTS factor VIII. He was told that it was the heated material and the infusion protocol was identical. He had no adverse reaction to this standard product.<sup>285</sup>

**23.147** Professor Ludlam therefore concluded that that batch of material 'genuinely gave rise to significant and unacceptably adverse reactions in the recipient'.

**23.148** Professor Cash replied on 16 January 1984 agreeing with Professor Ludlam's conclusions, and expressing the hope that a further batch, with improvements in heat treatment and lower sorbitol content, would be available in April.<sup>286</sup> On 25 January 1984, Dr Gillon wrote to Dr Boulton expressing the view that sorbitol was unlikely to be the cause of the adverse reaction.<sup>287</sup>

---

<sup>283</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1468–69

<sup>284</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1562

<sup>285</sup> Professor Ludlam's letter to Professor Cash [SNB.001.5311]

<sup>286</sup> Professor Cash's reply to Professor Ludlam [SNB.006.4695]

<sup>287</sup> Dr Gillon's letter to Dr Boulton [SNB.007.4127]

**23.149** The information regarding the possibly adverse outcome of the clinical trial had already been intimated at the meeting of the Haemophilia and Blood Transfusion Working Group on 14 November 1983. During this meeting Professor Ludlam appears to have mentioned that the patient experienced, 'minor adverse reactions', possibly implying that the severity of the reactions was less than the 'significant and unacceptable reactions' outlined in the letter of 11 January 1984.<sup>288</sup>

**23.150** The Inquiry asked witnesses for an explanation of the difference in the description of the adverse reaction in the letter of 11 January and the memo of 14 November 1983.<sup>289</sup> Professor Ludlam's response in his written statement was as follows:<sup>290</sup>

At the meeting of the Haemophilia Directors with SNBTS at SHHD on 14<sup>th</sup> November the Minutes record that I reported that there had been 'minor adverse reactions on each occasion' when the heated product was infused. This was how the Minute-taker recorded what he thought had been said and may not have accurately recorded what had actually been stated. I have no recollection of exactly what I said. I might have indicated that the reactions were 'minor' but this does not make them acceptable. A 'major' reaction would have been an anaphylactic one in which there is severe hypotension and is immediately life-threatening – this occasionally is seen with infusion of blood products especially cryoprecipitate.

Further details of the infusions and the reactions are given in my letter of 11<sup>th</sup> January 1984 in which I recorded that 'Infusions were accompanied by reactions on all three occasions ....' The reaction to each infusion was sufficiently marked that an injection of piriton (antihistamine commonly given to reduce 'allergic' reactions) was given on each occasion ....

**23.151** Dr Cuthbertson's view in his written statement was that the reaction was probably not severe, but was not one which would be considered acceptable. He noted that Professor Forbes agreed to trial the product with additional patients, which was not consistent with a severe reaction.<sup>291</sup> However, a later letter from Dr Foster to Professor Ludlam dated 10 February 1984 indicated that Professor Ludlam was the only clinician who had been given an 'inferior batch' to test, the implication being that this could have been the reason for the adverse reaction.<sup>292</sup> Therefore, according to Professor Ludlam the description of the adverse reaction as 'minor' during the meeting of the Haemophilia and Blood Transfusion Working Group on 14 November 1983, may have been due to an inaccurate recording by the minute taker, or may have been accurate and consistent with the letter of 11 January 1984. According to him, the fact that he was prepared to arrange a control experiment with unheated product was evidence that the reactions were 'clinically significant'.<sup>293</sup>

**23.152** On 12 January 1984 the Factor VIII Study Group met.<sup>294</sup> Dr Cuthbertson presented the results of the PFC's research into the viral inactivation of Factor VIII (including the results of viral inactivation experiments using model viruses) and referred to the BPL's work on dry heat treatment and the fact that this work suggested that, 'there is no yield penalty

<sup>292</sup> Dr Foster's letter to Professor Ludlam [SNB.007.4147]

<sup>293</sup> For similar arguments to Professor Ludlam's see Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1771

<sup>294</sup> Minutes of Factor VIII Study Group, 12 January 1984 [SNB.007.4059]

for dried FVIII if it is heated to 60°C for 3 days'. As indicated above, mention was also made of the fact that Hyland's heat-treated product was infective.

**23.153** The Inquiry asked witnesses whether the information on the failure of Hyland product had an impact on the perceived significance of the BPL's progress in dry heating Factor VIII and whether there was any suggestion within the PFC of changing to dry heat treatment at this time.<sup>295</sup> Dr Foster's response in his written statement<sup>296</sup> was that the failure of the Hyland product was indeed considered to be evidence against dry heat treatment, as were the disappointing levels of viral inactivation which Dr Cuthbertson and Dr Pepper had found when carrying out their own dry heat experiments in November of 1983.<sup>297</sup> Dr Foster also pointed out that the fact that the BPL's dry heat treatment experiments lacked any measurement of viral kill was a factor in the PFC's decision to continue with its prioritisation of pasteurisation.<sup>298</sup> Dr Perry's answer was to the same effect. He emphasised that there was no information available worldwide to suggest that heat treatment of freeze-dried product at 60°C would be capable of inactivating an AIDS virus.<sup>299</sup>

**23.154** Dr Cuthbertson agreed with this view, noting that the failure of the dry heat-treated Hyland product to inactivate NANB Hepatitis 'made this process look less promising, whereas the virus inactivation data on the SNBTS pasteurised product were very promising indeed' and that for this reason, it was concluded that the PFC should continue with pasteurisation as the primary heat treatment process.<sup>300</sup>

**23.155** At this time the firm focus of the PFC was, therefore, on continuing its research into the pasteurisation of Factor VIII. Work in this regard continued in the early part of 1984. Events of note included:

- Further clinical trials of heat-treated Factor VIII and the conclusion of a successful trial (with no adverse reactions) by Professor Forbes of Glasgow Royal Infirmary by March 1984.<sup>301</sup>
- The availability for formal clinical trial of a pilot batch of pasteurised Factor VIII at the end of April 1984.<sup>302</sup>
- Further collaboration between Dr Foster and Dr Smith in May of 1984.<sup>303</sup>

**23.156** At this point the target date for the introduction of pasteurised Factor VIII for clinical use was April 1985.<sup>304</sup> That target date was described by Dr Foster in his written evidence as 'extremely ambitious for the installation and commissioning of such a large and complex manufacturing process' adding that this is why 'the focus shifted in August 1984 to the incorporation of Dr Johnson's purification procedure in order to substantially reduce the volume of solution to be pasteurised ...'.<sup>305</sup>

<sup>305</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1469–70. For an additional statement indicating that the PFC April 1985 goal was ambitious, see Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1563. See also Dr Cuthbertson's statement on the same topic [PEN.013.0025] at 0037 for the argument that the proposed timescale was sensible given the number of safety and quality control steps which were needed before issuing a product to patients.

**23.157** The PFC's research into, and focus on, the pasteurisation of Factor VIII continued during the summer of 1984. The collaboration with Dr Johnson of New York University on the development of a high purity Factor VIII product, which it was hoped would allow for pasteurisation in one litre bottles, had stalled due to the delay in applying for a patent and the University's concerns that details of the procedure should not be disclosed before an application was filed.<sup>306</sup> However, on 14 June 1984, Dr Foster met with Dr Johnson in New York and an agreement was made that details of the procedure should be disclosed to the PFC prior to the patent being filed.<sup>307</sup> This agreement paved the way for further work to be carried out at the PFC into the development of a high purity Factor VIII product. Such work included an evaluation by Dr Foster of Dr Johnson's proposed ion-exchange<sup>308</sup> reagent and the setting up of a meeting between Dr Johnson and Dr John Curling of the pharmaceutical company Pharmacia at the ISBT Congress in Munich to look at alternative reagents. The alternative reagent chosen, Q-Sepharose, was delivered to the PFC on 22 August 1984.<sup>309</sup> According to Dr Foster, it was found to be 'very promising', although 'it became clear that further work would be required to fine-tune the chromatography process before it could be integrated into the pasteurisation process'.<sup>310</sup> Due to the additional scientific input needed, Dr Ronald McIntosh was moved from his work on immunoglobulins to take the lead on the high purity project.<sup>311</sup> As indicated above, one of the main aims behind this project was to reduce the volume of solution to be pasteurised, and so facilitate the change from experimental to commercial production.

**23.158** Arrangements for clinical trials of pasteurised Factor VIII were progressing and in June 1984 Professor Cash prepared a report on the activities of the Factor VIII Study Group which contained a separate report outlining 'Preliminary Clinical Evaluation Studies' for heat-treated Factor VIII.<sup>312</sup> The annex explained that:

Preliminary *in vivo* and *in vitro* studies (carried out in Edinburgh and Glasgow), using a 60°C for 10 hours heating procedure demonstrated that the sugar appeared to prevent denaturation of factor VIII. The proposed new studies will be performed using product exposed to the optimal heat treatment (includes a period at 70°C) and are designed to assess biological acceptability, clinical efficacy and residual infectivity.

It is proposed that all heat-treated product made available for patient use until further notice will be issued exclusively for these clinical evaluation studies.<sup>313</sup>

**23.159** The separate report also contained a detailed plan/protocol as to how such studies should be structured as regards assessment of biological acceptability, clinical efficacy and residual infectivity.

<sup>306</sup> Using the chromatographic purification process first discussed between Dr Johnson and Dr Foster on June 27 1983 at a World Federation of Haemophilia meeting in Stockholm. See paragraphs 23.130 to 23.131 above.

<sup>308</sup> Ion-exchange is a process used to separate or purify proteins where selected proteins are bound to a solid matrix and then removed.

<sup>309</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1463

<sup>310</sup> Ibid

<sup>311</sup> Ibid

<sup>312</sup> Report on the activities of the Factor VIII Study Group [SNB.007.4169]

<sup>313</sup> Preliminary Clinical Evaluation Studies report [SNB.007.4407] at 4408

**23.160** On 26 June 1984, Professor Cash wrote to Dr Perry outlining the process for the future issue of the product for clinical evaluation. The letter indicated that this was to be on a named patient basis.<sup>314</sup>

**23.161** On 25–26 June 1984, Dr Smith and other members of staff from the PFL and the BPL visited the PFC to observe the preparation of a pilot-scale batch of SNBTS pasteurised Factor VIII concentrate and took photographs of the process.<sup>315</sup> Dr Foster indicated in his written statement that this was evidence of continuing interest by the BPL and the PFL in pasteurisation in the summer of 1984.<sup>316</sup> Dr Smith confirmed this during his oral evidence. It was suggested to him that progress with dry heat treatment in England was still taking place against the backdrop of a preference, at least in theory, for pasteurisation, as offering a more efficient form of heat treatment. He said:

Very definitely. We were quite near achieving what looked like success in recovering Factor IX from pasteurisation and on Factor VIII we were still working well into the early summer of 1984 on pasteurisation. I think that's the point at which Lowell Winkelman and I went up to [PFC] to see their scaled-up pasteurisation process, and I think even to take photographs.<sup>317</sup>

**23.162** An abstract outlining the PFC's proposed pasteurisation process for Factor VIII (heated at 60°C for 9.5 hours followed by 70°C for 0.5 hours with glycine/sorbitol stabilisers) was drawn up for the 18th Congress of the International Society of Blood Transfusion held in Munich between 22 and 27 July 1984.<sup>318</sup> The abstract also noted that:

A FIX concentrate has been pasteurised in a similar manner giving about 60% recovery of clotting activity over the heating step with no increase in thrombogenicity ....<sup>319</sup>

**23.163** After the summer of 1984, the focus of the PFC's heat treatment programme remained on the pasteurisation of Factor VIII and its clinical evaluation. Dr Foster commented on progress:

During 1983/84, a total of seven pilot batches of pasteurised Factor VIII concentrate (ZHT) were prepared at the PFC for clinical evaluation with the final batch (batch number ZHT-007) being processed on 24/25 September 1984.<sup>320</sup>

**23.164** Thus, by the autumn of 1984 the PFC remained committed to the introduction of a pasteurised Factor VIII product and was actively working towards the introduction of such a product. However, significant developments occurred towards the end of 1984 which, together, would have a crucial impact on the PFC's existing viral inactivation strategy.

<sup>314</sup> Professor Cash's letter to Dr Perry [SNB.007.4447]. <sup>320</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1464

**23.165** On 1 September 1984, Dr Rachanee Cheingsong-Popov, Professor Robin Weiss, Professor Richard Tedder and others published the results of a major study of the prevalence of antibodies to HTLV-III in UK subjects.<sup>321</sup> Haemophilia clinicians responded to the information that an assay for HTLV-III/HIV antibodies was available by submitting samples from their own patients for testing. By the end of October, there was growing awareness among haemophilia clinicians in the UK generally that HIV infection could be contracted from Factor VIII and that transmission could be associated with domestic as well as imported products.<sup>322</sup> Professor Ludlam submitted samples to Professor Tedder. Independently, Professor Forbes submitted samples from west of Scotland patients to Dr Gallo's laboratory in the USA.

### The Edinburgh Cohort

**23.166** It is not known when SNBTS scientists received information about the west of Scotland results. Information about the results in Professor Ludlam's patients was received first, probably at the end of October 1984. A group of patients treated with standard production PFC Factor VIII at the RIE over the period March to May 1984 (ie the so-called 'Edinburgh cohort') had become infected with HIV.<sup>323</sup> Various witnesses were asked when exactly this information was passed on to the PFC, as this was not clear from the documentation available to the Inquiry.

**23.167** The SNBTS had the information over the weekend 26 to 29 October 1984. Professor Ludlam told Dr McClelland on the evening of 26 October.<sup>324</sup> There had been a meeting of the PFC Heads of Department on the morning of 26 October.<sup>325</sup> Dr Perry thought that he could not have known that the patients had seroconverted, or potentially seroconverted before 26 October.<sup>326</sup> Dr Cuthbertson remembered Dr McClelland telephoning him with the news. He remembered a review of all of the available information a week later.<sup>327</sup> Dr Foster first learned of the infections in late October 1984, when Dr Cuthbertson received a telephone call about it. He had thought he had overheard a conversation between Dr McClelland and Dr Cuthbertson.<sup>328</sup> But he thought later that it may have been Dr Boulton who passed on the news to the PFC, explaining that he now knew that Dr McClelland had been ill.<sup>329</sup> The precise date on which the PFC got to know of the events cannot be specified. But it must have been around the weekend beginning 26 October.

**23.168** The response was fast. In the course of a few weeks, the PFC shelved its pasteurisation programme, experimented with dry heating of Factor VIII, and adopted dry heating for all of its intermediate Factor VIII product. Coinciding with the outbreak of HIV infection in Edinburgh emerging intelligence on the effectiveness of dry heating to kill HIV caused a rapid reassessment of priorities. It was apparent that there was a current problem that had to be dealt with. But, before narrating the events which followed, it is appropriate to take note of the wider research environment at the time.

### Information about heat inactivation of retroviruses

**23.169** In October 1984 a 'haemophilia meeting' took place in Cardiff.<sup>330</sup> Notes of the meeting were received at the PFC on 6 November 1984. During this meeting, Professor Mannucci discussed the European trials of the dry-heated product Hemofil T. As outlined above, the trials demonstrated that the product was infective for NANB Hepatitis and that the attack rate was 70%.<sup>331</sup> However, as far as AIDS was concerned, Professor Mannucci reported that after one year no patients treated with the product had apparently seroconverted.<sup>332</sup> AIDS was still not reported as a major threat to haemophilia patients.

**23.170** On the other hand, it was being suggested that HTLV-III was heat-labile. Prior to the Cardiff meeting, an article published in *The Lancet* on 29 September 1984 reported substantial inactivation, after several hours of dry heat treatment at 68°C, of a murine (ie mouse) retrovirus which had been added to Factor VIII concentrate.<sup>333</sup> Dr Foster indicated in his written statement that he was aware of this publication in *The Lancet* and noted that, 'as the AIDS virus was also known to be a retrovirus ... these data suggested that HIV might be destroyed by dry-heat treatment at 68°C'.<sup>334</sup>

**23.171** This research on the murine retrovirus was later referred to in the USA Centers for Disease Control (CDC) *Morbidity and Mortality Weekly Report (MMWR)* published on 26 October 1984, which indicated that:

A recently published study evaluated the thermostability of murine retroviruses inoculated into factor concentrates, using a cell transformation assay. After 48 hours at 68 C (154.4 F), viral titers dropped from 10<sup>8</sup> to two infectious particles/ml.<sup>335</sup>

**23.172** The *MMWR* report also referred to studies carried out by the CDC, in cooperation with Cutter laboratories (a subsidiary of Bayer) in which 'AIDS virus was added to factor VIII concentrate (virus titer 10<sup>5</sup>) and the factor was lyophilized and heated to 68 C (154.4 F)'. The report concluded with a statement which was later to prove crucial that 'virus was undetectable after 24 hours of heat treatment'.<sup>336</sup> Although the PFC subscribed to the *MMWR*, Dr Foster explained during his oral evidence that the journal 'took a couple of weeks to arrive' and that, therefore, the PFC were not yet aware of this research when information about the outbreak in the Edinburgh Cohort was received.<sup>337</sup>

### Protein Fractionation Centre response to the discovery of infection in the Edinburgh Cohort

**23.173** Dr Foster indicated in his written statement that, upon overhearing the telephone conversation in which Dr Cuthbertson was given news of the HIV infections, he immediately called Dr MacLeod to his office to ask him to identify R&D samples of

<sup>330</sup> The Inquiry has been unable to discover the exact date of this meeting.

Factor VIII concentrate that were already available which could be used for heat treatment experiments.<sup>338</sup> According to Dr Foster, Dr MacLeod responded immediately coming to Dr Foster's office, 'before Dr Cuthbertson had put the phone down'.<sup>339</sup> Dr Foster also indicated that Dr Macleod returned with a list of available samples and that they 'drew up a plan of investigation to obtain as much information as possible on the impact that the various additives might have on the ability of the PFC Factor VIII concentrate (NY) to withstand dry heat treatment at 68°C'.<sup>340</sup> When asked when this plan was drawn up and whether this was on Friday 26 October, Dr Foster responded that:

[I]t seems to me more likely that that was the Monday morning and that it was Dr Boulton who was phoning Dr Cuthbertson on the following Monday and that that then led us to carry out these further heat treatment experiments. And I do have a set of results of some of these experiments, which are dated Tuesday, 30<sup>th</sup>, which would be consistent with that.<sup>341</sup>

**23.174** Dr Foster explained in oral evidence that there were two relevant sets of experiments – the experiments carried out by Dr MacLeod which involved samples prepared with different additives, and also experiments with existing product carried out by Mr McQuillan of the quality control department.<sup>342</sup> According to Dr Foster, it was the results of Mr McQuillan's tests which were available on Tuesday 30 October.<sup>343</sup> Dr Foster indicated that these involved dry heating Factor VIII to 68°C (and also to 60°C)<sup>344</sup> and explained that it is possible that these experiments were discussed on the Friday afternoon (ie following the Heads of Department meeting on the morning of Friday 26 October), in light of the publication by Levy and others in *The Lancet* (see paragraph 23.170 above) that the murine retrovirus could be inactivated at a temperature of 68°C.<sup>345</sup> Dr Foster also noted in his written statement that he had:

[S]pecified that heating at 68°C be included, not only because of the publication by Levy et al. of 29 September, but also because this was the highest temperature to which a Factor VIII concentrate (Koate HT of Cutter/Bayer) had been dry-heat treated, in addition to having obtained regulatory approval in the USA ....<sup>346</sup>

**23.175** Dr Foster commented further in his written statement that the results of the experiments by Mr McQuillan indicated that 'PFC's Factor VIII concentrate (NY) could withstand dry-heat treatment at either 60°C for 24 hours or at 68°C for about 3 hours'.<sup>347</sup> In his oral evidence he explained that these were the first dry heat treatment experiments to have been carried out by the PFC since the experiments of Dr Cuthbertson and Dr Pepper in November 1983.<sup>348</sup>

<sup>348</sup> Dr Foster – Day 42, page 60

**23.176** On Wednesday 31 October, the day after the PFC's dry heating results were available, Dr Foster, Dr Perry and Dr Ronald McIntosh travelled to the Netherlands to attend a Plasma Fractionation Conference held by the transfusion centre in Groningen on 1–2 November 1984.<sup>349</sup> The Groningen meeting proved to be a crucial event as, according to Dr Foster, it was there that the PFC became aware, for the first time,<sup>350</sup> of the findings of the CDC/Cutter, which had been published in the *MMWR* on 26 October 1984, that, 'HIV could be substantially inactivated by dry-heat treatment at 68°C for 1 hour'.<sup>351</sup> These findings were contained in an oral presentation by Dr Jason of the CDC made on 2 November 1984.<sup>352</sup> During the public hearings, Dr Perry characterised the Groningen meeting and the knowledge that HIV had entered the Scottish blood supply as a 'strategy-changing moment', explaining that:

For the first time we had evidence from the Groningen meeting that the product that we were making could be inactivated fairly simply but also, and importantly, there was HIV in the UK and certainly the Scottish, blood supply.<sup>353</sup>

**23.177** The Lindsay Tribunal report comments that the results of the research, showing HIV to be sensitive to heat inactivation, were considered highly significant by the CDC and were widely publicised, both formally and informally. There was not yet any clinical proof of the effectiveness of heat treatment against the HIV virus but there was an immediate recommendation in the USA by MASAC<sup>354</sup> that 'Treaters using coagulation factor concentrate should strongly consider changing to heat treating products with the understanding that protection against AIDS is yet to be proved'.<sup>355</sup> This increased the pressure on the manufacturers, including the BPL, to develop methods of viral inactivation. The Lindsay Tribunal found that there was no general move to the use of heat-treated commercial concentrates until after October 1984.<sup>356</sup>

**23.178** So far as Scotland is concerned, Dr Perry said:

This ten-day period brought together, almost coincidentally, the report to Dr Ludlam and the information that we got for the first time from the Groningen meeting, from the CDC and the Cutter people, who demonstrated for the first time that HIV is fairly heat-sensitive and ... the risk/benefit balance changed overnight. It was dramatic and it was quite clear, moving from a position where everyone was very nervous about introducing heat treatment to a position where the advantages clearly outweighed any of the risks.<sup>357</sup>

**23.179** Dr Foster commented in his written statement that the data from the Groningen meeting were discussed by himself and Drs Perry and McIntosh during their return journey from Groningen to Edinburgh and that they 'agreed to propose to Dr Cash that the SNBTS

<sup>357</sup> Dr Perry – Day 45, pages 110–111

should immediately adopt dry heat treatment at 68°C'.<sup>358</sup> A decision was taken to follow this approach, which Professor Cash characterised in his oral testimony as a very difficult one (both emotionally and on a more practical level):

Q. Do you remember that time, November/December 1984, quite clearly?

A. Yes, I do actually.

Q. Yes.

A At least the panic and alarm and the sweat and the terror and the loneliness of it, when the boys came in and said, 'John, we think we should do this and this and this', and they are all looking at me. It is up to you, you are the medical director, to press the button. And there were two problems: were we going to accept the Groningen view that it was okay, our product was going to be okay? Point 1. The second was, which I think would be refused now: what's the legal position of pulling that product that has already been issued and heating it?<sup>359</sup>

**23.180** As regards the issue of the legal position of rapidly introducing heat-treated product, Professor Cash alluded in his written statement to experiencing a sense of isolation at the time.<sup>360</sup> In an additional written statement on this point, Professor Cash commented that:

Despite a request for SHHD support (through Dr AE Bell, (SHHD)), the responsibility to permit the release of the first PFC heat-treated Factor VIII was not shared by SHHD or CSA officials .... But it was shared by clinical colleagues and, through Dr Perry, informal support was obtained from a senior NIBSC staff member.<sup>361</sup>

**23.181** When asked to comment on this suggestion by Professor Cash, the Scottish Government explained that it had been 'unable to find any documents in which the SNBTS complained of a lack of support, or sought additional support, other than funding', noting however, that 'it would appear from the remaining records that the main contact within SHHD in relation to this issue was Dr Bell, who is no longer alive and therefore cannot be consulted'.<sup>362</sup> The Scottish Government also asserted that in its view, the fact that dry heat treatment was ultimately introduced is evidence that active support and funding was provided to the PFC.<sup>363</sup> When asked about this issue during the public hearings, Dr Perry explained that he did contact Dr Duncan Thomas, who was the Head of Haematology at the National Institute for Biological Standards and Control (NIBSC), but that this was not a formal process and was merely a question of talking him through the PFC's strategy and rationale and establishing the extent to which he thought that the rapid introduction of dry heat treatment was an appropriate thing to do.<sup>364</sup> Dr Perry also appeared to have few concerns over regulatory issues commenting that:

I have to say, as an operational manager in a period of enormous concern but also a belief that we could do something very quickly and very effectively, I

<sup>363</sup> In the light of the evidence already recited, this assertion cannot be accepted as accurate or justified on any objective view.

<sup>364</sup> Dr Perry – Day 45, page 116

think, even with hindsight, the concerns over the regulatory process weren't at the front of my mind.<sup>365</sup>

**23.182** It appears that Professor Cash had a telephone conversation with Dr M E Duncan of the DHSS Medicines Division (then charged with the control of licensing of medical products) in November 1984. Dr Duncan wrote to Professor Cash on 26 November 1984 referring to the telephone conversation and confirming that 'the licensing authority wishes to encourage all companies involved in the production of Factor VIII to use a dry heat process in the course of manufacture' and that 'we are inviting each company to consider this proposal and, hopefully, to make early (abridged) application for a new product licence'.<sup>366</sup> The PFC did not require a licence under the Medicines Act 1968. But it appears that Professor Cash, via Dr Perry, received from Dr Duncan Thomas in the NIBSC, the 'moral support' he wanted.<sup>367</sup>

**23.183** On returning to Scotland, Dr Foster wrote a letter to Professor Cash on 6 November 1984 in which he described the information provided during the Groningen meeting as 'encouraging'.<sup>368</sup> The letter included Dr Foster's notes of the meeting which, as regards inactivation of HTLV-III, contained the following information:<sup>369</sup>

Heat inactivation studies (probably by Cutter)

Starting level of virus  $10^5$  particles/ml (LAV)

Conditions

68° wet heating (German method)

68° dry heating

Comment

Complete inactivation in 4 minutes

< $10^1$  particle/ml after 1 hour, complete inactivation at 24 – 78 hr

**23.184** Dr Foster later confirmed, during his oral evidence, that the figure of 68°C mentioned in his notes for 'wet heating' was incorrect and should read '60°C' as this – not 68°C – was the temperature used in the pasteurisation experiments in question.<sup>370</sup>

**23.185** In his written statement, Dr Foster explained that one of the key attractions of dry heat treatment was that it could be applied to existing stocks of Factor VIII concentrate.<sup>371</sup> In the SNBTS Briefing Paper on the Development of Heat Treatment of Coagulation Factors he said that reasons for choosing this heating protocol (68°C for two hours) were as follows:

68°C was selected by the SNBTS as it was the highest temperature that had been applied to Factor VIII concentrate by any manufacturer and was known to be well tolerated by recipients. Two hours was specified because this was the longest period of heating that samples of the existing SNBTS Factor VIII concentrate (NY) from a range of different production batches could withstand, as well as being double the period that had been reported to substantially inactivate HIV.<sup>372</sup>

<sup>365</sup> Dr Perry – Day 45, page 117

<sup>369</sup> Dr Foster's notes on the Groningen meeting of 1–2 November 1984 [SNB.008.6528] at 6529–30

<sup>370</sup> Dr Foster – Day 42, pages 62–63

<sup>371</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1464

<sup>372</sup> SNBTS Briefing Paper [PEN.013.1309] at 1345

**23.186** The SNBTS Briefing Paper explained in more detail that the rationale for choosing to heat for two hours at 68°C was as follows:<sup>373</sup>

- There was evidence from the USA that this degree of heat treatment could inactivate HIV.
- As about 12 months stock of unheated Factor VIII (NY) was available, heat treatment of this stock meant that heat treated Factor VIII could be supplied from donations that had been collected at an earlier stage of the HIV epidemic, thereby enabling a product to be supplied with a lower theoretical risk than one prepared from donations collected later in the epidemic.
- The product was immediately available for heat treatment, enabling sufficient heat-treated Factor VIII concentrate for all patients to be provided very quickly.
- A stock of heat-treated product was available to re-fill the supply chain and to have available product in reserve for unplanned use, emergencies and other contingencies.
- Waiting for Factor VIII concentrate to be prepared with a revised formulation, to enable the product to tolerate heating for 24 hours, would have delayed the introduction of heat-treated Factor VIII concentrate by about five months, ie the time taken to re-start production, manufacture a fresh batch of Factor VIII concentrate and to then obtain the necessary clinical data concerning efficacy and tolerability.

**23.187** Following the meeting in Groningen, the PFC focused on attempting to dry heat Factor VIII to 68°C. During a meeting of the Heads of Department/Section Managers held on Tuesday 13 November 1984, Dr Perry indicated that:

[A]s a result of the amount of information being publicised through the press on the subject of AIDS, there was an immediate requirement for PFC to render all FVIII free from HTLV III virus .... R&D and QC were setting up experiments for heating FVIII at a higher temperature to kill the HTLV III virus without compromising the quality of this product and it was noted that Dr Foster had already subjected some material to this heating process ....<sup>374</sup>

**23.188** The minutes of the meeting also noted that Dr Foster had advised that he might need access to the pasteurisation cabinet and a freeze drier for the purpose of this exercise.<sup>375</sup> In his written statement he explained that access to the pasteurisation cabinet (normally used for albumin processing) was needed as there was insufficient time to obtain a dry heat treatment oven, noting that:

Specialist ovens for dry-heat treatment ... had to be manufactured to order and could not be obtained for about 6 months. In order to avoid delay, the spray cabinet that was used to pasteurise albumin was utilised to heat vials of freeze dried Factor VIII, pending the purchase and delivery of a specialised oven.<sup>376</sup>

---

<sup>373</sup> SNBTS Briefing Paper [PEN.013.1309] at 1345–46

<sup>374</sup> Minutes of PFC Heads of Department meeting, 13 November 1984 [SNB.010.3475] at 3476

<sup>375</sup> Ibid

<sup>376</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1464. See also Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1777–78

**23.189** Dr Foster added that 'although the spray cabinet was normally operated at 60°C, it had fortuitously been designed to function up to 70°C'.<sup>377</sup> Dr Foster said that the successful operation of the spray cabinet was confirmed in a validation run on 14 November 1984, enabling routine dry heat treatment of Factor VIII to begin on 18 November 1984.<sup>378</sup> It was this spray cabinet which was ultimately used to heat sealed vials of freeze-dried Factor VIII concentrate for two hours at 68°C (see step A18 in Figure 20.2 appended to Chapter 20, *Haemophilia Therapy – The Period up to the Early 1980s*).

**23.190** On 22 November 1984, the PFC sent Dr Boulton (Edinburgh and South East Scotland BTS) four vials of Factor VIII which had been dry-heated for two hours at 68°C.<sup>379</sup> These were supplied so that solubility tests could be carried out before the planned limited release of the batch the following week once it had cleared quality control.

**23.191** A meeting of Haemophilia Directors and representatives of the SNBTS took place on 29 November 1984 to discuss the implications of recent findings of HTLV-III antibodies in Scottish haemophilia patients, measures being taken by the SNBTS to prevent transmission of AIDS by blood products, and media-related matters.<sup>380</sup> During this meeting Dr Perry explained that it would be some time before the PFC's pasteurised product would be available and that 'having regard to the established sensitivity of retroviruses to heat, and corresponding reports of the efficacy of heat treatment at 68°C in countering HTLV III activity' dry heat treatment of Factor VIII at 68°C for two hours had commenced as a short-term measure.<sup>381</sup> The minutes of this meeting also noted that clinical trials of this dry-heated product were already underway. Thus, at this point a formal decision had also been taken in Scotland to dry heat Factor VIII as a short-term solution aimed at preventing transmission of AIDS.

**23.192** The clinical trials referred to were intended to ensure that the product still had Factor VIII activity and that there were no unacceptable side-effects to its use. These tests could be carried out quickly. Trials to assess whether the dry-heated product did prevent HIV/AIDS transmission would have taken much longer.

**23.193** On 6 December 1984, Dr Perry wrote a letter to all the Regional Transfusion Directors (ie in Belfast, Glasgow, Edinburgh, Inverness, Aberdeen and Dundee) which confirmed that the first infusions of dry-heated Factor VIII had been successful, although recovery and half-life data had yet to be received.<sup>382</sup> The letter also noted that arrangements had been made for dispatch of the first batches of dry heat-treated Factor VIII, with expected delivery on 10 or 11 December 1984 and that the initial quantities dispatched would provide approximately one month's supply. It was also indicated that following this initial supply, plans were in hand to supply further quantities of dry-heated product to each RTC equivalent to twice the minimum/maximum stock level so as to enable continuous supply to patients after 10 December (this second phase would start in the latter half of the week beginning 10 December and was expected to be completed before Christmas). It was also pointed out that 'in the New Year, PFC will arrange for non-heated product to be collected from RTCs' – ie a recall of non-heated products would take place in the New Year of 1985 – and that the RTCs should 'make arrangements for this material to be recalled as widely as possible in preparation for this replacement programme'.

<sup>379</sup> Letter from Mr McQuillan to Dr Boulton, dated 22 November 1984 [SNB.007.4592]

<sup>380</sup> Minute of meeting of Haemophilia Directors and SNBTS representatives, 29 November 1984 [SNB.001.5256]

<sup>381</sup> Minute of meeting of Haemophilia Directors and SNBTS representatives, 29 November 1984 [SNB.001.5256] at 5257

<sup>382</sup> Dr Perry's letter to Regional Transfusion Directors [SGH.002.6506]. Shortly thereafter, the recovery and half-life data were found to be acceptable – see message from Dr Boulton to Dr Perry [SNB.007.4656]

**23.194** When asked about this general recall programme during the public hearings, Dr Perry explained that 'it was the intention that all product, right down to the patient's domestic refrigerator at home would be recalled and replaced with heat-treated material'.<sup>383</sup> Dr Perry also explained that the PFC arranged this through the RTCs, with the RTCs making the practical arrangements with the patients:

[T]he instruction would have gone from myself to the regional transfusion centres, who were our regional representatives, and they would have liaised with the haemophilia centres and various other holding points because they were the distribution points ... they held the records of where these products were issued to. Therefore in order to effect an effective recall, you had to recall it via the regional transfusion centre.<sup>384</sup>

However, he added that recall from the patients did not occur in order to carry out the initial heat treatment since the SNBTS had sufficient of its own material for this purpose and also because the patients still needed product to treat unexpected bleeds.<sup>385</sup>

**23.195** Dr Cuthbertson also emphasised that the PFC was not directly responsible for the recall, explaining that Dr Perry wrote to the Regional Transfusion Directors who then transacted the recall from individual haemophilia treatment centres, who in turn requested the return of product from their patients.<sup>386</sup>

**23.196** Professor Ludlam described his practice:

Patients were invited to return the bottles of unheated concentrate they had at home and heat treated concentrate was given in exchange. This change over was complete by the end of December.<sup>387</sup>

**23.197** Following on from Dr Perry's letter of 6 December 1984, a meeting of the Heads of Department/Section Managers took place on 7 December 1984 which also confirmed that the clinical trials in question had been successful and that the product would be distributed to the RTCs in the forthcoming week.<sup>388</sup>

**23.198** On 10 December a meeting took place in Elstree between UKHCDO Reference Centre Directors, blood transfusion colleagues and senior staff from Edinburgh and Elstree.<sup>389</sup> The meeting discussed heat treatment and ultimately recommended the heat treatment of NHS products. Although it is not clear what influence, if any, a negative decision by this meeting might have had on the PFC's existing strategy to dry heat its own product, it is worth noting that the meeting appears to have been a difficult one. According to Professor Ludlam's written statement:

It was not an easy decision to make because of the possible adverse effects of heat treatment on the clotting factors and other proteins in the vials which could have had a range of adverse effects on patients. This was particularly difficult because it was very uncertain how effective the heat treatment would be at inactivating the HTLVIII virus ....<sup>390</sup>

<sup>390</sup> Professor Ludlam's note on long term safety monitoring for transfusion transmitted infections [PEN.012.0351] at 0355

**23.199** In oral evidence, Professor Ludlam explained further that, in practical terms the problem was that 'if we had altered the molecule slightly and 100 per cent [of patients] developed inhibitors, then we would have virtually no effective treatment for haemophilia, apart from FEIBA'<sup>391</sup> adding that 'a decision was nearly made not to heat-treat and it was only because two or three people were quite forceful in their views that the decision was made'.<sup>392</sup>

**23.200** Professor Cash made a similar general point in his written statement, indicating that 'there was great concern among many of the clinicians that any form of heating might be associated with protein denaturation which could have serious consequences for the patients'.<sup>393</sup>

**23.201** Later, on 17 December 1984, Professor Cash wrote to the Scottish Haemophilia Directors informing them that they would be receiving supplies of the first-generation heat-treated Factor VIII within the next day or so and requesting them to monitor clinical efficacy and the development of neo-antigens and to take serum samples to test for HTLV-III antibody.<sup>394</sup> Professor Cash's letter elicited a critical response from Professor Ian Hann of the Royal Hospital for Sick Children at Yorkhill in Glasgow who queried, in a handwritten letter to Professor Cash dated 19 December 1984, whether adequate studies of 'neo-antigen formation, efficacy and other safety issues' had been made and whether the PFC would know in the near future whether heat treatment had been effective.<sup>395</sup> When asked to expand on this letter during the public hearings Professor Hann explained that:

Certainly I was very nervous about this approach. Without going into great detail, one normally does not launch a product or a drug in children with very, very limited information. Especially when there is a risk of neoantigen formation, therefore severe reactions which could be even life-threatening. There could be a significant risk of the development of inhibitors, which is a disaster, making patients not responsive to treatment, et cetera.<sup>396</sup>

**23.202** He added:

As it turned out, everything was okay, but I just wanted to express the fact that (a), it was very impracticable to do what was being asked, (b), it wasn't necessarily covering all the types of checks that I would like to see with regard to the liver function tests, et cetera and (c), that it really ought to have been instituted, and I would have preferred to see a bit more evidence that there were no neoantigens, et cetera, and that there was some evidence of safety rather than, 'Here it is, get on with it'.<sup>397</sup>

**23.203** Therefore, in summary, by the end of 1984 the PFC had taken a strategic about-turn due to the threat of AIDS and (notwithstanding the lack of clear-cut evidence that such a process would be successful) had chosen to dry heat existing Factor VIII for two hours at 68°C and to recall existing unheated product.

<sup>396</sup> Professor Hann – Day 21, page 59

<sup>397</sup> Professor Hann – Day 21, page 59

**23.204** At the time, this strategy was seen as a temporary arrangement and, as outlined elsewhere in this Report, further developments (for example dry heat treatment for 24 hours at 68°C) followed. At the time it was not clear whether the heating protocol had been successful in inactivating HIV. However, a later look-back study discussed by Dr Robert Cuthbert and others reported that two of the first batches of PFC Factor VIII heated in November 1984 at 68°C for two hours had been prepared using a donation which was later found to be infected with HIV. It had not subsequently transmitted HIV.<sup>398</sup> The Inquiry is also not aware of any HIV infections associated with Factor VIII heat-treated using this protocol. Therefore, looking back at this period, the evidence suggests that the heat treatment protocol chosen by the PFC (ie 68°C for two hours) was effective in inactivating HIV. As outlined elsewhere in the Report, it was not, however, effective at inactivating NANB Hepatitis.

### General issues

#### *Why did the Protein Fractionation Centre not switch to dry heat treatment earlier?*

**23.205** As outlined above, up until the autumn of 1984 the PFC planned to pasteurise Factor VIII – initially to deal with the threat of NANB Hepatitis and later to deal with the emerging threat of HIV. In late October/early November 1984 this strategy changed and the PFC switched its efforts to dry heat treatment of Factor VIII, which ultimately proved successful at inactivating HIV. Given that the Edinburgh Cohort became infected with HIV in the spring of 1984, one of the key questions for the Inquiry is whether the PFC should have made this switch at an earlier point in time – for example in January 1984.

**23.206** The Inquiry put this question in the following terms to all of the major witnesses who gave evidence:

In retrospect, the infection of the group of people known as the Edinburgh Cohort would have been prevented if PFC had moved to dry heat treated product at the beginning of 1984. It appears that the equipment necessary to do so was either already installed or already obtained. What are the reasons why this did not take place?<sup>399</sup>

At one level, the question was clearly hypothetical. Confirmation that the cause of AIDS was indeed viral, and was to become known as the Human Immunodeficiency Virus, was not available until April 1984, and the first (experimental) test of possible exposure to the virus was not available until August or September 1984. It was important, however, to avoid limiting the issue by prescribing an over-narrow reference period.

**23.207** The Inquiry also posed a similar question to the expert witness, Professor van Aken.

**23.208** As outlined below, the overwhelming response of the witnesses heard by the Inquiry was that the PFC was correct not to introduce dry heat treatment at the beginning of 1984, and that there were rational reasons for not doing so.

<sup>399</sup> Inquiry's schedule of questions on viral inactivation to 1985 [PEN.012.1531] at 1538–39

## Dr Foster

**23.209** Dr Foster's response to this question in his written statement, with references to paragraphs of the Preliminary Report, was as follows:

a) In my opinion, dry-heat treatment was not introduced by the SNBTS in January 1984 for the following reasons:

- the cause of AIDS was not known (paragraph 8.84),
- the virus responsible for AIDS had not been discovered (paragraph 8.84),
- that the virus responsible for AIDS could be inactivated by heat treatment was not known,
- that the virus responsible for AIDS could be inactivated by dry-heat treatment, under conditions that SNBTS Factor VIII concentrate could withstand, was not known,
- the SNBTS was already preparing pilot batches of a heat treated product (ZHT) for clinical evaluation, similar to a number of other manufacturers,
- no manufacturer in the world had switched from unheated to heat treated Factor VIII concentrate, although some manufacturers were heat treating a small proportion of their Factor VIII,
- it was known that dry-heat treatment had not inactivated agent(s) responsible for non-A, non-B hepatitis (paragraph 11.160),
- there was concern<sup>400</sup> that patients might react adversely to heat treated products ....<sup>401</sup>

**23.210** Dr Foster also made the following additional points in his statement: (i) to the best of his knowledge Scotland was the first country to switch completely to heat-treated Factor VIII and the only country to recall unheated Factor VIII at the end of 1984/start of 1985; (ii) it was not until 26 January 1985 that a peer-reviewed paper was published which reported that HIV was relatively heat-sensitive;<sup>402</sup> (iii) although the BPL issued some batches of dry-heated Factor VIII in early 1985, unheated Factor VIII continued to be issued in England and Wales by the BPL until 1 May 1985.<sup>403</sup>

**23.211** During the public hearings Dr Foster was also asked whether an additional reason for not dry heating at the start of 1984 was the fact that it was not then known that HIV had infected the Scottish blood supply.<sup>404</sup> Dr Foster said:

[I]n January 1984, even if we had known that HIV was in the blood supply, we didn't know how to prevent it and what you are suggesting is based on hindsight.<sup>405</sup>

---

<sup>400</sup> Dr Foster's statement includes a reference to a letter from Professor Cash to Mr Watt, dated 22 April 1983 [SNB.007.3625]

<sup>401</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1475–76

<sup>402</sup> Spire et al, 'Inactivation of lymphadenopathy-associated virus by heat, gamma rays and ultraviolet light', *The Lancet*, 1985; 1:188–189 [SNB.007.4724]

<sup>403</sup> For these and other additional background arguments see Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1476–77

<sup>404</sup> Dr Foster – Day 42, page 77

<sup>405</sup> Dr Foster – Day 42, page 78

**23.212** When asked what the PFC would actually have done in these hypothetical circumstances, Dr Foster explained that:

I am sure we would have sat down and done everything we could have thought of. I doubt we would have done something speculative in terms of some treatment that we had no knowledge would or wouldn't work, which might harm patients.<sup>406</sup>

**23.213** Thus, according to Dr Foster, even if it had been clear at the start of 1984 that HIV had entered the donor pool, given that it was not known then how to inactivate the virus it is unlikely that this knowledge would have led to speculative dry heat treatment.

### Dr Smith

**23.214** Dr Smith's response to this question was as follows:

May I be allowed to speculate, since I was not party to PFC's decision-making but was swimming in the same soup at the time? ....

- Prior to November 1984, there was no reason to believe that dry-heating would succeed in preventing transmission of AIDS, and in fact almost all the early dry-heated (commercial) concentrates caused confirmed transmissions of HIV at later dates. In the wake of Hyland's experience, there was no likelihood that NANBH would be inactivated if dry-heating were applied to PFC's F.VIII at that time.
- I am not sure that, in early 1984, it was generally perceived that AIDS had entered the UK donor population. No test was generally available, validated for application to large populations of donors.
- In about May 1984, three patients in England were given mildly-heated (60°C, 72h) Factor VIII, and by the end of 1984 had contracted neither AIDS nor NANBH. [T]his anecdotal experience had no impact on BPL's policy. If in fact the information was considered significant enough for me to share with SNBTS, I would not have expected it to affect PFC policy.
- At the beginning of 1984, clinical trial of PFC's pilot-scale batches of pasteurised F.VIII was still being considered successful ... and there were detailed plans for scale-up and national issue in a credible time-scale .... There was reason to expect that this pasteurised F.VIII would transmit neither AIDS nor NANBH. For several reasons, it is extremely difficult to envisage running two candidate products full-pelt in a unit with limited resources, so a choice had to be made (England did not have the luxury of choice ... and was perhaps lucky in that – but only with hindsight). It should not be inferred that PFC made the 'wrong' choice at that period, or that PFC was slow to modify its position when the evidence moved on, later in the year.<sup>407</sup>

**23.215** Dr Smith was asked during the public hearing to expand on the second bullet point in his written statement and whether the assessment of risk would have been different if it had been known that HIV had entered the donor population at the start of 1984. Dr Smith responded as follows:

---

<sup>406</sup> Dr Foster – Day 42, page 81

<sup>407</sup> Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1565–66

Q. [I]f it had been known at the start of 1984 that AIDS was in the donor population, the assessment of the risk and the timescale within which some sort of viral inactivation process would be required would have necessarily have been different. Would you agree with that?

A. Yes, and I could be wrong. This is my recollection from the time but it is a long time ago and, generally perceived, is rather loose. But I have said it here, this would be a factor, how you perceived the balance of risk/benefit in going to heat treatment, which was still being perceived by some people as very dangerous.<sup>408</sup>

**23.216** Dr Smith was also asked whether the assumption that HIV had not entered the donor pool at the start of 1984 was realistic:

THE CHAIRMAN: In retrospect, was there not a degree of naivety in treating the donor population as in some way hermetically sealed within the boundaries of the United Kingdom? Didn't people travel in those days?

A. Yes, they did, and already by 1983 the Fletcher and Rizza paper had shown that there was no safety from non-A non-B but there were inhibitions against – AIDS was being seen as, like TB and leprosy and syphilis in previous times, as a kind of dirty disease, and you do not want readily to think that your patients or your donors are in that category. This is just psychopathology. It's not good reasons for it. But when I say 'perceptions', I don't know how many percentage of which groups – treaters, patients, transfusionists – would have subscribed to that view.<sup>409</sup>

### Dr Perry

**23.217** Dr Perry's written statement indicated that it was only with the benefit of hindsight that one could suggest that dry heat treatment could have been implemented earlier and referred to similar arguments to those mentioned above in support.<sup>410</sup> Dr Perry's statement also referred to the following additional arguments which, in his view, supported his position:

- That the PFC studies carried out in late 1983 indicated that dry heat treatment of the PFC's existing Factor VIII product (i.e. the experiments carried out by Dr Pepper and Dr Cuthbertson on 21 November 1983),<sup>411</sup> rendered the product insoluble;
- That the formal regulatory position in the UK and elsewhere was that there was inadequate evidence of any benefit (in terms of virus safety) from dry heat treatment (for either AIDS or Hepatitis) to justify the licensing of commercial dry heat treated products; and
- That, at that time, the modern 'precautionary principle' was less developed compared with today with the result that interventions on blood or plasma product safety required a greater body of scientific evidence to justify their implementation.<sup>412</sup>

---

<sup>408</sup> Dr Smith – Day 59, pages 137–138

<sup>409</sup> Dr Smith – Day 59, page 139

<sup>410</sup> Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1778

<sup>411</sup> Dr Perry – Day 45, page 115. See paragraphs 23.141 to 23.142 above. NB – the protocol used by Drs Pepper and Cuthbertson was 70°C for 72 hours and not 68°C for 24 hours as reported in Dr Perry's written statement.

<sup>412</sup> Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1778. It should be noted that Dr Perry's point regarding the precautionary principle does not accord with his description of the lack of regulatory procedures – see above at paragraph 23.181 and Dr Perry – Day 45, pages 116–117. See also Dr Perry – Day 45, pages 83–84 where Dr Perry makes the argument that today's regulatory procedures are much more stringent than those of the early 1980s.

**23.218** Dr Perry was also asked, during the public hearings, to explain why there appeared to be a belief at the start of 1984 that HIV had not arrived in Scotland (and by implication entered the Scottish blood supply). Dr Perry answered as follows:

[W]e must remember that although HIV is a well-known entity for everybody in this room now, at that time it was a new disease, it wasn't understood, there were still alternative ways to describe the AIDS condition and its causation and so on, and little, if anything, was known about the epidemiology and the extent to which it was travelling around the world .... With hindsight, it could have been clearly proposed or suggested that HIV could indeed be in the UK population. We just hadn't seen any evidence of it.<sup>413</sup>

**23.219** As regards the issue as to whether the PFC's strategy would have been different if it had been aware of HIV infection at the start of 1984 Dr Perry offered the following thoughts:

[M]y best guess is that even if we had had evidence of HIV in the donor population, at that point in time that in itself wouldn't have been sufficient to take what would have been seen at that time as a very dramatic step in terms of potential damage to a Factor VIII product. We might have known that HIV was in the donor population but we would have had no knowledge whatsoever of our ability to inactivate it using heat treatment.<sup>414</sup>

#### Dr Cuthbertson

**23.220** Dr Cuthbertson's written statement also commented that, in his view, 'it is only with the benefit of hindsight that it can be concluded that earlier introduction of heat treatment was a sound option', and that 'more rapid introduction of dry heat treatment was not justified on the basis of knowledge at the time and we could have easily introduced a less safe product with reduced yield which still had the capacity to transmit HIV'.<sup>415</sup> Dr Cuthbertson's arguments mirror those outlined above and also make mention of what Dr Cuthbertson refers to as 'Regulatory constraints' – the understanding that the DHSS did not wish to grant licences to commercial dry heat-treated products at this time due to safety concerns.<sup>416</sup>

#### Professor van Aken

**23.221** Professor van Aken provided the Inquiry with a report in which he reviewed the introduction of dry heat treatment of Factor VIII by the PFC and considered the question whether the PFC could or should have introduced this process at the start of 1984.<sup>417</sup>

**23.222** In his report, Professor van Aken referred to the World Health Organization's 2004 'Guidelines on viral inactivation and removal procedures intended to assure the viral safety of human blood and plasma products'<sup>418</sup> which stipulate that the ability of a process to inactivate/remove viruses should take into account:

---

<sup>413</sup> Dr Perry – Day 45, page 112

<sup>414</sup> Dr Perry – Day 45, page 114

<sup>415</sup> Dr Cuthbertson's statement on viral inactivation to 1985 [PEN.013.0025] at 0043

<sup>416</sup> Ibid

<sup>417</sup> Professor van Aken's statement on the introduction of dry heat treatment of Factor VIII concentrate [PEN.012.1932]

<sup>418</sup> *Guidelines on viral inactivation and removal procedures intended to assure the viral safety of human blood and plasma products*, WHO Technical Report, Series No. 924, Annex 4 2004, [http://www.who.int/bloodproducts/publications/WHO\\_TRS\\_924\\_A4.pdf](http://www.who.int/bloodproducts/publications/WHO_TRS_924_A4.pdf). [Last accessed 23 January 2013]

- the reduction of virus titre achieved;
- for inactivation processes, the rate of inactivation;
- the robustness of the inactivation step in response to changes in process conditions;
- the selectivity of the process for viruses of different classes; and
- validation studies, which need to be well documented.<sup>419</sup>

**23.223** According to Professor van Aken, these requirements meant that the safe introduction of a change in the manufacturing process of plasma products such as Factor VIII required: (i) knowledge about the nature and characteristics of virus(es) to be inactivated; (ii) validation studies and studies in experimental animals, and (iii) yield, manufacturing consistency and integrity of the final product with regard to protein function/structure.<sup>420</sup>

**23.224** As regards the first requirement (knowledge about nature and characteristics of virus(es)) and HIV, Professor van Aken's view was that the first indication of the cause of AIDS did not arise until the publication of Professor Gallo's article in May 1984.<sup>421</sup> Therefore, according to his view, at the start of 1984 there was insufficient knowledge regarding the cause of AIDS and consequently:

[I]f heat treatment for inactivation of HIV [had] been introduced in early or mid 1984 (or earlier) it would not have been based on evidence but rather on speculations about the origin of the virus.<sup>422</sup>

**23.225** When asked during the public hearings why commercial companies appeared to have pushed ahead with dry heat treatment in 1983 before all the necessary information was available, Professor van Aken indicated that the commercial companies had taken a 'pragmatic approach'. He said that commercial companies were able to do so since, unlike public fractionators who were confined to their home country, they operated on a worldwide basis and could, therefore, tailor their approach to different attitudes in different markets. If one country had a particularly stringent approach to the regulation of new products the commercial companies could move to another (less stringent) country.<sup>423</sup> Professor van Aken also pointed out that it was not possible simply to copy the protocols used by commercial companies as the heating conditions were either confidential or patented.<sup>424</sup> In his view, another key difference was the fact that public fractionators were often aiming at a policy of self-sufficiency and were therefore more concerned about the impact of heating on yield than commercial companies.<sup>425</sup> Upon further questioning, Professor van Aken also indicated that the fact that the commercial companies' source plasma may have been of a lower quality than that of public fractionators was likely to have been a factor which made them more likely to use heating protocols even when the evidence was not yet definitive.<sup>426</sup>

<sup>419</sup> Professor van Aken's statement on the introduction of dry heat treatment of Factor VIII concentrate [PEN.012.1932] at 1934–35

<sup>420</sup> Ibid [PEN.012.1932] at 1935–36

<sup>421</sup> Gallo, 'Frequent detection and isolation of cytopathic retroviruses (HTLV-III) from patients with AIDS and at risk of AIDS', *Science*, May 1984; vol. 224 [LIT.001.3769]

<sup>422</sup> Professor van Aken's statement on the introduction of dry heat treatment of Factor VIII concentrate [PEN.012.1932] at 1935

<sup>423</sup> Professor van Aken – Day 47, page 46

<sup>424</sup> Professor van Aken – Day 47, page 47

<sup>425</sup> Ibid, page 47

<sup>426</sup> Ibid, page 51

**23.226** As regards validation studies, Professor van Aken made the point that sufficient HIV virus to allow these studies to take place was only available in mid-1984.<sup>427</sup> Therefore, before this period work had to be done using model viruses, and that would not necessarily have been as accurate as validation using the actual virus.<sup>428</sup>

**23.227** As regards requirement three (yield, manufacturing consistency and integrity of the final product), Professor van Aken explained during the public hearings that the issue was ensuring that the product was still effective after heat treatment and also that it had not been changed in such a way that it might cause harm to patients.<sup>429</sup>

**23.228** On the basis of these arguments, Professor van Aken's conclusion on the question of whether the PFC should have introduced dry heat treatment more quickly was as follows:

The answer to the question 'Should/could PFC have moved more quickly to introduce the dry heating of factor VIII concentrate?' is NO for the following reasons:

- the procedure (the proper conditions) to inactivate blood borne viruses, in particular those present in plasma, by dry heating were not known until the later part of 1984;
- the characteristics of the viruses to be inactivated (HIV and HCV) were not known until the beginning of 1984 (HIV) respectively 1989 (HCV);
- cell lines producing sufficient quantities of HIV and HCV<sup>430</sup> to perform validation studies (virus spiking experiments) in the laboratory were not available until mid 1984;
- methods to improve the yield of factor VIII and to determine that the structure of factor VIII (or other clotting factors) after heating is still intact were not yet available.<sup>431</sup>

***Why did the Protein Fractionation Centre not follow through with the proposed acceleration of pasteurisation in 1983?***

**23.229** As mentioned above, on 3 May 1983 Dr Foster wrote a memorandum suggesting that the PFC's existing pasteurisation programme should be accelerated in order to meet the 'worst case' scenario of having to deal with HIV/AIDS.<sup>432</sup> The Inquiry asked Professor van Aken to comment on the suggestion of taking a decision on the basis of a 'worst case scenario' and asked whether he was aware whether other fractionators were also considering such an approach at the time. Professor van Aken provided a written response to this question in a separate report which was discussed during the public hearing.<sup>433</sup>

**23.230** In his report, Professor van Aken explained that in mid-1983 it was not known if a virus was responsible for AIDS and that Dr Foster's suggestion was, therefore, likely based on a presumption to this effect. Professor van Aken also indicated that in mid-1983 evidence that heat would be an effective means of inactivating the agent which caused

<sup>429</sup> Ibid, page 55

<sup>430</sup> It was only cell lines for HIV which were available in 1984 (ie not for HCV). Professor van Aken corrected this mistake in his oral evidence, Day 47, page 56.

<sup>431</sup> Professor van Aken's statement on the introduction of dry heat treatment of Factor VIII concentrate [PEN.012.1932] at 1937

<sup>432</sup> Dr Foster's memo [SNB.007.3635]

<sup>433</sup> Professor van Aken's statement on the acceleration of the existing pasteurisation programme [PEN.012.1928]

AIDS was also lacking. According to Professor van Aken, it was therefore, 'by no means certain that pasteurisation would be a method to improve the safety of plasma products like factor VIII concentrate'.<sup>434</sup>

**23.231** He also indicated that initial pasteurisation attempts in several laboratories had resulted in low yields and that any pasteurisation programme would have to take this, and the possible impact on self-sufficiency, into account. He also pointed to the possible risk of neo-antigen formation as a second negative effect of any pasteurisation of Factor VIII. This could result in the creation of inhibitors in patients, thus complicating their future treatment. Professor van Aken explained further that these considerations were part of the discussion that took place among fractionators in various different countries and that some chose to carry out heat treatment even though important evidence was not available whereas others, such as the Central Laboratory of the Blood Transfusion Service (CLB) in Amsterdam, did not. In the case of the CLB, his report notes that a decision was made in accordance with recommendations of haemophilia physicians in the Netherlands to restrict the manufacture of Factor VIII so as to have sufficient material for the production of freeze-dried cryoprecipitate (reflecting the view that the risk of virus transmission from small pools of cryoprecipitate would be less than from large plasma pools used to make Factor VIII).<sup>435</sup>

**23.232** Professor van Aken's report concluded as follows:

Acceleration of the pasteurisation program by PFC would most likely have led to a low factor VIII yield and consequently fewer products for haemophilia treatment. To compensate such losses a very large increase in the collection of donor plasma in Scotland would have been necessary. In addition the risk of side effects, such as neoantigen formation by pasteurisation, would have made the treatment of a certain number of haemophilia patients more complicated. This leads me to conclude that although acceleration of the pasteurization program by PFC might have seemed an option in 1983, it is unlikely that (as part of a 'worst case scenario') this would have provided a solution for PFC.<sup>436</sup>

**23.233** When asked during the public hearings to comment on his statement that it was 'by no means certain that pasteurisation would be a method to improve the safety of plasma products like factor VIII concentrate', Professor van Aken explained that he thought that Dr Foster's plan to pasteurise all product was logical, given the amount of time which had already been committed to the project.<sup>437</sup> However, he also indicated that he personally was not convinced that 'this was the way to go,' whilst explaining that this was 'his bias' and that he found it difficult to give a clear or explicit answer given the underlying element of speculation at the time.<sup>438</sup> He also stressed that in the Netherlands the patient organisations were particularly concerned about the potential loss of yield which could be caused by heat treatment and that their preference was for yield/supply over safety.<sup>439</sup>

<sup>434</sup> Ibid [PEN.012.1928] at 1928

<sup>435</sup> Ibid [PEN.012.1928] at 1929. Compare Dr Smith's evidence at paragraph 23.21 above of planning for the BPL at April 1981.

<sup>438</sup> Professor van Aken – Day 47, page 59. See also Page 60 where Professor van Aken admitted that he did not know enough about the pasteurisation developments to be comfortable giving a definitive answer, and pages 60–61 where Professor van Aken indicated that the PFC did more pasteurisation research than the Dutch CLB.

<sup>439</sup> Professor van Aken – Day 47, page 62

**23.234** Thus, in conclusion, Professor van Aken's view was that there were certain difficulties with the proposed plan to accelerate pasteurisation of Factor VIII. However, given the inevitably speculative nature of taking such a decision, and the differing considerations inherent in the decision-making process between the Netherlands and Scotland, he found it difficult to give a clear-cut answer as to whether the PFC's plan to pasteurise was a reasonable one or not.

***Should the Scottish National Blood Transfusion Service have been encouraging clinicians not to let their patients try the commercial heat-treated products?***

**23.235** The Inquiry asked Professor van Aken to give a view on whether the SNBTS should have encouraged clinicians not to let their patients try commercial heat-treated products. In other words, was Professor Cash correct to oppose the introduction of formal clinical trials for commercial heat-treated products as outlined in his letter of 17 December 1982 to Dr Lane?<sup>440</sup>

**23.236** In his written statement Professor van Aken explained that such a set of circumstances would be unlikely to have occurred in the Netherlands as the CLB did not offer opinions about commercial products or encourage clinicians to stop or decrease the use of such products. Instead it provided information on its own products, with the Dutch haemophilia physicians having more of an advisory role. Professor van Aken further explained, in this context, that the Dutch association of physicians treating haemophilia patients agreed in January 1983 on the following advice for haemophilia treatment:

- 1) if possible use cryoprecipitate (notably for newly diagnosed patients and children of less than 4 years);
- 2) if factor VIII concentrate needs to be used, prescribe factor VIII concentrate prepared from plasma of Dutch donors (use commercial concentrates only in case of a severe side effects following the use of Dutch concentrate);
- 3) for the treatment of haemophilia B patients use only factor IX concentrate prepared from plasma of Dutch donors.<sup>441</sup>

**23.237** When asked during the public hearings to comment further on Professor Cash's position as expressed in his letter to Dr Lane, Professor van Aken said that, coming from a small country, he understood Professor Cash's fear that clinical trials of commercial products could reduce the number of patients available for any SNBTS trials.<sup>442</sup> However, he also pointed out that he did not think that it was the role of a fractionator to take this stance, noting that:

[I] always have felt that we have to be very cautious when you were going to direct or try to give directions for what other products, what other commercial products should or should not be used, because you are in a competitive market and in my experience it doesn't work when you are trying, as a manufacturer, to influence. That you have to leave to the government or to physicians treating haemophiliacs, but as a producer that is not your personal

<sup>441</sup> Professor van Aken's statement on the acceleration of the existing pasteurisation programme [PEN.012.1928] at 1929–30. Professor van Aken's statement also notes that there was one blood bank in the Netherlands which had a different policy and which recommended the use of commercial heat-treated products. For further discussion of the situation in the Netherlands at this time see Professor van Aken – Day 47, pages 66–70.

<sup>442</sup> Professor van Aken – Day 47, page 65

responsibility. I interpreted that Dr Cash was director here of the SNBTS. So he was in fact the director of a producing institution. And therefore I would be more restrictive. I would try other ways to do this instead of so openly giving a recommendation how it should be done.<sup>443</sup>

***Should commercial heat-treated products (Hemofil T) have been adopted in advance of locally produced products?***

**23.238** As outlined above, the commercial heat-treated product Hemofil T (dry heat for 72 hours at 60°C), which was licensed in the USA by the US Food and Drug Administration (FDA) in March 1983,<sup>444</sup> was later found not to have led to HIV seroconversions. The product was not granted a licence in the UK until February 1985.<sup>445</sup>

**23.239** The Inquiry asked Professor van Aken whether, in his view, Hemofil T should have been adopted in the UK in advance of locally produced heat-treated products. There are two aspects to the question: whether the product should have been granted a licence earlier, and whether it should have been prescribed on a named patient basis. Professor van Aken discussed the first of these.

**23.240** He explained in his report that Hemofil T was later found to transmit NANB Hepatitis (the outcome of Professor Mannucci's 1985 study mentioned above). According to Professor van Aken, looking back, this was one reason to justify the lack of a licence since:

If the marketing efforts of commercial companies such as Hyland would have led to introduce such a product for haemophilia treatment in the UK it would subsequently have created uncertainty and critique when it was shown that the claim of non-transmission of NANB hepatitis proved to be unjustified.<sup>446</sup>

**23.241** Professor van Aken explained that his view was that the adoption of heat-treated products was justified when it could be established that the agent responsible for AIDS was inactivated by the heating procedure. In his view, since the safety of commercial plasma as source material for the manufacturing of Factor VIII was questionable, 'it was prudent not to introduce commercial factor VIII concentrate until it was shown that such products were safe'.<sup>447</sup> Professor van Aken also argued that alternative products such as cryoprecipitate were available which, because they were prepared from small pools of plasma from non-remunerated donors, were less risky than Factor VIII concentrates prepared from very large pools of remunerated donors.

**23.242** Given the above arguments, Professor van Aken concluded that:

[T]he adoption of commercial heat treated products in the UK in advance of locally produced products would have been justified once there was sufficient and reliable data from clinical studies demonstrating the safety and efficacy of such commercial products. *Hemofil-T* did not meet such criteria.<sup>448</sup>

<sup>447</sup> Ibid [PEN.012.1928] at 1930

<sup>448</sup> [PEN.012.1928] at 1930–31

**23.243** The issue of the safety, or otherwise, of Hemofil T as regards HIV was also discussed with Dr Foster during the Inquiry's public hearings.<sup>449</sup> Dr Foster referred to a report which he had drawn up for the Archer Inquiry<sup>450</sup> entitled, 'Response to Questions raised at the Inquiry in Contaminated Blood and Blood Plasma Products'.<sup>451</sup> The report explained, amongst other things, that:

- (i) it was known in September 1983 that Hemofil T had transmitted NANB Hepatitis;
- (ii) the UK Committee on the Safety of Medicines had rejected a licence application for Hemofil T in September 1983;
- (iii) it was not until February 1985 that reports became available that 18 patients treated exclusively with Hemofil T were HIV-negative (according to Dr Foster, although these results were encouraging they did not prove that HIV had been inactivated as there was no evidence that the batches in question were infected);
- (iv) a January 1986 study on the inactivation of viruses in Factor VIII did not contain any data on Hemofil T.<sup>452</sup> According to Dr Foster, to suggest, as had been suggested at the Archer Inquiry, that it was known in May 1983 that the HIV virus could be inactivated by a particular heat treatment protocol, such as that used for Hemofil T, reflected a misunderstanding.<sup>453</sup>

***Did Mr Watt's resignation have an impact on the heat treatment programme?***

**23.244** As outlined above, Mr Watt, the Director of the PFC, decided to leave the PFC in the summer of 1983. This decision was officially communicated to Professor Cash by letter dated 4 July 1983 in which Mr Watt outlined the reasons for his resignation. The reasons included personal matters (including increased domestic commitments and medical issues), as well as a desire on the part of Mr Watt to finish his career as a consultant working in the field of fractionation in a role outwith the PFC.<sup>454</sup> Professor Cash subsequently drew up a confidential document entitled 'Replacement of the Director of PFC (Preliminary Notes)', dated August 1983.<sup>455</sup> In this document, Professor Cash discussed certain problem areas which, in his view, had arisen during Mr Watt's management of the PFC (in particular the lack of management control which the National Medical Director had over the Director of the PFC) and suggested possible solutions. From the tone and content of this confidential report, it is clear that Professor Cash viewed the relationship between himself and Mr Watt as not being in good repair. Although the original plan was that Mr Watt would leave at the end of March 1984, it is evident from a memo from Dr Perry to the Heads of Department and Section Managers dated 30 December 1983 that Mr Watt actually left at the end of December 1983<sup>456</sup> with Dr Perry taking over as Acting Director.<sup>457</sup>

<sup>456</sup> Dr Perry's memorandum of 30 December 1983 [SNB.009.4290]

<sup>457</sup> See letter from Professor Cash to Mr Mutch (Secretary CSA) dated 23 May 1984 confirming that Dr Perry was Acting Director of the PFC [SNB.011.1688]

**23.245** The Inquiry asked various witnesses for more details on the impact of Mr Watt's departure and, more importantly, whether his departure adversely affected the PFC's viral inactivation programme.<sup>458</sup>

**23.246** In his oral evidence Professor Cash confirmed that he was of the view that Mr Watt's departure did not affect the heat treatment programme. The main reason for this was that 'Peter Foster, the solid rock, was still there, as far as that programme was concerned'.<sup>459</sup> As regards the departure of staff, Professor Cash explained that two staff at a senior technical level ultimately left the PFC to work with Mr Watt's consultancy.<sup>460</sup>

**23.247** Dr Foster stated in his written evidence that he learned on Monday 11 July 1983 on his return from Stockholm that Mr Watt had resigned. He was informed by a colleague that Mr Watt was planning to establish a company to fractionate animal plasma and that he was seeking to recruit staff from the PFC.<sup>461</sup> When asked, Dr Foster informed Professor Cash that he had not been approached by Mr Watt and that, if approached, he had no intention of leaving the PFC. According to Dr Foster:

It was evident to me that Dr Cash was worried that the PFC might be damaged by the loss of key staff. Later, he told me that he had discussed the matter with Mr Watt, who had indicated that he intended to recruit only a small number of staff from the PFC to avoid any damage to the PFC. Nevertheless, I believe that it was concern over the potential loss of key PFC staff that led to Mr Watt leaving at the end of December 1983, rather than at the end of March 1984.<sup>462</sup>

**23.248** In his written statement Dr Foster also expressed the view that Mr Watt's resignation did not adversely affect the virus inactivation programme, stating that:

I do not believe the resignation of Mr Watt adversely affected the virus inactivation programme or influenced the SNBTS strategy. According to his CV,<sup>463</sup> Mr Watt continued to be a member of the Biologicals sub-committee of the Committee on Safety of Medicines until 1986. In March 1984 this committee approved an application from Behring for a licence for its pasteurised Factor VIII and, in July 1984, rejected an application for a licence from Armour for its dry-heat treated Factor VIII. I do not know the advice, if any, that Mr Watt offered at these meetings, but the fact that the SNBTS strategy was consistent with both of these decisions does not suggest that Mr Watt would have encouraged the SNBTS to take a different position if he had remained in post.<sup>464</sup>

**23.249** In oral evidence Dr Foster said that the departure of staff to Mr Watt's consultancy did not impact on the heat treatment programme. A few people at section manager, senior technical level left the PFC to join him when he had established his own business. In particular, a person who managed one of the quality control laboratories and also a person who managed one of the areas in production at a senior technical level joined Mr Watt. But these losses were coped with within normal turnover of staff arrangements.<sup>465</sup>

<sup>462</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1467

<sup>463</sup> Mr Watt's curriculum vitae [PEN.012.1491]

<sup>464</sup> Dr Foster's statement on viral inactivation to 1985 [PEN.012.1438] at 1466

<sup>465</sup> Dr Foster – Day 42, pages 30–31

**23.250** Dr Perry was also of the view that Mr Watt's resignation did not adversely affect the viral inactivation programme, stating that:

Mr Watt resigned in July 1983 and following his earlier than planned departure in December 1983 I was appointed as acting Director of PFC.

It is not possible to meaningfully judge the general impact of his departure but by this time the PFC programme on heat treatment was well advanced and there are no specific instances of delays or failures of the development programme attributable to his departure.<sup>466</sup>

**23.251** In line with Dr Foster, Dr Perry also explained in his oral evidence that, in his view, the departure of two staff to Mr Watt's consultancy did not adversely affect the heat treatment programme, stating that:

[I] don't think there were any, what you might describe as absolutely key individuals, that left taking with them intellectual capability or intellectual property. I think that the programme that had been established prior to Mr Watt's departure carried on, ably led by Dr Foster.<sup>467</sup>

**23.252** Dr Perry also provided background to his appointment as Acting Director of the PFC in January 1984, explaining that Professor Cash asked him informally to take on the role and that this was followed up on a formal basis by the secretary of the CSA, Mr Mutch, with confirmation of the permanent role being made a year later in 1985.<sup>468</sup>

## Discussion and conclusions

**23.253** The transmission, in the spring of 1984 (discovered in the autumn of 1984), of HIV infection to haemophilia patients treated in Scotland at the RIE with PFC Factor VIII concentrate was an event of critical importance for this Inquiry. It had a devastating impact on the lives of the patients involved, and on the lives of their families. Most of the patients infected with HIV had died before the Inquiry was instructed. The circumstances in which the patients came to be infected are discussed in Chapter 10, *Knowledge of the Geographical Spread and Prevalence of HIV/AIDS 2*. As is clear from the evidence that has been analysed in this chapter, discovery of the transmission of HIV was a factor that immediately and significantly impacted on the PFC's research and development and production priorities. And what proved to be an effective response, dry heat treatment of Factor VIII concentrate, was quickly put into effect.

**23.254** The evidence sought from documents, written statements and oral testimonies from witnesses, could not be narrowly specified: in fairness to patient interests and to the manufacturers, it was necessary to explore the background in depth. But there were some obvious questions that provided focus for the investigation and presentation of the evidence:

- Was there a risk of HIV infection in blood donated in Scotland that affected the safety of PFC products?
- When was such a risk was understood to exist?
- Was or should that risk have been taken into account by the SNBTS and the PFC in the processing of blood products?

---

<sup>466</sup> Dr Perry's statement on viral inactivation to 1985 [PEN.012.1759] at 1770

<sup>467</sup> Dr Perry – Day 45, page 61

<sup>468</sup> Dr Perry – Day 45, pages 64 and 67

- More specifically, should the threat of AIDS have caused the PFC to accelerate its heat treatment programme in or around May 1983?
- Was adherence to the pasteurisation programme until October/November 1984 justified? In particular was that course justified after January 1984?
- Was there sufficient liaison/cooperation between the fractionation services in Scotland and England over the period 1980 to 1984 in relation to viral inactivation?
- Did any management problems impact on the PFC's viral inactivation programme?
- Would closer collaboration, and UK-wide policy guidance, have avoided the pursuit of different courses by the Transfusion Services in Scotland and England, and would it have been more effective?
- Did the PFC have sufficient resources/staff and access to information/academic research for its viral inactivation programme?
- Should commercial heat-treated products have been adopted in advance of locally produced products or could/should the PFC have bought in a commercial heat-treated process<sup>469</sup> instead of developing its own?
- In general, was the approach taken to viral inactivation at the PFC in the period 1980 to 1984 reasonable?
- In general, was the degree of priority accorded to viral inactivation by the PFC during this period reasonable?

***The risk of HIV infection in blood donated in Scotland that affected the safety of Protein Fractionation Centre products***

**23.255** As discussed in Chapter 33, *An Investigation into the Systems in Place for Informing the Patients about the Risks – HIV/AIDS*, it was understood within the SNBTS by May 1983 (though not reflected in uniform action throughout Scotland) that certain groups of individuals presented a risk of transmission of the presumed infective agent causing AIDS if they donated blood, and were therefore asked not to present themselves as donors. The advice was based on reports of the US experience rather than on reported cases of transmission in the UK involving any of the groups identified. The aetiology of AIDS, and therefore the precise nature of the risk, was not at that stage well understood. The preparation and issue of leaflets reflected apprehension that there might be a risk rather than knowledge of an existing risk.

**23.256** By late July 1983, the Central Blood Laboratories Authority had concluded that AIDS was likely to include in its aetiology transmission of an infective virus, and noted that this had prompted more activity in the area of blood products pasteurisation.<sup>470</sup> At this stage it was thought that domestic products presented a low risk.<sup>471</sup> The view of the Biological Sub-Committee of the Committee on the Safety of Medicines, who at that stage were opposed to the withdrawal of imported products, was that:

Efforts are ... being made to secure UK independence of foreign suppliers of clotting factor concentrates. This should reduce markedly, although not

---

<sup>469</sup> See Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1573 for a very brief mention of this point.

<sup>470</sup> CBLA paper on AIDS, dated 26 July 1983 [DHF.002.4489] at 4490

<sup>471</sup> Summary of main points from a consideration of AIDS and licensed blood products by CSM(B), 13 July 1983 [DHF.002.8865]

eliminate, the risks to recipients of these products, and the Sub-Committee strongly supports this aim.<sup>472</sup>

**23.257** At that time virus inactivation of Factor VIII and Factor IX products was a 'promising future development', and the assessment of risk was related to the presumed low level of infection in domestic blood donations. As stated in paragraph 8.45 of the Preliminary Report, self-sufficiency was seen as part of the answer to the problem of AIDS. The possibility that the agent of transmission was already present in the UK blood supply had not been specifically acknowledged.

**23.258** The death of a haemophilia patient in England in August 1983 was associated with imported products.<sup>473</sup> A further patient had received English therapy. The products he had received were under investigation, but no link had been established. An article by Dr Peter Jones in the *British Medical Journal*, published on 10 December 1983, noted that two AIDS cases had been reported in haemophilia patients in the UK.<sup>474</sup> At the end of the year there was media comment on the number of AIDS cases.<sup>475</sup> Apprehension that there was a present risk arising from UK products was beginning to appear in some quarters.

**23.259** A meeting arranged by the NIBSC to examine the infectious hazards of blood and blood products, with particular reference to hepatitis and AIDS, was held on 9 February 1984.<sup>476</sup> It was reported that the most recent information indicated that two UK patients and nine other European patients with haemophilia had contracted AIDS. A report by the Centres for Disease Control and Prevention (CDC) had identified 31 recipients of blood transfusion in the USA who had contracted AIDS. Association with UK products was not reported.

**23.260** It was not until the development of tests for anti-HIV and the report of research by Dr Cheingsong-Popov, Professor Weiss, Professor Tedder and others was published on 1 September 1984 that any data on the prevalence of anti-HIV seropositivity among 'at risk' groups in England were available.<sup>477</sup>

**23.261** The period when the SNBTS and the PFC might have acknowledged that the domestic product might be infected with HIV runs from the turn of the year 1983–84 until early September 1984. During that period the risk to haemophilia patients in Scotland was real: the Edinburgh Cohort patients were infected by PFC product.

**23.262** However, on the evidence as a whole, there was no basis on which it could be inferred that an actual present risk was known, or should have been known, to the SNBTS, the PFC, or, indeed, the haemophilia clinicians. They shared, with colleagues in England and Wales, the understanding that there was a potential risk. The second and third questions have to be considered in that context.

<sup>472</sup> Ibid [DHF.002.8865] at 8866

***Steps taken by The Scottish National Blood Transfusion Service/Protein Fractionation Centre to take account of the potential risk of transmission of HIV in the processing of blood products***

**23.263** As the narrative of the evidence shows, the PFC's research relating to virus infection concentrated on hepatitis until early 1983. Then there was the beginning of a subtle change of focus as the possible risks which AIDS might pose to the blood supply began to be understood. From then the scientists realised that research would focus, not exclusively on hepatitis, but also on AIDS. By March 1983 recognition of the importance of AIDS was tentative: explanations of the absence of a formal record of discussion of the subject at the Haemophilia and Blood Transfusion Working Group meeting on 22 March 1983 demonstrate that opinion had not become firm on the relevance of the topic.<sup>478</sup>

**23.264** Dr Foster's memorandum of 3 May 1983 marked the beginning of a substantial shift towards recognising the relevance of the AIDS risk. By the end of the year there had been a substantial programme of research, set out in paragraphs 23.128–23.132 and 23.139–23.142 above. The potential risk was clearly taken into account and influenced the programme of research into the formulation and processing of the PFC's products.<sup>479</sup>

***Should the threat of AIDS have caused the Protein Fractionation Centre to accelerate its heat treatment programme in or around May 1983?***

**23.265** This question was prompted by Dr Foster's memorandum of 3 May 1983. It implies that, in acknowledging the potential risk from AIDS, not only should the direction of research have been altered, but that the progress of that research should have been accelerated. Dr Foster identified the issues clearly. NANB Hepatitis was thought to have infected all severely affected haemophilia patients because of the inherent infectivity of large-pool concentrates. So long as the focus was on hepatitis, strategy could focus on those who had received little treatment, and a proportion only of total production had to be treated for virus inactivation. With AIDS, those who needed most treatment were exposed to the greatest risk of infection. It would not be possible to differentiate, and all production would require to be heat-treated. It was possible that the timetable would require to be reviewed.

**23.266** Mr Watt's letter to Professor Cash dated 5 May 1983 supported the speeding-up of the programme.<sup>480</sup> The initial request sought funding from the budget set aside to cover costs arising from compliance with the Medicines Inspectorate recommendations. Unfortunately, this request was turned down. The subsequent submission for funds was successful. However, it was not until August 1984 that the funding issue was resolved. If the scientists at the PFC had waited until the resolution of that issue, there would have been a very considerable delay in progress.

**23.267** That did not happen. There was progress, and the question whether there should have been acceleration must be considered in the light of the evidence of what happened in fact rather than on the implementation of the specific scheme put to Professor Cash.

**23.268** A batch of pasteurised Factor VIII was sent out for clinical trial on 13 June 1983. There was a review of the research programme on 15 June. By that time, the heating protocol had been developed to specify pasteurisation at 60°C for 10 hours and at 70°C

---

<sup>478</sup> See paragraphs 23.107 and 23.108 above

<sup>479</sup> Dr Foster's memorandum to Mr Watt of 3 May 1983 [SNB.007.3635] referred to in paragraphs 23.109 to 23.111

<sup>480</sup> Mr Watt's letter [SNB.007.3638] at 3640

for half an hour. Tests of virus kill were in place using model viruses, and loss of Factor VIII activity was being monitored. In the light of experience, an amended regime of heating at 60°C for 9.25 hours followed by 0.75 hours at 70°C had been developed for testing in the next round of trials. Dr Foster's report dated 20 December 1983 on progress in the studies to improve yield and quality of Factor VIII concentrates included comment on extensive work on the stability of FVIII:C (activity) and a range of model viruses used in heating in solution in the presence of sorbitol and glycine in conditions which were, in his opinion, probably the best that could be achieved without an unacceptable loss of yield.<sup>481</sup>

**23.269** There is no basis in the evidence on which it could be found that that programme could have been accelerated to any significant extent. On the contrary, the evidence indicates that progress was acceptable.

**23.270** The scientific witnesses were generally in agreement that the funding issue did not affect progress which went ahead according to the development programme. Dr Perry's evidence was that despite the funding issues, the programme was carried out. Dr Foster's evidence illustrates an aspect of the conduct of business at the PFC which was to arise in other contexts. The scientists got on with the work they considered relevant and important, and left questions of administration and funding to others. In their separate views, what did hold up progress of the pasteurisation programme in the latter part of 1983 was the organisation and conduct of clinical trials (in part another administrative issue) and not funding.

**23.271** As narrated in paragraphs 23.155 to 23.156, research and development work was well advanced in the early part of 1984, and an ambitious target for the installation and commissioning of the necessary production facilities had been set. The impression reasonably gained from the evidence as a whole is that the scientists made good progress, conscious of the threat of AIDS as it was understood at the time, and that there is no basis on which they could have accelerated the work.

***Was adherence to the pasteurisation programme until October/November 1984 justified, and in particular was that course justified after January 1984?***

**23.272** By December 1983, Dr Foster was reporting good progress in the pasteurisation of Factor VIII in the presence of sorbitol and glycine. The CBLA report of 26 July 1983 had indicated that pasteurisation was more homogeneous and efficient than dry heating.<sup>482</sup> The adverse comments on pasteurisation in the report were subject to significant criticism by the witnesses who gave evidence to the Inquiry. It is not possible to treat the comments on pasteurisation in the CBLA report as substantial or as likely to be material to a decision whether to persist with pasteurisation in 1983. Until the end of the year there is no reasonable criticism that can be made of the PFC's pursuit of a solution to the problem of virus inactivation that employed 'wet' heating (pasteurisation).

**23.273** In January 1984, Dr Smith sent Dr Foster a memorandum on the PFL's experiments on the dry heat treatment of Factor VIII. Findings reflected in the memorandum were set out in paragraph 11.156 of the Preliminary Report. Written and oral evidence now available to the Inquiry provides a fuller insight into the report and its significance. Dr Smith's evidence (paragraph 23.144) indicates the limited scope of the memorandum, and is in line with

<sup>481</sup> Progress Report on Studies to Improve Yield and Quality of FVIII Concentrate, 20 December 1983 [PEN.012.1500]

<sup>482</sup> CBLA report on AIDS [DHF.002.4489]

Dr Foster's understanding. The two English facilities had demonstrated, at laboratory scale at Oxford and large-scale at Elstree, that the English Factor VIII products could withstand heat treatment, as Rubenstein had predicted at the International Society of Haematology/International Society of Blood Transfusion Congress in Budapest in August 1982. It had not been demonstrated that the treatment applied would inactivate NANB Hepatitis, and Dr Smith at that time had little hope that it would. Dr Foster considered that the results, though more extensive, were consistent with the PFC's own findings on dry heating. His view was that, without evidence of inactivation of any viral markers, the data were of limited value. The SNBTS had data from laboratory studies using model viruses, and published data from Behring, which pointed to the relative effectiveness of pasteurisation in making concentrates safe from transmission of NANB Hepatitis viruses.

**23.274** In the light of this evidence, the PFC was fully justified in pursuing the pasteurisation project undeterred by the information provided by Dr Smith in January 1984.

*Was there sufficient liaison/cooperation between the fractionation services in Scotland and England over the period 1980 to 1984 in relation to viral inactivation? Did any management problems impact on the PFC's viral inactivation programme?*

**23.275** It is not inevitably the case that closer collaboration would have been of advantage to either service. If that had involved restricting the scope of research, the benefit of having two independent, and skilled, teams of investigators could have been lost. The issue is, rather, whether there was sufficient contact and exchange of information to ensure cross-fertilisation of research, giving each team the benefit of the other's work.

**23.276** The Inquiry considered two factors that might have influenced the exchange of information between Scotland and England: firstly, any formal structures providing links between the two transfusion services and their fractionation facilities; and secondly, the nature of personal contacts and communications between staff at the PFC and the BPL.

**23.277** As far as formal links were concerned, the transfusion services in England and Scotland and their associated fractionation facilities reported to different government departments and Ministers. While collaboration in specific research and development projects was arranged from time to time, there were no formal structures in place to ensure communication between the PFC and the BPL/PFL or to coordinate their work generally.<sup>483</sup>

**23.278** Professor Cash maintained that he had been anxious to foster collaboration. In oral evidence, he said:

It has always been my belief that had the two organisations (BPL and PFC) been able to pool their limited R&D resources, and perhaps some manufacturing resources, it may have ... made a significant difference, throughout the 1980s, to the availability of desirable plasma products in the UK.<sup>484</sup>

---

<sup>483</sup> In the 1980s there was collaboration in virus inactivation studies of 8Y, and on the thrombogenicity of heat-treated FIX concentrates, for example, [PEN.013.1309] at 1338–39

<sup>484</sup> Professor Cash – Day 57, page 135; See also Professor Cash's statement on viral inactivation from 1985 to 1987 [PEN.017.1085] at 1089

**23.279** In his view it was in the public interest that there should be formal links.<sup>485</sup> Consistent attempts to try and forge closer relationships between the Scottish and English transfusion services, in different areas, were a constant theme of his tenure as national medical director.<sup>486</sup> He believed that there was a critical shortage of research staff – the background to the comment in paragraph 23.93 about the value of Dr Foster.

**23.280** In a paper for the chairman of the CSA dated January 1984, Professor Cash provided some background information describing the comparative roles of the Central Blood Laboratories Authority (CBLA) and CSA. Having described the position generally, he wrote:

[T]he formal relationships between BPL (originally managed by the Lister Institute) and the SNBTS have not been satisfactory over the years.

**23.281** Professor Cash told the Inquiry that:

[A]t CSA, the Department of Health level, major efforts were made by some well meaning people to get these organisations together at a supramanagement, strategic level; frankly we failed. With the one exception, and that is when DHSS decreed that BPL were to go up to Scotland to get the virus inactivation validation studies done. That was the only occasion.<sup>487</sup>

**23.282** The Inquiry explored whether, in the absence of any other structural links, the CBLA Central Committee on Research and Development in Blood Transfusion, which first met in 1983, might have provided a more formal route for the exchange of information.

**23.283** Professor Cash knew about the Central Committee On Research and Development: it was never going to bridge the gap between the SNBTS and the BPL/PFL because, in his view, it did not enjoy the support of the DHSS or the SHHD.<sup>488</sup> Dr McClelland, who was a member of the committee, 'was under the impression that this was essentially an English committee ... set up to advise the CBLA'.<sup>489</sup>

**23.284** For his part, Dr Perry's recollection was that the committee 'was never recognised as a UK committee and certainly never exercised any formal influence over the activities of the SNBTS – although the SNBTS took account of its actions and recommendations in its own planning processes'.<sup>490</sup> His impression was that the committee's role was 'primarily observational and reactive in relation to ... decisions taken elsewhere'. Dr Foster had not been aware of the Committee and did not believe that PFC representation on it would have led to the earlier introduction of Z8.<sup>491</sup>

**23.285** As far as personal contacts and communications were concerned, the Inquiry heard evidence that the relationship between senior managers at PFC and BPL had sometimes been difficult, whether from personal differences or from disagreements about strategy.<sup>492</sup>

**23.286** In spite of this, and in spite of the absence of formal links between the organisations, there was real and substantial collaboration between them at the level of the scientific officers engaged with research. The close working relationships that existed between scientific staff at the PFC and the BPL have already been discussed at paragraph 23.75 above.

**23.287** For his part, Dr Foster resisted the suggestion that organisational problems affected relationships between the scientific officers. He had no personal experience of difficulties. He said:

[W]henever I met Dr Lane, it was always a very pleasant experience and I have to say I didn't meet him that often and I was always encouraged by Mr Watt to interact with colleagues at BPL and at PFL quite freely, and that was, to my knowledge, always reciprocated and I was never ordered to disengage this liaison at any time. I was aware that Mr Watt and Dr Lane had different views and that's understandable, that they were – at this time people did have different views but Mr Watt was very much trying to take forward the plan that English plasma be processed in Scotland and I don't think Dr Lane saw things the same way. So there was a point there, where they clearly disagreed and that's conceivable that that might have led to some friction but that's really all I can talk to. That's all I'm aware of.

Q. From your position as head of research and development at PFC, how were your relations with your counterpart or counterparts down south?

A They were always excellent ... shortly after I joined PFC, I was given a task by Mr Watt to lead a delegation from PFC to BPL to help people to meet their counterparts, and there were maybe 10 or 12 people from PFC went down to BPL, they met their counterparts, that was reciprocated by visits from BPL, and we always encouraged our staff to communicate with their counterparts and that was always the situation and remained the situation [throughout] my employment.

Q. So there was communication, not only between yourself and Dr Smith but also the staff beneath you as well?

A. Yes, very much so. All of my staff were encouraged to deal with their counterparts because we saw ourselves in the wider sense part of the same organisation. We all worked for the NHS and we were in an area where it's really highly specialised. So to find somebody who is dealing with the same problems and same issues is not something that happens every day. So to have, if you like, another branch of the same organisation where you can talk to somebody was really a very good thing to have. So we did encourage that and I think that happened at BPL as well. And I'm not aware of anybody saying, 'Please stop doing this,' either at BPL or PFC.

**23.288** Dr Foster was asked about Professor Cash's attempts to institute more formal relations. He said:

I can understand why Professor Cash perhaps was seeking something more formal because the relationships that we had were to a large extent informal and it did depend on the individual personalities, and if I had left or Dr Smith

had left and someone else had come [along], things might have been different. So Dr Cash might have wanted something more formal to have a structure in place. So I can understand that but from my perspective it wasn't necessary, but if Dr Cash had said, 'Please do this more formally,' we would have done.

Q. So certainly we saw the use of the words 'formal relationships' in Dr Cash's briefing notes and he did recognise in the notes that there was communication, dialogue and liaison between yourself and Dr Smith.

A. Yes, and if we had been asked to do it more formally then we would have had no difficulty with that.<sup>493</sup>

The exchange provides a clear indication of the approach adopted by Dr Foster to collaboration, as well as illustrating the balanced views he held about relationships in a wider context. There is no basis for apprehension that the apparent inability of senior management to develop formal structural arrangements for the exchange of information had any impact on scientific research and development at this stage.

**23.289** Indeed, Professor Cash accepted, in relation to the development of Z8, that given the relationships between Dr Foster and Dr Smith in particular, there was not a wide gap between the SNBTS and the BPL/PFL.<sup>494</sup> Their personal liaison was the best opportunity for exchange of information in the circumstances.<sup>495</sup>

**23.290** Dr Foster acknowledged that there were two occasions on which the CBLA's interest in the protection of intellectual property rights might have inhibited the exchange of information temporarily.<sup>496</sup> The PFC may have withheld information for similar reasons. Dr Foster said:

I did apply for a patent application for the method of thawing plasma, which I had designed, and that patent was awarded and so it's conceivable that that information wasn't given to BPL immediately but it was published shortly thereafter. The only other example I can think of is when we were working with Dr Johnson and, of course, we had to sign confidentiality arrangements with him and we weren't allowed to discuss that with anyone else.<sup>497</sup>

**23.291** The advice he had received from patent lawyers was that one should not breathe a word about an invention to anyone before filing because of the risk of prior disclosure undermining the application. Dr Smith received similar advice.<sup>498</sup> He commented that proprietary information released under a confidentiality agreement never featured in exchanges between the PFC and the PFL.<sup>499</sup>

**23.292** The UK as a whole, and for present purposes Scotland in particular, were fortunate indeed in benefiting from the relationships among the scientists engaged in their respective research projects in virus inactivation, despite the lack of formal structures. The active collaboration that resulted made good the lack of formal structures and met the needs of this period.

*Would closer collaboration, and UK-wide policy guidance, have avoided the services in Scotland and England pursuing different courses and have been more effective?*

**23.293** Any answer to this question must be speculative to a degree. It is impossible to know how UK policy would have been developed, or how policymakers would have obtained the information required to instruct policy, or how policy would have been formulated. More particularly, since there would inevitably have been competing priorities, it is impossible to know how such issues would have been resolved, or what the outcome would have been. Pooling of knowledge and thought, such as Professor Cash envisaged, might have added intellectual mass to the single project and accelerated progress. Alternatively, if the two services had been compelled to limit their researches to one common approach, the distinctive contributions of each might have been lost. Avoiding the pursuit of different courses would not necessarily, or obviously, have been to the advantage of the UK as a whole or Scotland in particular.

**23.294** So far as the second aspect of the question is concerned, it is possible to be more positive. It was the ability of Scottish scientists to pursue their own research that resulted in the development of effective heat inactivation at the end of 1984, enabling the SNBTS to provide the first comprehensive national supply of heat-treated Factor VIII in the world. At that stage, the Oxford and Elstree facilities were not carrying out model virus studies. Scotland was able to validate the effectiveness of the processes. While it is impossible to say where a fully integrated joint research programme would have reached by this stage, there is no basis in evidence for a view that a UK policy decision directing collaboration between the two services would have resulted in more effective research progress than was achieved in Scotland.

*Did the Protein Fractionation Centre have sufficient resources, including staff, and access to information and academic research for its viral inactivation programme?*

**23.295** Research links with the universities were not explored in detail in oral evidence, since there was no suggestion that there were barriers on the side of the public facilities that prevented access. In the mid-1980s there were close links between the SNBTS and Heriot-Watt University which were referred to in evidence. Professor Charles Brown conducted a research programme in biochemistry. One of his students was Dr Valerie Hornsey. The supervisors of her PhD studies on monoclonal antibodies, completed in 1988, included Dr Prowse and Dr Pepper. Dr Hornsey went on to join the SNBTS. Interaction of this kind with higher education institutions was not, and is not, uncommon in Scotland. However, as noted in Chapter 20 *Haemophilia Therapy – The Period up to the Early 1980s*, at paragraph 20.73, Dr Foster failed in his attempts to encourage research groups at a number of UK universities to undertake fundamental research into ways of eliminating the risk of coagulation factor concentrates transmitting hepatitis. Collaboration requires both parties to be convinced of the value of the research proposed.

**23.296** Whether access to academic research was sufficient might theoretically have been an issue, but it did not arise for extended examination on the evidence available to the Inquiry. Given the published research output of SNBTS scientists, there is good ground for the view that they were themselves at the forefront of academic research. The fact that SNBTS scientists were invited to provide supervision of academic research projects supports that view.

**23.297** Human and other resources are, almost as a matter of tradition, stretched in the public service. Professor Cash would no doubt have been willing at any time to invest more had the funds been made available. Questions were to arise later about resources, in connection with the development of products effectively heated to kill Hepatitis C. So far as this period is concerned, the evidence of Dr Foster and Dr Perry (paragraph 23.125) was that lack of resources did not delay research. Dr Foster's characteristic view was that it was not an issue for him and his research colleagues: it could be left to Mr Watt and Professor Cash to sort out.

**23.298** The answer to the question, at the end of the day, is that the work was done, it was done effectively, and it was done with remarkable expedition. Additional resources would no doubt have been welcome, but lack of resources did not inhibit progress.

*Should commercial heat-treated products have been adopted in advance of locally produced products or could/should the Protein Fractionation Centre have bought in a commercial heat-treated process instead of developing its own?*<sup>500</sup>

**23.299** It is necessary to define a time-frame for this question. Licences for heat-treated factor concentrates began to be issued in the USA in 1983, as set out in paragraphs 23.28 to 23.30 above and Appendix I to this chapter. The products licensed in the USA that have to be considered were:

- Baxter/Hyland's Hemofil T, licensed in March 1983
- Armour's HT Factorate, licensed in January 1984
- Alpha Therapeutic's Profilate HT, licensed in February 1984
- Cutter's Koate HT, licensed in February 1984

**23.300** Commercial heat-treated products were not licensed by the UK Medicines Control Agency for release in the UK until February 1985. Before that date, Scottish Haemophilia Centres purchased and infused heat-treated commercial products on a named patient basis. Assuming that the products used after licensing in the USA were heat-treated, Edinburgh used Factorate in 1984. Glasgow Royal Infirmary used Hemofil in 1984. Yorkhill used Factorate in 1984. None of these regions used any commercial product in 1985 and 1986. Aberdeen, Dundee and Inverness did not use commercial products over the material period. Haemophilia clinicians were not excluded from the commercial market. Indeed in England and Wales commercial purchases accounted for the majority of Factor VIII used at this period. The PFC's first heat-treated Factor VIII concentrate was issued in December 1984.

**23.301** The question can only relate to the general adoption of imported heat-treated products, and necessarily assumes that UK licensing might have occurred earlier than February 1985. There is no basis on the evidence for a finding that the UK licensing process at this time was other than in accordance with normal practice, or unduly delayed.

**23.302** There were other factors in the short period between US licensing and the production of the PFC's heat-treated product. As noted in paragraph 23.28, Behring's product, Haemate P, was available in small quantities from 1980 in Germany and some other places. It was not licensed and was not available in the UK. Initial chimpanzee

---

<sup>500</sup> See Dr Smith's statement on viral inactivation to 1985 [PEN.012.1551] at 1573 for a very brief mention of this point.

studies of Baxter/Hyland's product Hemofil T suggested that it was effective in preventing transmission of NANB Hepatitis but not HIV. In human recipients, the opposite outcome was eventually reported.

**23.303** Some at least of the procedures that were developed by commercial companies were protected by patents and, in the nature of things, prior publication of the inventive steps in the processes developed was most unlikely to have occurred at all and, if it happened, even more unlikely to have been comprehensive. Publication of a final specification would almost invariably take a period of years from filing of the original application.

**23.304** Dr Foster's paper following the Congress of the International Society of Haematology/International Society of Blood Transfusion in Budapest in August 1982 reported that there was at that time no final proof that the Behring product was free from NANB Hepatitis. The method of heat treatment of Hemofil T was not disclosed at the Congress. When, months later, Dr Prowse heard that the process involved dry heat treatment at 60°C, the methodology employed was not disclosed and to Dr Foster's knowledge has never been disclosed. Clinical trials of Hemofil T in 1982–83, including trials at St Thomas' Hospital in London, had shown that the product was less effective in inactivating virus than pasteurisation. That information was circulating informally within the industry, and within UK Government circles, in 1983 and 1984 (see paragraph 23.100). In October 1984, Professor Mannucci disclosed that, as far as AIDS was concerned, no patients treated with the product had apparently seroconverted after one year from treatment with Hemofil T (see paragraph 23.169). This was the first time that there was any evidence that dry heating inactivated, or might inactivate, the HIV virus. Events moved swiftly from then. By December 1984, dry heat treatment was operational in Scotland.

**23.305** In order to have advanced the provision of effectively heat-treated products so as to have ensured their supply in Scotland before the end of December 1984 as a matter of general prescription, the SNBTS would have required to be satisfied that the products were safe and effective to a degree that indicated that domestic research should be suspended or discontinued. The evidence has not disclosed any rational basis on which that could have been decided. Nor could one form or express any view on the likely reaction of the regulatory agencies if a licence application had been made.

*In general, was the approach taken to viral inactivation at the Protein Fractionation Centre in the period 1980–84 reasonable? In general, was the degree of priority accorded to viral inactivation by the Protein Fractionation Centre during this period reasonable?*

**23.306** These two questions relate to the work of the scientists explored in the evidence narrated in this chapter. They can be answered unequivocally in the affirmative.

## Appendix 1

### Commercial heat-treated coagulation factor products 1983–1991

#### Factor VIII

<u>ARMOUR PHARMACEUTICAL COMPANY</u>				
Product	FDA licence	Method	Temp	Time

## CHAPTER 24

### VIRAL INACTIVATION OF BLOOD PRODUCTS FOR HAEMOPHILIA THERAPY 1985–1987

#### Introduction

**24.1** This chapter considers the steps undertaken at the Protein Fractionation Centre, Edinburgh (PFC) between 1985 and 1991 to inactivate virus in blood products so as to prevent transmission of non-A, non-B Hepatitis (NANB Hepatitis)/the Hepatitis C virus (HCV).

#### The international context

**24.2** As discussed in Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*, developments in factor concentrate technology in Scotland at the end of 1984 and in 1985 were focused on an immediate response to the discovery of HIV infection in Scottish patients treated with SNBTS Factor VIII concentrate, particularly in the group of patients that came to be known as the Edinburgh Cohort. The experimental work that led to heat treatment of intermediate Factor VIII concentrate to inactivate that virus was prompted by information obtained at the Groningen Conference at the beginning of November 1984. Research and development do not, and did not, take place within hermetically sealed national boundaries.

**24.3** The international context provides an important focus for discussing developments in viral inactivation in the period covered by this chapter. In Appendix 1 to Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*, early developments in commercial heat-treated products were summarised without comment on their effectiveness. For the purposes of this chapter, the effectiveness of commercial production methods to inactivate viruses, and in particular NANB Hepatitis/HCV, is relevant. It is also material to identify, so far as possible, the dates when commercial manufacturers of blood products, who tended to have greater resources for research and development than state fractionators, were able to produce Factor VIII and IX concentrates that were sufficiently virally inactivated to prevent transmission of NANB Hepatitis/HCV.

**24.4** Dr Peter Foster led the necessary research in Scotland at the PFC. He gave evidence to the Inquiry that, over time, three methods of virus inactivation became accepted as being effective in inactivating NANB Hepatitis/HCV, namely (1) pasteurisation at 60°C for 10 hours, (2) solvent detergent treatment, and (3) dry heat treatment at 80°C for 72 hours (albeit pasteurisation and solvent detergent treatment have been associated with occasional transmission of virus, including Hepatitis C).<sup>1</sup> The Factor VIII and IX products which were accepted as safe from the transmission of NANB Hepatitis/HCV, together with such information as was available about the licensing and availability of the products in the UK are set out in Tables 24.1 and 24.2:<sup>2</sup>

<sup>1</sup> Dr Foster's statement on Heat Treatment, 1985–87 [PEN.017.1556] at 1586

<sup>2</sup> Dr Foster's statement on Heat Treatment, 1985–87 [PEN.017.1556] at 1584–85

**Table 24.1: Factor VIII products effective in inactivating NANB Hepatitis/HCV**

<b>Manufacturer</b>	<b>Product name</b>	<b>Virus Inactivation Method</b>	<b>FDA licence</b>	<b>UK licence</b>
Armour Pharmaceutical (manufactured in Germany by Beringwerke)	Humate-P	Pasteurisation at 60°C for 10 hours	May 1986	March 1984, but not generally available in the UK due to low product yield and very low level of exports from Germany
Armour Pharmaceutical (manufactured in the USA) <sup>3</sup>	Monoclote-P	Pasteurisation at 60°C for 10 hours	1990	December 1989 <sup>4</sup>
Alpha Therapeutic Company	Profilate SD	Solvent/detergent	July 1989	Not known if available in UK
Alpha Therapeutic Company	Profilate OSD	Solvent/detergent	May 1990	Not known if available in UK
Alpha Therapeutic Company	Alpha-8	Solvent/detergent	Pending as at November 1992	Uncertain, but supply in the UK would appear from a patient information sheet to be from December 1992
Baxter (Hyland Division)	Hemofil M	Solvent/detergent	February 1988	June 1994
Cutter Biological, Miles Inc.	Koate HS	Pasteurisation at 60°C for 10 hours	April 1986	To the best of Dr Foster's knowledge, not available in the UK
Cutter Biological, Miles Inc.	Koate HP	Solvent/detergent	March 1989	June 1994

**Table 24.2: Factor IX products effective in inactivating NANB Hepatitis/HCV**

<b>Manufacturer</b>	<b>Product name</b>	<b>Virus Inactivation Method</b>	<b>FDA licence</b>	<b>UK licence</b>
Armour Pharmaceutical	Mononine	Treated with sodium thiocyanate	August 1992	February 1993
Alpha Therapeutic Company	AlphaNine SD	Solvent/detergent	August 1992	October 1993
Cutter Biological, Miles Inc.	Konyne 80	Dry heat at 80°C for 72 hours	April 1991	Not known to Dr Foster if this product was available in the UK

<sup>3</sup> Dr Foster – Day 57, page 24<sup>4</sup> Dr Foster's statement on Heat Treatment, 1985–87 refers to a date of 1999. However, this date was corrected to 1989 during the Oral Hearing – see Dr Foster – Day 57, page 24

**24.5** The list was based on information contained in an article by Kasper and others, published by the journal *Transfusion* in 1993.<sup>5</sup> While Dr Foster did not know precisely when the production or supply of the products in the list took place in the UK, he considered that the dates when the products were available in this country would be close to either: (a) the earlier of the date on which a USA FDA licence or a UK licence was granted for the manufacture of the product; or (b) the date that a UK licence was granted for supply of the product in the UK.<sup>6</sup>

**24.6** During the Oral Hearings reference was also made to a product known as NYBC/Melville Biologics Coagulation Factor VIII-SD (a solvent-detergent product using Tri-n-butyl-phosphate and sodium chloride) which was referred to in table 5 of the 1993 Kasper paper. The product was licensed in the USA in 1985. Dr Foster said that Melville Biologics was the name of a facility operated by the New York Blood Centre which manufactured the product. He said that while it appeared in due course that the product would have been safe from Hepatitis C, it was not available in the UK.<sup>7</sup>

**24.7** Within the UK, the Plasma Fractionation Laboratory and the Blood Products Laboratory (PFL/BPL) were able to supply Factor VIII concentrate (8Y) to England, Wales and Northern Ireland from September 1985. Over time, the product was found to be safe from transmission of NANB Hepatitis/HCV. It can be seen from the above tables that, with the exception of the Behringwerke pasteurised product (which resulted in low product yields and was not generally available in the UK), the PFL/BPL were the first fractionators able to produce a Factor VIII product that events were to show did not transmit NANB Hepatitis/HCV (albeit, as discussed at 24.22 below, they were not able to produce sufficient product to meet the needs of all haemophilia patients in England and Wales).

**24.8** In Scotland, the PFC was able to make available for clinical trial in December 1986 a Factor VIII concentrate (Z8) which, over time, was found not to transmit NANB Hepatitis/HCV. That product was available for use from April 1987. That date compares favourably with the achievements of commercial manufacturers in providing safe products, as shown in Table 24.1. In addition, unlike the position in England, PFC were able to supply a sufficient quantity of product to meet the needs of all Haemophilia A patients in Scotland.

**24.9** Both the PFC and the PFL/BPL were able to supply a Factor IX concentrate (respectively, DEFIX and 9A) to meet demand from Haemophilia B patients from October 1985. These products were also found, over time, to be safe from the transmission of NANB Hepatitis/HCV. Table 24.2 indicates that a safe NHS product was available many years before commercial manufacturers supplied Factor IX concentrates that were safe from the transmission of NANB Hepatitis/HCV.

<sup>6</sup> Dr Foster's statement on Heat Treatment, 1985–87 [PEN.017.1556] at 1584. The dates the UK licence was granted for a product are, to the best of Dr Foster's knowledge, based on information provided by the UK Medicines and Healthcare Products Regulatory Agency (MHRA)

<sup>7</sup> Dr Foster – Day 57, pages 27–28

## Events in England

**24.10** As explained by Dr Jim Smith, Head of Research and Development at the PFL and the BPL, in 1984 the PFL was investigating, on a very small scale, the PFC's zinc/heparin precipitation process.<sup>8</sup> The aim of this process was to create a purer Factor VIII product by precipitating out (removing) the proteins fibrinogen and fibronectin.<sup>9</sup> There were two main reasons for seeking higher purity – firstly, to create a product which would dissolve more readily<sup>10</sup> and which could be administered to patients in smaller quantities of higher potency, and, secondly, to reduce the overall volume of product to be pasteurised, thus making it more straightforward to heat.<sup>11</sup>

**24.11** Dr Smith said that, when carrying out an experiment into this process, a PFL technician accidentally used a far greater quantity of heparin than was specified and, surprisingly, found an unusually heavy precipitate of fibrinogen and a high Factor VIII recovery.<sup>12</sup> Further research at the PFL showed that even better results could be obtained using heparin alone at much higher concentrations than had been used in the PFC's original zinc/heparin process.<sup>13</sup>

**24.12** This serendipitous discovery proved to be a key point in the development of 8Y and further work was carried out during 1984 to refine the steps in the process. Dr Smith explained that the heparin step allowed the PFL to:

[E]liminate a fiddly adsorption step in our current scheme and, after adding another precipitation method<sup>14</sup> conveniently emerging from our front-end work at the time, a ten-fold purification over the current product was achieved.<sup>15</sup>

**24.13** He added:

It often takes a long time to develop formulation and drying of a new concentrate, but we were fortunate to find a simple formulation which freeze-dried using the cycle applied to the current product. This very dry concentrate could then be heated at quite high temperatures without loss of solubility and with an acceptable loss of Factor VIII.<sup>16</sup>

**24.14** Although the PFL had conducted experiments on both wet and dry heating in the course of 1984,<sup>17</sup> the decision was taken in England, as in Scotland, to introduce immediate dry heating of the PFL/BPL's existing Factor VIII product upon hearing the news in November 1984 from the conference in Groningen that HIV could be inactivated by being dry heated to 68°C for one hour. Dr Smith explained that on his return from the meeting in Groningen, a small informal group at the PFL decided that the small, high-precision oven at the PFL would be used to heat retrospectively all batches of the current Factor VIII held in stock at the PFL and the BPL, at 70°C for 24 hours (or, if that proved unsatisfactory, 60°C for 72 hours).

<sup>8</sup> Dr Smith's statement on Viral Inactivation to 1985 [PEN.012.1551] at 1571

<sup>9</sup> See Dr Smith – Day 60, pages 20–21 and Dr McIntosh – Day 61, page 9

<sup>10</sup> For more details on the benefits of increased solubility see also Dr Smith – Day 60, pages 47–49

<sup>11</sup> See Dr Smith – Day 60, page 24. Dr Smith indicated that heat transfer, the control of temperature, and the removal of stabiliser and other impurities are all more straightforward with a smaller volume of liquid.

<sup>12</sup> Dr Smith's statement on Viral Inactivation to 1985 [PEN.012.1551] at 1571

<sup>13</sup> Ibid [PEN.012.1551] at 1572

<sup>14</sup> This was precipitation using glycine and sodium chloride which further concentrated the Factor VIII whilst removing some heparin and leading to a further fourfold reduction in fibrinogen and fibronectin. See Dr Smith – Day 60, page 24

<sup>15</sup> Dr Smith's statement on Viral Inactivation to 1985 [PEN.012.1551] at 1572

<sup>16</sup> Ibid [PEN.012.1551] at 1572

<sup>17</sup> See for example Dr Smith's statement on Viral Inactivation to 1985 [PEN.012.1551] at 1571; Dr Smith's supplementary statement [PEN.017.2198]; and Dr Smith – Day 60, pages 24–25

**24.15** The references to heating all batches of current PFL/BPL Factor VIII at 70°C for 24 hours and 60°C for 72 hours related to the existing English dry heat-treated intermediate purity products known as 8CRV (produced at the PFL) and HL (produced at the BPL), which were broadly equivalent to the PFC’s intermediate purity product, NY.<sup>18</sup> Batches which withstood heating at 60°C for 24 hours were known as HT1 and batches which survived heating to 70°C for 72 hours were known as HT2.<sup>19</sup> Dr Smith said that HT1 and HT2 were issued for general use in January 1985.<sup>20</sup> He indicated that the rationale for releasing HT1 and HT2 before 8Y was to try to protect haemophiliacs from HIV in the period up until 8Y could be released.<sup>21</sup>

**24.16** Dr Smith said that the BPL did not recall Factor VIII products that had already been issued in order to heat them. He stated:

[W]e did not do what some of the commercial companies did, which was to recover stocks of product from the haemophilia centre and even, I believe, from the fridges of haemophiliacs, their home treatment supply. I don’t believe we ever went that far or we even went back to the transfusion centres, which distributed our material. I believe we only retroheated the stocks in our own holding rooms.<sup>22</sup>

**24.17** As well as deciding in November 1984 to heat the existing intermediate purity Factor VIII product at 70°C for 24 hours, a decision was also taken at the PFL to complete the scale-up of production of the new high purity 8Y Factor VIII concentrate. It was further decided to prepare batches, dry heated at 80°C for 72 hours, for clinical trials with the intention that, if successful, production of 8Y would be transferred to the BPL. This would enable sufficient quantities of the product to be produced to supersede the existing intermediate purity product, heated at a lower temperature.<sup>23</sup>

**24.18** Dr Smith was asked at the public hearing whether the decision in November 1984 to proceed with the high purity 8Y product that could be heated at 80°C was taken with a view to inactivating HIV or NANB Hepatitis. He said it was certainly done to put HIV kill beyond all reasonable doubt. It was hoped that the product ‘could do a bit more damage to non-A non-B’, but he had ‘no hopes, to tell the truth, that this would deal with non-A non-B Hepatitis’.<sup>24</sup>

**24.19** The first pilot-scale production batch of the high purity 8Y product (80°C for 72 hours) was manufactured in November 1984. The product was rapidly scaled-up by the PFL from one litre in November 1984 to 300 litres by the end of January 1985, at which point there was sufficient material to begin clinical trials.<sup>25</sup> Dr Smith’s recollection was that Phase 1 clinical trials of the PFL product for safety and efficacy were carried out in March 1985, with Phase 2 clinical trials for virus safety starting in April 1985.<sup>26</sup> Once the BPL had successfully produced its first batches of 8Y, trials followed with its product.<sup>27</sup>

---

<sup>18</sup> See Dr Smith’s supplementary statement [PEN.017.2198] at 2198 – notwithstanding the different names, these products were virtually the same.

<sup>27</sup> Dr Smith – Day 60, page 30

**24.20** Full-scale production of 8Y commenced at the BPL in April 1985<sup>28</sup> with general release of the product to Regional Transfusion Centres in England in September 1985.<sup>29</sup>

**24.21** Factor VIII concentrate had never before been able to be heated at such high temperatures and the ability of Dr Smith's team to do so was a considerable achievement. Research facilities at the PFL were relatively 'basic' when compared with commercial producers (or, indeed, when compared with facilities at the PFC) and Dr Smith pithily explained, there was:

[A]mazement ... that two men and a boy working in a dustbin under socialised medicine could have come up with a solution before large pharmaceutical companies.<sup>30</sup>

**24.22** During the Inquiry hearings, Dr Smith's attention was drawn to a letter dated 24 July 1985 from Dr Richard Lane, the Director of the BPL, to Haemophilia and Regional Transfusion Directors in England and Wales, and to a passage stating that BPL's output of 8Y at that time could only meet about one third of demand for Factor VIII.<sup>31</sup> Dr Smith indicated that he did not have the information to make such a calculation.<sup>32</sup> However, he agreed that there was not enough 8Y in September 1985 to meet the total demand for Factor VIII in England and Wales for treatment of all haemophilia patients if 'total demand' included potential demand from patients using commercial products.<sup>33</sup>

**24.23** Dr Lane's letter contained a suggestion that the 8Y heat treatment process might be effective against NANB Hepatitis, indicating that:

Clinical trials at six Haemophilia Centres are in progress to gain evidence of reduction or elimination of viral transmission, and several patients have safely passed the point at which first evidence of NANBH virus transmission would normally occur with unheated Factor VIII.<sup>34</sup>

**24.24** Over time, further reports became available which gave increasing reassurance that 8Y might not transmit NANB Hepatitis.

**24.25** On 9 May 1986, Dr Smith presented a paper to an international symposium in Melbourne, Australia, giving interim results for 33 patients in England who had received 8Y and who had been followed up with regular liver function tests.<sup>35</sup> The paper expressed a degree of optimism that the product did not transmit NANB Hepatitis, noting that:

Although these are only interim results on a limited number of batches, we think we are justified in thinking that the severe heating has been more effective in preventing transmission of NANBH than the milder heating accorded to the Hyland and Armour products in studies published last year.<sup>36</sup>

<sup>32</sup> Dr Smith – Day 60, page 32

<sup>33</sup> Dr Smith – Day 60, page 33

<sup>34</sup> Dr Lane's letter of 24 July 1985 [DHF.003.0476]

<sup>35</sup> Smith et al, 'Interim results of surveillance for NANBH in patients receiving heated concentrates produced in England', *Developments in Biological Standardization* 1987; 67:323–325 [PEN.017.1264] and Dr Foster's statement on Heat Treatment, 1985–1987 [PEN.017.1556] at 1559

<sup>36</sup> *Ibid* [PEN.017.1264] at 1266

**24.26** The paper also advocated caution, however, by noting that:

It is too early to know whether NANBH transmission has been eliminated by severe dry heating or whether we may see transmission by only a few batches  
....<sup>37</sup>

**24.27** On 30 September 1986, Dr Smith provided further clinical results on the routine use of 8Y and 9A in England. The results were contained in an interim report, *Surveillance of previously untreated patients for possible virus transmission by BPL Factor VIII and Factor IX concentrates, 8Y and 9A*, prepared for a meeting of the UK Haemophilia Centre Directors Organisation (UKHCDO) in Edinburgh on 10 October 1986.<sup>38</sup> The report explained that in the spring of 1985 all Haemophilia Centre Directors in England were issued with a protocol for the detection of NANB Hepatitis, Hepatitis B and HIV in susceptible patients receiving BPL 8Y and 9A and were invited to collect data on this basis.<sup>39</sup> The summary of the results Dr Smith provided was restricted to patients who had no previous history of treatment with large-pool concentrates. It indicated that: (i) none of the patients ‘had any ALT or AST above 2.5 times the upper limit of the normal range’; (ii) no case of HIV seroconversion had been reported; and (iii) no evidence of infection with Hepatitis B had been seen.<sup>40</sup> The report concluded:

These data, showing no clinical or laboratory events attributable to transmission of the three main blood-borne viruses, may further encourage HCDs to use 8Y and 9A in previously untreated patients.<sup>41</sup>

**24.28** In his written evidence to the Inquiry Dr Smith indicated that these results were reason to be, ‘a little more upbeat, but not much’, explaining that the data in question were criticised throughout 1986–87 and that ‘using the only product “which hasn’t failed yet” does not necessarily denote confidence that it is going to be 100% successful’.<sup>42</sup>

**24.29** Dr Smith further explained that ‘the number of clean follow-ups at the end of 1986 was too small to either support or disprove the proposition that 8Y was statistically significantly safer from NANB Hepatitis transmission than commercial concentrates heated less severely’.<sup>43</sup> He ‘came to believe in the next few years that 8Y was probably safe, by sheer weight of good follow-ups and in particular the exposure of many batches of widely different provenance’ but he considered that liver enzyme tests (ie ALT tests) were unreliable and would not have vouched for 8Y’s safety ‘until application of the highly specific anti-HCV test’ in 1993.<sup>44</sup>

**24.30** Dr Foster advised the Inquiry that he was given a copy of the interim report by Dr Smith on 9 October 1986<sup>45</sup> and confirmed that this was the first occasion on which he saw written data on 8Y’s evaluation.<sup>46</sup> However, asked when it seemed to him to be likely

<sup>46</sup> Dr Foster – Day 56, page 69

that 8Y was free from NANB Hepatitis, Dr Foster said he had doubts whether the data could be used to say that 8Y was 'likely' to be free from NANB Hepatitis at this time.<sup>47</sup> He explained that in science one tends not to use words such as 'likely' and that products were either safe or unsafe. Dr Foster accepted, however, that safety could be measured statistically.<sup>48</sup>

**24.31** Dr Robert Perry was also asked when he thought that it seemed likely that 8Y was free from NANB Hepatitis. He advised that it was not until Dr Smith's report in September 1986 that 8Y's freedom from NANB Hepatitis would have been described as likely. He added the caveat, however, that 'even at this stage such a conclusion would have been regarded as cautionary and unconfirmed'.<sup>49</sup>

**24.32** Dr Bruce Cuthbertson also shared this view, stating in his written evidence that:

The letter from Dr Smith ... is the first evidence that I am aware of that 8Y could be potentially effective in significantly reducing the risk of NANBH .... The data available in Dr Smith's letter of September 1986 clearly showed a reduction in infectivity with NANBH, but was not yet conclusive of a lack of infectivity.<sup>50</sup>

**24.33** Asked to expand on his views, Dr Cuthbertson explained:

[C]learly there is a difference between the product which has a reduced risk from one which is absolutely free of evidence of infectivity. I think that's the point I was trying to get over in this text, that from the early work, it was clear that the risk of non-A non-B Hepatitis from the product was substantially less than from conventional unheated products. The infection rate with them was close to 100 per cent, whereas from the early evidence, a number of patients had not developed clinical evidence of non-A non-B Hepatitis. But to actually demonstrate freedom from infectivity is a very difficult process and takes time – or certainly took time then, when we were relying on indirect biochemical tests as a means of assessing infectivity.<sup>51</sup>

**24.34** On 16 September 1987 Dr Smith drew up a report for a UKHCDO AGM on 25 September 1987.<sup>52</sup> The report indicated that a two-year study, which was 'stricter' than the previous study, had shown a 'near zero' incidence of NANB Hepatitis transmission by 8Y or BPL's dry-heated Factor IX product, 9A.<sup>53</sup> Even at that stage, however, Dr Smith remained of the view that the effectiveness of severe dry heating in inactivating NANB Hepatitis had not been established. His report concluded:

It is not possible to determine the true incidence of transmission of NANBH by 8Y and 9A from this imperfect evidence, but the apparent near-zero incidence justifies the inclusion of a further series of patients in a more formally controlled prospective trial, to be co-ordinated by Dr Rizza and Dr Kernoff.<sup>54</sup>

<sup>54</sup> Ibid [SNF.001.1138] at 1141

**24.35** By 1988 further evidence was accumulating that 8Y was free from NANB Hepatitis. In particular, a paper by Dr Brian Colvin and others published in *The Lancet* in October 1988 reported that 32 patients who had been treated with 8Y had not developed NANB Hepatitis. The paper indicated that an additional, more rigorous, study was necessary, but noted that these data demonstrated that '80°C is highly effective in inactivating NANBH in coagulation factor concentrates'.<sup>55</sup>

**24.36** In 1993, once more sensitive and specific tests for HCV were available, a paper by Rizza and others reported that 27 previously untreated patients (PUPs) in England had received 24 batches of 8Y and that no evidence of infection by Hepatitis C, Hepatitis B or HIV had been found following these transfusions, thus finally confirming that 8Y was free from these viruses.<sup>56</sup>

## Developments in Scotland

1985

### The development of a high purity Factor VIII product and pasteurisation

**24.37** As indicated in Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*, (paragraphs 23.185 to 23.203) at the end of 1984 the PFC dry-heated stocks of its existing intermediate purity NY Factor VIII product at 68°C for two hours in an attempt to inactivate HIV, in response to the report from Groningen that HIV could be inactivated by dry heating at 68°C for one hour. This was regarded as an interim measure, which, in view of the extreme urgency brought about by the discovery that HIV had been transmitted by SNBTS Factor VIII concentrate, could be implemented immediately.

**24.38** Production of new batches of Factor VIII by the PFC had largely been suspended between October 1984 and January 1985 to allow for improvements required by the Medicines Inspectorate to be carried out at the plant.<sup>57</sup> The PFC's policy (and therefore the policy for Scotland) at the beginning of the year was intimated formally in a letter by Dr Perry to Dr Duncan Thomas, from the National Institute for Biological Standards and Control (NIBSC), dated 8 January:<sup>58</sup>

- All FVIII issued from PFC had been heat-treated since mid-December 1984;
- PFC would recall all existing regional stocks of non-heat treated FVIII for heating and reissue;
- The heating conditions applicable at that date were 68°C for 2 hours in the dry state. Those conditions were the best that could be achieved with the existing product without compromising solubility, and in the knowledge that a joint CDC/Cutter study had suggested that they might provide 4–5 logs inactivation of HTLV III virus;
- Analytical specification and *in vivo* characteristics were identical to the unheated precursor;
- There was no significant deterioration as a result of the changes;

<sup>57</sup> SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1346

<sup>58</sup> Dr Perry's letter to Dr Thomas of 8 January 1985 [SNB.007.4734]

- Plans were well advanced for the manufacture of a new product, with a modest reformulation involving the addition of carbohydrate, which would be subjected to more extreme conditions of temperature and time.

**24.39** Developments were in hand on the last point. When the PFC recommenced production on 20 January 1985, sucrose was added to all intermediate purity Factor VIII to enable heating at 68°C for 24 hours with the objective of achieving a greater margin of safety against HIV. It was correctly thought, however, that the 68°C/24 hours product was unlikely to be free from risk of transmitting NANB Hepatitis.<sup>59</sup>

**24.40** Despite the introduction of dry heat treatment of the existing intermediate purity Factor VIII product in an attempt to inactivate HIV, a progress report produced by Dr Foster for the meeting of the SNBTS Factor VIII Study Group in February 1985 commented that the development of a high purity product that could be pasteurised ‘would seem to be still the preferred option’.<sup>60</sup>

**24.41** Dr Foster’s progress report explained that the aim at that stage had been to apply pasteurisation to the high-purity Factor VIII product under development in collaboration with Dr Alan Johnson of New York University (NYU). PFC had been sufficiently impressed with the NYU process that in October 1984 a decision had been taken to shelve further research into the existing zinc heat-treated method (ZHT) ‘so that maximum effort could be given to the newer method’.<sup>61</sup>

**24.42** When asked to explain the attractions of the NYU process and pasteurisation, Dr Foster said:

[T]he objective was to have a product that was safe from non-A non-B Hepatitis, and at that time pasteurisation was the front runner in terms of the knowledge that existed, in terms of what might be safe, and in order to make that process work in our production operation, I wanted to increase the degree of purification so that I could reduce the volume of pasteurisation by maybe 50- or 100-fold, and the Johnson process would allow me to do that and that’s why we gave priority to that at that time.<sup>62</sup>

**24.43** Dr Foster explained that the NYU product was significantly more pure than the PFC’s existing intermediate Factor VIII product NY, pointing out that, ‘[for] the NYU product, we were looking for an increased purification of the order of 100- to 200-fold’.<sup>63</sup>

**24.44** While expressing a preference for wet heat treatment (pasteurisation), the progress report commented that ‘recent information concerning HTLV-III’ had led to dry heating of the existing product. It commented that ‘severe heating of the freeze dried powder may be possible (Smith, unpublished results)’.<sup>64</sup> The mention of ‘severe heating’ in the report was a reference to the work by the PFL/BPL on 8Y discussed above. The impression given at that stage, however, was that resort to dry heat treatment of the PFC’s product was a temporary measure.

**24.45** Dr Ronald McIntosh, a biochemist at the PFC during the relevant period, also gave evidence to the Inquiry as to the rationale for the move, in late 1984, from developing the ZHT process to developing the NYU process. He explained that there were significant problems with the ZHT process, including: the need to add large percentages (20–40%) of carbohydrate stabilisers to allow for satisfactory Factor VIII recovery (resulting in a solution with a large volume that was very viscous and hence difficult and time-consuming to process); the precipitation step (where Factor VIII was recovered from the high concentration of stabilisers) was difficult to control; and lower yields for ZHT than the existing intermediate Factor VIII product (which would have had a negative impact on the PFC's policy of self-sufficiency).<sup>65</sup>

**24.46** Dr McIntosh was asked whether it would have been practical to ramp up the ZHT process to achieve full production. Dr McIntosh replied:

It would not have been feasible. The difficulties in processing such large volumes of viscous solution and also adding additional processing steps to fit into the available working schedule in production, would have made it very difficult to do.<sup>66</sup>

**24.47** In contrast to the problems with ZHT, the NYU process appeared more promising. Dr McIntosh indicated in his oral evidence that the NYU process 'would allow us to get the purification that was needed to aid pasteurisation, without compromising yield'.<sup>67</sup> He explained in more detail the initial research carried out on the NYU process between late 1984 and the middle of 1985, indicating that various changes were made to the process with the aim of making it compatible with the requirements for Factor VIII production at PFC.<sup>68</sup> These included: the addition of a zinc heparin precipitation step derived from the ZHT process to filter out unwanted fibrinogen and fibronectin; the use of an ion exchange gel different from the gel used by Dr Johnson; the substitution of calcium with other salt combinations which were physiologically more acceptable; and the development of a more stable formulation.<sup>69</sup>

**24.48** Although pasteurisation was, in principle, still the PFC's preferred option for viral inactivation at the start of 1985, the PFC appears to have carried out relatively little pasteurisation work in the first few months of the year. In that regard, another report for the meeting of the SNBTS Factor VIII Study Group on 7 February 1985, *Update Paper on Viricidal Action Since Last Meeting One Year Ago*, indicated that the PFC's work on pasteurisation was 'in abeyance' at this time.<sup>70</sup> This was apparently due to the shelving of the ZHT project (see above) and because of pressure on the PFC to complete dry heat treatment of all existing intermediate purity NY Factor VIII batches (ie the interim measure to inactivate HIV introduced at the end of 1984 as an emergency response to the infection of Edinburgh patients with HIV which temporarily diverted attention from NANB Hepatitis).<sup>71</sup>

<sup>70</sup> Factor VIII Study Group update paper [SNB.007.4911]

<sup>71</sup> Factor VIII Study Group update paper [SNB.007.4911]

**24.49** The February 1985 *Update Paper* noted that a ‘watching brief’ would be kept on detergents and organic solvents as potential methods of viral inactivation. Dr Foster said that the PFC was aware of the research being carried out elsewhere into the use of solvent detergent as a method of viral inactivation.<sup>72</sup> He explained, however, that this method was only effective against viruses that had ‘lipid envelopes’, and that given that the structure of the NANB Hepatitis virus or viruses was not clear at the time, the solvent detergent method was less obviously attractive than heat treatment. Dr Foster also noted that an additional downside to the solvent detergent method was that it involved adding and then removing toxic chemicals from the product, which at the time could not readily be applied to the PFC’s manufacturing processes.

**24.50** Another report for the February 1985 meeting of the Factor VIII Study Group, prepared by Professor John Cash, noted that preliminary clinical evaluation studies (bioacceptability, clinical efficacy and residual infectivity) were planned for SNBTS Factor VIII products, both pasteurised (60°C for 10 hours and an additional period at 70°C) and dry heated (68°C for 24 hours), and outlined the PFC’s rationale for examining both wet and dry heat treatments. The report commented that:

The need to assess both dry and wet heat arises because the former is less costly and subject to lower yield penalties. However the wet heat is likely to be more virucidally effective.<sup>73</sup>

**24.51** At this time, research into the heat treatment of Factor IX was also continuing. These studies were carried out in collaboration with the BPL.<sup>74</sup> Difficulties had been encountered in arranging animal model studies using dogs, which were needed to test for thrombogenicity. According to a report by Professor Cash in March 1985:

Despite considerable efforts over the last 2 years it has only very recently been possible to make arrangements for animal model (thrombogenicity) testing. These were recently begun and provided all goes well it is anticipated that a heat treated product will be available for preliminary clinical evaluation by late Spring of 1985. The product currently the candidate for heat treatment is DEFIX.<sup>75</sup>

**24.52** A meeting of the SNBTS and Haemophilia Directors took place on 7 March 1985.<sup>76</sup> A paper drawn up for this meeting by Professor Cash summarised the position as regards heat treatment of Factor VIII by PFC. It explained that the current product was a reaction to AIDS. The period from November 1984 to March 1985 had been difficult. Professor Cash reported:

It has been a period in which disaster struck in Australia and in which both UK transfusion services were implicated in the transmission of HTLV-III viruses.<sup>77</sup>

**24.53** The standard routine SNBTS issue, Dry (Intermediate) HT (68°C for two hours) involved the dry heat treatment of the existing intermediate product without the addition

<sup>72</sup> Dr Foster – Day 57, page 28. Dr Foster noted, however that, in 1991, once more information became available on the effectiveness of the solvent detergent method PFC started to treat high purity Factor VIII with a solvent detergent method.

<sup>73</sup> SNBTS Heat Treated Factor VIII: Preliminary Clinical Evaluation Studies, February 1985 [SNF.001.3176]

<sup>75</sup> Notes for Scottish Health Service Haemophilia Centre/Transfusion Service Directors’ Meeting: March 1985 [SNB.001.5357] at 5368

<sup>76</sup> Minutes of meeting [SNF.001.0241]

<sup>77</sup> Notes for Scottish Health Service Haemophilia Centre/Transfusion Service Directors’ Meeting: March 1985 [SNB.001.5357] at 5362. The Australian incident appears to have related to the deaths of three babies in Brisbane from AIDS.

of stabilisers.<sup>78</sup> According to the paper, it was anticipated that this product would remain the standard SNBTS Factor VIII product until autumn 1985 and that preliminary clinical evaluations of the new dry-heated product (68°C for 24 hours with the addition of stabilisers) would be completed by the end of May 1985. The paper indicated that work on the high purity NYU product was ‘proceeding satisfactorily’ and that, ‘decisions have not yet been made with regard to the heat treatment regime but at the present time wet heat treatment is favoured’.<sup>79</sup>

**24.54** Dr Perry also drew up a paper for this meeting, which summarised progress in heat treatment work at the PFC.<sup>80</sup> Dr Perry’s paper indicated that current heat-treated material (68°C/2 hrs) was available for the treatment of all haemophilia patients in Scotland and Northern Ireland and that an ongoing programme was underway to subject all existing stocks (including those recalled from Regional Transfusion Centres) to these heating conditions, with stocks anticipated to last until autumn 1985.<sup>81</sup> The paper noted that clinical trials of the intermediate purity NY Factor VIII product, dry-heated at 68°C for 24 hours, should be planned and implemented so as to ensure continuity of product supply later in the year.<sup>82</sup> By this date, it had been established that this product could be heated in the dry state to 68°C for 24 hours without reducing solubility. On 4 March 1985, Dr Perry had written to Dr Frank Boulton intimating that two batches of this product would be available for clinical trials within two weeks.<sup>83</sup> One hundred vials of two separate batches were arranged to be sent on or around 13 March 1985.<sup>84</sup> At the meeting, Dr Perry informed members that the new intermediate Factor VIII concentrate, dry-heated at 68°C for 24 hours, was ready for clinical evaluation. It was remitted to a Working Group to facilitate clinical evaluations in Scottish centres. It was also proposed that the Working Group should look into involving hospital Ethical Committees in evaluation proposals.<sup>85</sup>

**24.55** By late March 1985 a degree of progress had been made as regards the clinical trials mentioned in Dr Perry’s paper. On 2 April 1985, Professor Cash wrote to Professor Arthur Bloom with arrangements for trials of the latest product heat-treated at 68°C for 24 hours.<sup>86</sup> Professor Bloom, who had been hesitant about committing resources to the Scottish project earlier in the year,<sup>87</sup> responded with proposals on 10 April 1985.<sup>88</sup>

**24.56** However, the plan to proceed to clinical trials of safety and efficacy in Scotland led to some disquiet among haemophilia clinicians in the absence of compensation arrangements for participants in the trial.<sup>89</sup> In response to a request from Dr Boulton to test the 68°C/24 hours material, Professor Christopher Ludlam indicated in a letter dated 19 March 1985 that if compensation arrangements were not put in place he would have to seek ethical approval before continuing with the trial (Professor Ludlam’s letter noted that it would take some time to gain such approval).<sup>90</sup> There also appears to have been a degree of reluctance from the Glasgow Royal Infirmary in undertaking clinical trials.<sup>91</sup>

<sup>86</sup> Professor Cash’s letter to Professor Bloom of 2 April 1985 [SNB.007.5055]

<sup>87</sup> Professor Bloom’s letter to Professor Cash of 15 February 1985 [SNB.007.4932]

<sup>88</sup> Professor Bloom’s letter to Professor Cash of 10 April 1985 [SNB.007.5064]

<sup>89</sup> The background to the issue of compensation in this context is discussed more fully at paragraph 24.138 below.

<sup>90</sup> Professor Ludlam’s letter to Dr Boulton of 19 March 1985 [SNB.005.7320]

<sup>91</sup> Professor Cash’s letter to Dr Forbes of 11 March 1985 [SNB.007.5036]

**24.57** The discussions in March 1985 highlight a feature of SNBTS policy in relation to the rolling out of new products reflecting technological developments. All existing stocks, heat-treated at 68°C for two hours were to be used until exhausted in the autumn. The new formulation, prepared for heating at 68°C for 24 hours, would be held unheated pending trials of the preliminary batches, and issued (after dry heat treatment) in July or August when sufficient clinical experience of the product had accumulated. The policy of exhausting existing supplies before new (and, theoretically, superior) products were released was to become a recurrent theme.

**24.58** Professor Cash wrote to Professor Ludlam on 22 March 1985, expressing concern that his decision on trial of the product was likely to impact on progress, and commenting on the risk that delay could affect supplies of Factor VIII in mid-1985.<sup>92</sup> Professor Ludlam replied on 4 April 1985 expanding on his position as regards compensation arrangements and indicating that he was prepared to assist once he had received the full product specification.<sup>93</sup> However, the letter notes that Professor Ludlam would be, 'looking for concrete guidance from the Department' (that is, guidance from the SHHD on compensation arrangements).<sup>94</sup> Dr Boulton reacted to these developments in a letter to Professor Cash dated 19 April 1985. In his letter Dr Boulton queried Professor Ludlam's version of events, but indicated that he would contact Professor Ludlam once he had full details of the product, so as to come up with a 'mutually acceptable protocol'.<sup>95</sup> There appears to have been some progress thereafter. On 29 April, Professor Ludlam wrote to Professor Cash that he had sought ethical approval and was arranging for four haemophilia patients to 'come up' in the very near future.<sup>96</sup>

**24.59** On 15 May 1985 a meeting of the Haemophilia and Blood Transfusion Working Group took place.<sup>97</sup> Dr Perry reported that the PFC continued to manufacture FVIII, including 2% sorbitol, dry-heated at 68°C for 24 hours. Preliminary clinical evaluation studies had been good, and he said that the PFC could now proceed to heat all unheated stocks of FVIII. Meantime, as noted above at paragraph 24.15, the PFL and the BPL had already proceeded with production and release for general use of HT1 and HT2 in January 1985. At the Edinburgh meeting of the British Society for Haemostasis and Thrombosis on 26 March 1985 progress with the BPL's product prepared by heating freeze-dried concentrate at 60°C for 72 hours was reported, together with information on the outcome of trials.<sup>98</sup> Prospective studies on three surgical patients had shown no evidence of transmission of NANB Hepatitis. Development work proceeded at PFL on 8Y. From December 1984, the PFL had scaled up 8Y for clinical trial for safety and efficacy. Trials were conducted satisfactorily in February 1985 by which time 8Y had become the sole Factor VIII product manufactured at the PFL. Haemophilia Directors were informed in March 1985 that 8Y was available for clinical trial. The BPL followed through with manufacture of 8Y in May 1985.<sup>99</sup> The English Factor VIII development programme was now clearly ahead of Scottish work on dry heat treatment of FVIII.

<sup>92</sup> Professor Cash's letter to Professor Ludlam of 22 March 1985 [SGH.003.1967]

<sup>99</sup> Dr Smith's statement on Viral Inactivation to 1985 [PEN.012.1551] at 1574

**24.60** On 15 May, there was further discussion of heat treatment of Factor IX. It had been reported in February that dog studies of thrombogenicity had been instructed.<sup>100</sup> The minutes of 15 May disclose that Dr Perry informed the meeting that:

[T]he heat treatment of Factor IX was a high priority project and that dog tests were underway at Cambridge. PFC expected initial clinical evaluation studies to begin in 2/3 months' time. Dr Cash was pleased to inform members that the first results received from Cambridge looked promising and tests had shown no trace of DIC in the heat treated product.<sup>101</sup>

**24.61** However, progress had not been sufficient to satisfy demand for Factor IX. In May 1985, when the SNBTS stopped supplying its unheated Factor IX, Haemophilia Directors purchased heated commercial Factor IX from the USA.<sup>102</sup>

**24.62** On 4 July 1985, results from Professor Bloom, added to results from Edinburgh, indicated excellent validation of the biological efficacy of the PFC's 'latest batch' of heat-treated Factor VIII.<sup>103</sup> The product would have been dry-heated for 24 hours at 68°C (the 'second generation' Factor VIII<sup>104</sup>) in May 1985, if it was the same as the Edinburgh test material.

**24.63** On 15 July 1985 Dr Perry sent a letter to Dr Lane, Director of BPL, which indicated that both the PFC and the BPL were involved in the clinical evaluation of their respective heat-treated Factor VIII products and noted that, as regards PFC's 68°C/24 hours product, the PFC was 'primarily concerned with half-life and recovery since it is unlikely that we will achieve freedom from NANB'.<sup>105</sup> The letter also included a copy of the PFC's heating protocol with the explanation that:

[S]ince we anticipate future trials of a product subjected to more substantial conditions of viral inactivation, I believe it would be helpful if we exchanged our respective trial protocols with a view to achieving commonality wherever possible.<sup>106</sup>

**24.64** Over the summer of 1985, further research continued. It was not expected that Factor VIII heated at 68°C for 24 hours would clear the product of NANB Hepatitis. New equipment had been ordered to achieve higher temperatures in the production process. The first heat treatment cabinet commissioned for the purpose was received and commissioned by the SNBTS in July 1985.<sup>107</sup> It was used thereafter for the dry heat treatment of Factor VIII concentrate at 68°C and Factor IX concentrate at 80°C. This equipment made it possible to proceed to more effective heat treatment.

**24.65** On 16 August 1985, at a meeting of the PFC Heads of Department/Section Managers, Dr Perry reported that heat-treated Factor IX product, DEFIX (dry heat treated at 80°C for 72 hours) 'had now been issued for routine use at Edinburgh Centre and further

issues would be made to remaining centres in September/October 1985'.<sup>108</sup> On 26 August 1985, he wrote to the Scottish Transfusion Directors and NIBTS Director intimating that the PFC had almost exhausted their stocks of the original heat-treated product (68°C for two hours) and that the 'new' product would be issued within the next two months.<sup>109</sup>

**24.66** On 4 September 1985 the PFC commenced routine issue of its intermediate purity NY Factor VIII, dry heated at 68°C for 24 hours.<sup>110</sup> The 68°C/2 hours product continued to be released until 13 September 1985 after which it was recalled.<sup>111</sup>

**24.67** By October 1985, the PFC's heated Factor IX product (HT DEFIX), dry heat-treated at 80°C for 72 hours, was routinely distributed to all centres.<sup>112</sup> Existing stocks of unheated Factor IX were subsequently recalled and destroyed.<sup>113</sup>

**24.68** Over the second half of 1985, there were several technological developments at the PFC. Where necessary these will be described in some detail. In addition to the need for new ovens, they included new equipment for purification, specified in October 1985, and delivered by Pharmacia, the manufacturer, in mid-1986;<sup>114</sup> and the development of innovative freeze-drying procedures and associated equipment arising from study of the BPL's production methods for 8Y.<sup>115</sup> The implementation of developments in scientific research required sophisticated hardware.

**24.69** The lead time from discovery to full production was unavoidably long in some cases. In this, as other areas of research and development, laboratory scale experiments with small quantities of material might provide proof of principle, but scaling up to routine production of hundreds of litres of material safe for therapeutic application in patients required proof of practicability and effectiveness at each successive stage in the production process. And the equipment required for novel manufacturing processes often had to be custom-designed and made.

### Dr McIntosh's discovery

**24.70** By October 1985 there was sufficient volume of the NYU high purity Factor VIII product being developed by the PFC for work to progress to freeze-drying experiments.<sup>116</sup> Initial experiments were carried out on the high purity product using the established process for freeze-drying the PFC's intermediate purity NY Factor VIII.<sup>117</sup> However, this freeze-drying process led to the destruction of the high purity NYU product.<sup>118</sup> Dr McIntosh

See also Dr McIntosh's statement on Viral Inactivation 1985–1987 [PEN.017.1234] at 1235. For a detailed overview of the workings of the PFC's established freeze drying process see Dr McIntosh – Day 61, pages 38–40.

<sup>118</sup> SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1350. See also Dr Foster – Day 56, pages 87–88

explained that freeze-drying using the standard production cycle ‘completely failed’ and that ‘the primary drying conditions were much too warm, so the product literally boiled instead of sublimation occurring’.<sup>119</sup>

**24.71** As a result of this failure, the PFC was forced to design a new freeze-drying process from first principles in order to freeze-dry the high purity NYU product.<sup>120</sup> The key features of the re-designed freeze-drying process were: (i) a much lower primary drying temperature and a longer primary drying phase and (ii) a defined time and temperature in the secondary drying phase (as opposed to removing product when it was judged that it had dried sufficiently<sup>121</sup> under the existing ‘pressure hold test’).<sup>122</sup>

**24.72** On 21 October 1985, Dr McIntosh conducted a freeze-drying and heat treatment experiment based on this new process on a sample of high purity NYU Factor VIII prepared in the PFC’s research laboratory.<sup>123</sup> A sample from a standard vial of intermediate purity Factor VIII was also included as an experimental control.<sup>124</sup> Although the high purity product tolerated the new freeze-drying process, it failed to withstand dry heat treatment at 80°C.<sup>125</sup> In contrast, the intermediate purity product was found to have withstood both the freeze-drying process and dry heat treatment at 80°C.<sup>126</sup> Dr Foster included a description of the experiment in a memo to Dr McIntosh dated 22 October 1985.<sup>127</sup> This memo did not mention the experimental control,<sup>128</sup> but indicated that the heated NYU high purity product ‘looked overheated’, did not re-dissolve properly and had no Factor VIII activity. A list of possible areas to research was set out.<sup>129</sup> Dr Foster explained that the result of the experiment was ‘very surprising’ as he had ‘expected the high purity product to be able to withstand dry heating at 80 and even to be able to withstand heating beyond 80’.<sup>130</sup> There had been no expectation that the intermediate purity product would be able to withstand heating to that temperature. The expectation until that point was that increased purity was the key to heating at higher temperatures.

**24.73** In the following weeks, the PFC conducted further investigations into the reasons for the unexpected result of the experiment and the possibilities regarding dry heat treatment. The initial experiment was repeated,<sup>131</sup> and on 11 November 1985 Dr Foster drew up handwritten laboratory notes detailing further dry heat treatment experiments (80°C/72 hours) involving the PFC’s existing intermediate purity Factor VIII (referred to by its product code NY 776) and the high purity product (product code NYU 195), and took photographs of the results.<sup>132</sup> On 21 November 1985, Dr McIntosh carried out

<sup>119</sup> Dr McIntosh – Day 61, pages 40–41. Sublimation is the process of transformation directly from the solid phase to the gas phase without passing through an intermediate liquid phase.

<sup>120</sup> SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1350 and Dr McIntosh – Day 61, page 41. <sup>127</sup> Dr Foster’s memo to Dr McIntosh of 22 October 1985 [PEN.017.1376]. According to Dr Foster the reason why he wrote to Dr McIntosh and not the other way round was because Dr McIntosh had given him the results in order that Dr Foster could reflect on them – see Dr Foster – Day 56, page 91.

<sup>128</sup> See Dr McIntosh – Day 61, page 35 for confirmation

<sup>129</sup> Dr Foster’s memo to Dr McIntosh of 22 October 1985 [PEN.017.1376]

<sup>130</sup> Dr Foster – Day 56, page 89

<sup>131</sup> See Dr Foster – Day 56, page 92. The Inquiry does not, however, have a record of this having occurred.

<sup>132</sup> Dr Foster’s notes dated 11 November 1985 [PEN.017.1378] and Dr Foster – Day 56, pages 105–106

an experiment to examine the feasibility of dry heating intermediate Factor VIII at high temperatures (ie the ZHT product purified using zinc/heparin precipitation).<sup>133</sup> Notes of these experiments were made on an existing method sheet for the ZHT product, with the elements related to the pasteurisation step deleted by hand.<sup>134</sup> When asked during the Inquiry hearings to explain what this experiment involved Dr McIntosh said:

[T]his is one of the early experiments ... taking the – as I call, front end of the ZHT process and not carrying on into pasteurisation but freeze-drying that material, preparing that material for freeze-drying in such a way that it could be terminally dry heat-treated.<sup>135</sup>

**24.74** Dr McIntosh confirmed in oral evidence that these experiments were the first laboratory scale experiments on the product that would, in due course, become known as Z8.<sup>136</sup>

**24.75** Meanwhile, on 13 November 1985 Dr Foster wrote to Dr Smith at the BPL enclosing some recent PFC publications. He also said:

One question I've been meaning to ask you; what are the freeze drying conditions for your new FVIII concentrate (especially during primary drying). We have some preliminary data that suggests that drying conditions may be particularly critical for the subsequent sensitivity of both protein and virus components to heating (not unexpected).<sup>137</sup>

**24.76** Dr Foster said that this question about the freeze-drying procedure for 8Y, which was known to tolerate dry heat treatment at 80°C/72 hours, arose from Dr McIntosh's discovery in the laboratory scale experiment that intermediate purity Factor VIII tolerated dry heat treatment at 80°C/72 hours.<sup>138</sup> This discovery led Dr Foster to consider that the freeze-drying process might be important in relation to the ability of Factor VIII to tolerate dry heat treatment.<sup>139</sup> Although Dr McIntosh's discovery was surprising at the time, Dr Foster indicated during the Inquiry hearings that once he had had the opportunity to consider it further he came to the conclusion that, on reflection, it was not entirely surprising that the freeze-drying procedure might influence the subsequent heat treatment step given that it was not unusual in fractionation for the success of a manufacturing step to be influenced by a preceding step or steps.<sup>140</sup>

**24.77** Dr Smith responded to Dr Foster in a letter of 11 December 1985 which included details of the freeze-drying conditions at the BPL for 8Y.<sup>141</sup> Dr Foster said that the information supplied by Dr Smith 'confirmed that the new freeze drying cycle devised at the PFC was similar in design to that being used to freeze dry 8Y, consistent with this being the key aspect of the 8Y process, rather than the degree of purification'.<sup>142</sup>

## Change of direction

**24.78** By late 1985 work at the PFC had progressed far enough that it was possible to re-assess the various options regarding heat treating Factor VIII. In particular, on 18 December 1985 Dr Foster sent a memorandum entitled *FVIII Progress and Options* to Dr Perry. The memorandum explained that it was ‘a brief summary of where we are at with the NYU [high purity] FVIII project and the various options that are available to us to achieve a product heated at 80°C for 72 hours’.<sup>143</sup>

**24.79** The NYU project was summarised first and it was explained that the latest attempt at heating the product on 17 December 1985 had given a negative result (the speculative suggestion was that this was due to a problem with the product’s ‘ionic strength’).<sup>144</sup> Three options for the NYU project were set out:<sup>145</sup>

- Option 1.1. Heat material at high ionic strength but with lysine added to provide extra stabilisation.
- Option 1.2. Reduce the ionic strength to a subcritical level (with or without lysine).
- Option 1.3. Recover the whole FVIII molecule instead of FVIIIc. It was noted that this would entail a loss of purity of 25%–50% and that it would be an ‘ideological’ step backwards.

**24.80** The memorandum also set out three options for the development of PFC’s existing intermediate purity NY Factor VIII product.<sup>146</sup> These options were:

- Option 2.1. Heating the existing product at 80°C for three days, which apparently could be achieved by using a more conservative freeze-drying regime.<sup>147</sup>
- Option 2.2. Purifying the existing product a little further so that the solution could be concentrated by ultra-filtration so as to reduce fill volume and hence the freeze-drying time (this could apparently be achieved by zinc precipitation of cryoprecipitate).
- Option 2.3 Copying the BPL method. It was noted, however, that, ‘a fair amount of work would be needed to finish this project off and it is not an attractive proposition for transfer to production’.<sup>148</sup>

**24.81** The memorandum indicated that, ‘unfortunately all of these options compete for resources, particularly FVIII assays, still the rate limiting factor’,<sup>149</sup> and concluded with the recommendation to:

[G]ive options 1.1 and 1.2 top priority but to continue on 1.3 and 2.2 so that we can either change tack on the NYU project if progress is slow or produce a modification of our existing product if pressure on heat inactivation demands it.<sup>150</sup>

<sup>143</sup> Dr Foster’s memo to Dr Perry of 18 December 1985 [SNB.013.6680]. See also Dr Foster – Day 56, pages 101–103

<sup>144</sup> Dr Foster’s memo to Dr Perry of 18 December 1985 [SNB.013.6680]

<sup>145</sup> Dr Foster’s memo to Dr Perry of 18 December 1985 [SNB.013.6680] and also Dr Foster – Day 56, page 103

<sup>146</sup> Dr Foster’s memo to Dr Perry of 18 December 1985 [SNB.013.6680] at 6681

<sup>147</sup> Dr Foster’s memo to Dr Perry of 18 December 1985 [SNB.013.6680] at 6681. According to Dr Foster’s oral evidence, the reference to a ‘conservative freeze drying regime’ means a slower, more gentle freeze drying process – see Dr Foster – Day 56, pages 103–104

<sup>148</sup> Dr Foster’s memo to Dr Perry of 18 December 1985 [SNB.013.6680] at 6681

<sup>149</sup> For details on why access to assays, by definition, limited the rate of research and development see: Dr Foster – Day 56, page 108–109 and Dr Foster’s statement on Heat Treatment, 1985–1987 [PEN.017.1556] at 1582–83

<sup>150</sup> Dr Foster’s memo to Dr Perry of 18 December 1985 [SNB.013.6680] at 6681

**24.82** Dr Foster was asked during the Inquiry hearings whether his preference at the time was to continue to give priority to the NYU high purity project, but to have option 2.2 (further purification of the intermediate product) as a back-up plan. He confirmed that this was the case and explained that, in his view, pasteurisation was still his preference for the high purity product as there ‘was more evidence to support it in terms of achieving a safe product’.<sup>151</sup> In addition, however, a high purity product would also be compatible with alternative viral inactivation techniques such as dry heat treatment or solvent detergent.<sup>152</sup> He added:

[O]ne of the factors in my thinking at this time was the knowledge that the haemophilia directors were very keen on having higher purity products and they were concerned about the possibility that there might be some immune disturbance in patients as a result of the lower purity products. So that was an added aspect to consider with this higher purity material.<sup>153</sup>

**24.83** Dr Foster indicated that the statement, ‘if pressure on heat inactivation demands it’, was a reference to work carried out by Dr Alfred Prince in the USA which had questioned the effectiveness of dry heat treatment against HIV<sup>154</sup> and pointed out that for the PFC this was a potential concern, explaining that, ‘looking back now, we kind of see non-A non-B as equal or even perhaps of more concern but at this point in time it was HIV that was driving everyone’s thinking’.<sup>155</sup>

**24.84** The question of which option or options to proceed with was discussed at a meeting between Drs Foster, McIntosh, Perry and Cuthbertson on 23 December 1985.<sup>156</sup> Other than a brief diary entry by Dr Foster on this date, which simply refers to ‘FVIII meeting’, there was no formal record of the meeting.<sup>157</sup>

**24.85** During the Inquiry hearings, Drs Foster, McIntosh, Perry and Cuthbertson were each asked for their recollections of this important meeting.<sup>158</sup> All indicated that the purpose of the meeting was to discuss Dr Foster’s memo of 18 December and the two main heat treatment options – ie continuing with the high purity NYU process or moving to severe dry heat treatment of the PFC’s intermediate Factor VIII product.<sup>159</sup> There appears to have been a degree of urgency in holding this meeting as it was scheduled immediately before the Christmas holidays when the PFC would not have been in production (a non-urgent meeting would normally have been left until the New Year).<sup>160</sup>

**24.86** Dr Foster explained that his view before the meeting had been that the PFC should continue to prioritise the high purity NYU process, whilst exploring alternatives.<sup>161</sup> In contrast, Dr McIntosh was of the opinion that the PFC should pursue severe dry heat

<sup>151</sup> Dr Foster – Day 56, page 112

<sup>152</sup> *Ibid*

<sup>153</sup> Dr Foster – Day 56, page 110. ‘Antigen overload’, the theory that immune disturbance was related to repeated infusions of ‘impure’ factor products is discussed in Chapter 11, *HIV/AIDS Aetiology*. <sup>159</sup> See Dr Perry – Day 58, page 16; Dr Cuthbertson – Day 57, page 51; Dr McIntosh – Day 61, page 48; and Dr Foster – Day 56, pages 113–115.

<sup>160</sup> See Dr Foster – Day 56, pages 113–114 and see Dr Perry – Day 58, page 16

<sup>161</sup> See Dr Foster – Day 56, pages 115–116

treatment (80°C/72hours) of the PFC's intermediate purity NY product (purified a little further) on the grounds that: (i) laboratory experiments had shown that the product could be freeze-dried and heated at high temperatures; and (ii) dry heating would be more straightforward than pasteurisation (both in terms of equipment and staffing) and could be fitted into the PFC's current manufacturing and staffing processes more easily.<sup>162</sup> Dr Cuthbertson shared Dr McIntosh's view for similar reasons, but also on the basis that dry heat treatment would take place in the final sealed container which would reduce the risk of cross-contamination.<sup>163</sup> Dr Cuthbertson also indicated that 8Y's apparent success in England was another factor in favour of dry heat treatment.<sup>164</sup> For his part, Dr Perry went into the meeting with an open mind. While dry heat treatment was likely to be the simpler route, he was conscious of the 'presentational issue' that early commercial dry-heated products, heated at lower temperatures, had not turned out to be safe. The dry heat treatment process had the potential to be discredited due to previous failures.<sup>165</sup>

**24.87** At the end of the meeting a decision was made to recommend the prioritisation of the severe dry heat treatment of PFC's intermediate purity product.<sup>166</sup> Dr McIntosh was to lead the development of the project and Dr Perry would inform Professor Cash, as head of the SNBTS, of the group's recommendation.<sup>167</sup>

**24.88** In his written evidence to the Inquiry, Dr Foster summarised the reasons for the PFC changing its Factor VIII strategy as follows:

- a pre-publication report from the USA [the Prince report noted above] which found HIV to be more resistant to dry heat treatment than earlier experiments had indicated ... leading to uncertainty over the margin of safety being provided by the current SNBTS dry heat treated Factor VIII concentrate,
- a problem of instability that had been identified on the scale-up of SNBTS high purity NYU Factor VIII product, which required to be solved,<sup>168</sup>
- difficulty in dry heating high purity Factor VIII product at 80°C,
- recognition that the sophisticated equipment required for the production of high purity Factor VIII could not be obtained quickly<sup>169</sup> and that its operation would require revised staffing arrangements, the establishment of which was uncertain,<sup>170</sup>
- that full scale production of 8Y had been achieved successfully at the BPL,
- that the 8Y produced at the BPL had been found to be satisfactory in terms of clinical efficacy and tolerability.<sup>171</sup>

<sup>162</sup> Dr McIntosh – Day 61, pages 49–51

<sup>163</sup> Dr Cuthbertson – Day 57, page 52. See also Dr Foster – Day 56, pages 115–116 who mentions that Dr McIntosh also made this argument, and that he considered it persuasive.

<sup>164</sup> Dr Cuthbertson – Day 57, pages 52–53

<sup>165</sup> See Dr Perry – Day 58, page 18; and, for a discussion of the 'presentational issue' pages 20–21. Dr Perry was also attracted to the fact that dry heat treatment would take place in the final container – see Dr Perry – Day 58, page 34

<sup>166</sup> See Dr Foster – Day 56, pages 116–117; Cuthbertson – Day 57, page 51; Dr Perry – Day 58, page 22 and Dr McIntosh – Day 61, pages 48–49

<sup>167</sup> Dr Foster – Day 56, page 117. It would appear that any such meeting would have had to have taken place in 1986 (see discussion of the events of 1986 below and Dr Perry – Day 58, page 22).

<sup>168</sup> The product became unstable when around 100 litres of plasma was used. This problem had not been solved by the time of the meeting on 23 December 1985. Dr Foster – Day 56, pages 96–97

<sup>169</sup> A delay of 6–9 months was likely: Dr Foster – Day 56, pages 97–98

<sup>170</sup> Shift-working: Dr Foster – Day 56, pages 97–98

<sup>171</sup> SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1351

1986

### Research on Z8 prioritised

**24.89** Although it appears to have been understood that Dr Perry and Professor Cash would meet in early 1986 to discuss the proposed new heat treatment strategy, the Inquiry has been unable to find any record of such a meeting and neither witness could recall such a meeting having taken place.<sup>172</sup> Despite that, in their evidence to the Inquiry, both Dr Perry and Professor Cash were of the view that such a meeting must have taken place some time at the start of 1986. Professor Cash indicated that the PFC would have required to discuss its proposed change of strategy with him as he was the ‘ultimate decision maker’ for the SNBTS.<sup>173</sup> Although there is a degree of uncertainty as to exactly when and how Professor Cash approved the proposed change of direction at the PFC, it seems highly likely that at some point in early 1986 Professor Cash must have approved the new strategy to develop an intermediate purity Factor VIII product that could be severely dry- heated.

**24.90** Dr Perry drew up a report for a meeting of the Haemophilia Directors in March 1986.<sup>174</sup> The report, dated 10 January 1986, mentioned the BPL’s 8Y product, indicating that, ‘preliminary clinical data indicates that this material is non-infective with respect to HTLV III, NANB and Hepatitis B’.<sup>175</sup> The report referred to the PFC’s NYU high purity product and noted that, ‘[A] programme of in-vitro characterisation and animal studies has been initiated and it is likely that the product will be ready for Phase I clinical studies in April 1986’.<sup>176</sup>

**24.91** No mention was made in Dr Perry’s report, however, of the decision made at the meeting on 23 December to prioritise the development of an intermediate purity Factor VIII product that could be severely dry-heated.

**24.92** When asked during the public hearings why the report did not mention that important change in strategy, Dr Perry suggested that the report may have been drawn up before he had had a chance to speak to Professor Cash, or that Professor Cash may have been away in January of 1986.<sup>177</sup> He considered it equally possible that the report was drafted in late 1985, before the meeting on 23 December had taken place.<sup>178</sup> Dr Perry further explained that the reference in his report to the high purity NYU product being ready for Phase I clinical trials in April 1986 was ‘perhaps an over-optimistic statement’ and that, in any event, any trials would have been of a pilot production scale product rather than a full production scale product.<sup>179</sup>

**24.93** It appears likely that Dr Perry was correct in speculating that his report was drafted before the meeting on 23 December 1985 and, because of the Christmas break, was not typed up until 10 January 1986.<sup>180</sup> In any event, the outcome of the meeting on 23 December

---

<sup>172</sup> Dr Perry – Day 58, page 22; Professor Cash – Day 57, pages 92–94

<sup>173</sup> Professor Cash – Day 57, pages 92–94

<sup>174</sup> Dr Perry’s report [SNB.001.5469]. The report was attached as Appendix VI to notes [SNB.001.5454] drawn up by Professor Cash in February 1986 for this meeting.

<sup>175</sup> Dr Perry’s report [SNB.001.5469] at 5472

<sup>176</sup> Dr Perry’s report [SNB.001.5469] at 5473

<sup>177</sup> Dr Perry – Day 58, pages 22–27

<sup>178</sup> Dr Perry – Day 58, page 24

<sup>179</sup> Dr Perry – Day 58, pages 32–33

<sup>180</sup> The report comments that it was unlikely that the current PFC Factor VIII product could be treated successfully at 80°C for 72 hours, a view Dr Perry was unlikely to have expressed after the meeting: Dr Perry’s report [SNB.001.5469] at 5472

was reflected in an addendum produced by Dr Perry to his report.<sup>181</sup> While the addendum is undated, it appears to have been sent to Professor Cash on either 25 January 1986 or 18 February 1986.<sup>182</sup> The addendum indicated that research had shown that the PFC's intermediate purity product could tolerate severe heat treatment and that:

This information will enable a non-infective product to be achieved using intermediate-purity material without compromising the development of the very high purity product ....<sup>183</sup>

**24.94** Various advantages of the new strategy were mentioned in the addendum including that it would allow: (i) non-infective product to be introduced more quickly and (ii) the high purity product to be properly assessed and phased in without undue haste (the implication being that work on the high purity product had not been completely abandoned).<sup>184</sup> It was also noted that it was likely that the intermediate dry heated product, 'will be available for evaluation in April 1986'.<sup>185</sup> When asked about this projection, Dr Perry said that it could have only been in relation to a product 'somewhere between laboratory and pilot scale manufacture' and that he must have written the addendum relatively early in 1986 as 'if [he] had been writing it in March' then his April estimate 'would have been wildly off course'.<sup>186</sup> Dr Foster also commented on the issue of the April 1986 evaluation date in his written statement to the Inquiry.<sup>187</sup> He advised that he had suggested this date to Dr Perry, but that it was incorrect because he had assumed that pilot scale material would be used for clinical trials as this had been the approach previously taken with the pasteurised ZHT product. However, in the event, trials were not carried out until full-scale production Z8 was available.<sup>188</sup> In addition, various unexpected problems occurred in the development and production of Z8 (as discussed at paragraph 24.125 below).<sup>189</sup>

**24.95** Although it is unclear when exactly a final management decision was taken to prioritise the severe dry heat treatment of the PFC's intermediate purity product, it is clear that the PFC continued research, led by Dr McIntosh, into this process at the start of 1986. The Inquiry recovered handwritten notes of experiments undertaken by him during January and February 1986.<sup>190</sup> A significant development was the introduction of ultra-filtration (in substitution for size-exclusion chromatography) in formulating the supernatant from the zinc-precipitated material to become a finished product.<sup>191</sup> The development of full scale ultra-filtration equipment for manufacturing purposes and the sequencing of production processes had occupied time and resources in 1985.<sup>192</sup> Freeze-drying equipment and procedures also presented difficulties.<sup>193</sup>

<sup>181</sup> Addendum to Dr Perry's report [SNB.001.5484]. The addendum appears intended to replace the Factor VIII information in the 'Development of New Products in 1986/7' section of the original 10 January 1986 report – ie [SNB.001.5469] at 5472

<sup>182</sup> See letter from Dr Perry to Professor Cash attaching report dated 25 January 1986 [SNB.001.5485] and a similar letter also attaching a report dated 18 February 1986 [SNB.001.5442]. Although this is unclear, it may be that the initial letter in January contained the first report [SNB.001.5469] and the letter in February the addendum.

<sup>183</sup> Addendum to Dr Perry's report [SNB.001.5484]

<sup>184</sup> Addendum to Dr Perry's report [SNB.001.5484]

It would have been necessary to purchase and install new equipment for large-scale size-exclusion chromatography, and PFC already had experience of ultra-filtration from work on ZHT: SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1352

<sup>193</sup> Dr McIntosh – Day 61, pages 58–59

**24.96** From February 1986 the change of direction at the PFC began to be recorded in contemporaneous documents. In his notes for the March 1986 meeting of the Haemophilia Directors and Transfusion Directors, for example, which were drawn up in February 1986, Professor Cash indicated that difficulties had arisen as regards the heat treatment of the high purity product and that:

As a consequence it is anticipated that there will be some delay in it reaching phase 1 (recovery and ½ [life]) studies. Accordingly, a decision has been taken to introduce an interim solution: a product which is only 2–3 times purer than the existing intermediate VIII but which can be dry heated at 80°C for 72 hours.<sup>194</sup>

**24.97** While this document is further evidence that work on the high purity product had not been abandoned completely, Dr Foster said that at this time Dr McIntosh was focusing almost entirely on severe dry heat treatment, rather than high purity work.<sup>195</sup> Dr Cuthbertson echoed this point. He said that the high purity process had been put ‘on the backburner’ and that even if there had been a desire to develop the high purity project rapidly there was insufficient assay capacity in his testing laboratory to focus on two research and development projects simultaneously in addition to routine testing of manufactured products for quality control.<sup>196</sup>

**24.98** During this period, contact with the PFL in England continued and, on 26 February 1986, Dr Smith wrote to Dr Duncan Pepper with details on what he described as ‘the last significant stage of 8Y’ as well as his thoughts on ‘very fast freezing’.<sup>197</sup> Freeze-drying was also discussed during a meeting of the SNBTS Coagulation Factor Study Group on 27 February 1986 in which mention was made by Dr Perry of plans for ‘improved freezing’ and improved freeze-drying of the intermediate purity product which was to be heated at 80°C for 72 hours.<sup>198</sup>

**24.99** At the meeting of Haemophilia Directors and SNBTS Directors on 5 March 1986, the switch to developing severe heat treatment of the intermediate purity product was discussed with the Haemophilia Directors.<sup>199</sup> It was at this stage, following a memorandum sent by Dr Foster to Dr Perry and Dr McIntosh dated 5 March 1986 that ‘Z8’ was selected as the name for the product (intended to be heated at 80°C for 72 hours).<sup>200</sup> Dr Foster had become concerned that the multiplicity of PFC Factor VIII products under consideration might cause confusion outside the PFC. He listed two ZHT products heated at 68°C, the 80°C product that was named Z8, and a fourth ‘PFC, NYU FVIII’, the high purity product on the ZHT base, which he proposed should be named ‘REAL 8’.

### Spring 1986 – work on Z8 continues

**24.100** Further work relating to the development of Z8 continued throughout the spring of 1986. A meeting took place at the PFC between individuals from the BPL and the SNBTS on 17 March 1986 at which the two organisations exchanged information about

<sup>194</sup> Professor Cash’s notes for meeting in March 1986 [SNB.001.5454] at 5459

<sup>195</sup> Dr Foster – Day 56, page 121

<sup>197</sup> Dr Smith’s letter to Dr Pepper of 26 February 1986 [SNB.007.5606]

<sup>198</sup> Minutes of Coagulation Factor Study Group meeting, 27 February 1986 [SNB.007.5596] at 5598 – this group was formerly known at the ‘Factor VIII Study Group’.

<sup>199</sup> Minutes of SNBTS and Haemophilia Directors meeting, 5 March 1986 [SNB.001.5448] at 5450

<sup>200</sup> Dr Foster’s memorandum of 5 March 1986 [SNB.007.5608]

progress in research and development and agreed further collaboration.<sup>201</sup> Discussion was summarised by Dr Perry in a note dated 24 March 1986.<sup>202</sup> During this meeting virus inactivation studies were discussed and it was agreed that the BPL would send samples of 8Y to the PFC, which had more specialist facilities, to carry out studies into levels of virus inactivation.<sup>203</sup> At the meeting Dr Smith outlined clinical trial results for 8Y. It was noted by Dr Perry that:

While results cannot be considered conclusive at this stage ... no cases of virus infection have occurred (attributable to 8Y material) after 12 months experience of 8Y in virgin haemophiliacs.<sup>204</sup>

**24.101** At the Inquiry's public hearings Dr Smith said that by March 1986 there was evidence that heating Factor VIII at 80°C instead of 60°C was beneficial as regards HIV.<sup>205</sup> However, as regards NANB Hepatitis he said that he considered that Dr Perry's summary of the March meeting relating to the perceived safety of 8Y was based probably on a very brief review of the facts and that it was too optimistic.<sup>206</sup> Dr Smith accepted that, logically, the preliminary results reported gave what he called 'a slightly larger margin of safety'. However he stressed that he was not of the view at the time that this could be viewed as significant statistically or that there was a 'high probability of the product being safe'.<sup>207</sup> While initial results from its use suggested that 8Y had a greater margin of safety in respect of the transmission of NANB Hepatitis, Dr Smith was of the opinion that there was insufficient evidence of freedom from infection in 1986 to enable any robust scientific conclusions to be made.<sup>208</sup>

**24.102** Dr Foster was asked about his knowledge of the clinical results for 8Y at this period.<sup>209</sup> He said that he was aware of the general view that the clinical trial of 8Y was proceeding well,<sup>210</sup> but that he was not specifically kept up to date with the emerging clinical data available from the routine use of 8Y. He would have expected Dr Smith to inform him of any bad news, and the lack of any such news was reason for cautious optimism.<sup>211</sup>

**24.103** At the BPL/SNBTS meeting on 17 March 1986 mentioned above, there was also discussion of the likelihood that freeze-drying conditions might affect the efficacy of heat treatment.<sup>212</sup> On 24 March 1986 Dr Foster received further details of the freeze-drying cycles for BPL's Factor VIII and Factor IX products as requested.<sup>213</sup>

<sup>201</sup> The Advisory Committee on the Virological Aspects of the Safety of Blood Products had recommended on 7 February 1986 that a working group should be established between the BPL, Elstree, the PFC, Edinburgh and NIBSC, which would meet periodically and provide a forum for the exchange of technical and scientific information pertaining to the safety of blood and blood products, especially in relation to virus contamination and the evaluation of manufacturing procedures to inactivate or eliminate viruses: Minutes of 7 February 1986 meeting [SNB.005.1495] at 1508.

<sup>213</sup> Letter from Mr Kinnarney (BPL) to Dr Foster, dated 19 March 1986, received at PFC on 24 March 1986 [PEN.017.1399]

**24.104** Between March and May 1986 work on developing Z8 continued. Dr McIntosh indicated that during this period the PFC was involved in ‘further work on freeze-drying and on the formulation of the ultra-filtered material’.<sup>214</sup> The scale-up of the ultra-filtration stage in preparation for Z8 manufacture was a large part of this work and would have involved familiarising staff with new ultra-filtration equipment.<sup>215</sup> On 25 April 1986, the first virus inactivation experiments were performed on samples of Z8 produced in the research laboratory and dry-heated at 80°C.<sup>216</sup>

**24.105** Steps were also underway at the PFC to carry out virus inactivation experiments on 8Y on behalf of the BPL. On 9 May 1986, for example, Dr Cuthbertson sent Dr Lane of the BPL an outline of the protocol (using model viruses) which the PFC intended to use in evaluating virus kill in 8Y.<sup>217</sup>

**24.106** In May 1986, Drs Cuthbertson, McIntosh and Foster of the PFC presented a paper at an international conference in Sydney, Australia. A summary of the paper emphasised the importance of freeze-drying for successful heat treatment, noting that:

During heating in the freeze dried state we have noted that the stability of FVIII and FIX concentrates is influenced profoundly by changes to freeze drying conditions and product formulation. Unfortunately these parameters have been omitted from publications concerning virus inactivation, making it impossible to properly interpret results and their relevance to manufacturing procedures.<sup>218</sup>

#### Pilot-scale production of Z8 and plans for clinical trials

**24.107** On 23 June 1986 the first pilot scale production of Z8 (80°C for 72 hours) was carried out at the PFC using around 200 litres of plasma.<sup>219</sup>

**24.108** At this time, efforts were also under way in relation to setting up clinical trials and planning for the introduction of new heat-treated products as they became available. On 27 June 1986 Dr Boulton wrote to Professor Cash indicating that:

I have again spoken to Christopher Ludlam who continues to assert his willingness to participate in studies of new factor VIII materials for patients, both virgin and multi-transfused.

Apparently a few weeks ago he was asking Brian McClelland if VIIIY<sup>220</sup> could be made available in the event of a ‘virgin’ haemophiliac being presented. He tells me that he would be happy to treat such patients with a product prepared by the SNBTS that has been subjected to an ‘equivalent’ heat-treatment regime.<sup>221</sup>

<sup>220</sup> ‘VIIIY’ refers to the English product 8Y.

<sup>221</sup> Dr Boulton’s letter to Professor Cash of 27 June 1986 [SNB.007.5869]

**24.109** Professor Cash responded to Dr Boulton's letter on 1 July 1986, explaining that:

You may be under some misunderstanding with regard to the type of studies we require. I can best emphasise the point by stating that we have already agreed that until such times as we have a product which is to be the definitive product for at least 5 years we won't consider further the awesome task of a NANB study on virgin haemophiliacs. In the meantime we will require to consider ½ life and in vivo recovery studies (on small numbers of non-virgin patients) ....<sup>222</sup>

**24.110** On 2 July 1986, Dr Perry wrote to Dr Boulton intimating that the PFC was poised to launch another Factor VIII product, heated at 80°C for 72 hours (Z8), which, he said, 'should therefore be comparable to 8Y' and better than anything available commercially. The comment was clearly intended to respond to Dr Boulton's letter dated 27 June (paragraph 24.108). Dr Perry suggested that virgin haemophilia patients might have access to this product before the stocks of existing products were exhausted, though that had not been formally agreed.<sup>223</sup> Dr Boulton was prompted to ask about PFC's plans, and a telephone conversation ensued.

**24.111** On 4 July 1986 Dr Boulton wrote to Dr Perry enclosing notes of the projected production sequence as he understood it from the telephone conversation between them.<sup>224</sup> Dr Perry responded to Dr Boulton's letter on 7 July 1986, adjusting some of the detail recorded.<sup>225</sup> Full scale production of Z8 was expected to begin in September 1986. Half life and recovery studies on 'non virgin' haemophilia patients would be required between September and December 1986. It was planned to begin production of the PFC's high purity NYU product (which Dr Foster proposed to name 'REAL 8') in January 1987 with supply in September 1987 after stocks of Z8 had been used up. On this projection there would be no PFC product virucidally comparable to the BPL's 8Y until September 1986. Dr Perry intended to supply Z8 for 'virgin' patients from September 1986, removing the need to 'go south' for such patients. In the immediate future, until September 1986, he thought that they could probably get supplies of 8Y for special cases, and expressed the view that it would be preferable to obtain and supply English material through the PFC. At this stage production of Z8 was still seen as an interim measure with the development of a high purity Factor VIII product continuing as the eventual aim.

**24.112** On 28 July 1986 production of the second pilot scale preparation of Z8 was carried out.<sup>226</sup>

**24.113** On 30 July 1986 a meeting of a steering group, 'New FVIII Product Manufacture', took place which decided that no further 'old-style FVIII' (ie the 68°C/24 hours product) would be made for the time being and noted that a large-scale production run of the new Z8 product had been approved to take place on 4 August 1986.<sup>227</sup> The cessation of 68°C/24 hours production and the date for the first large-scale run of Z8 were both a little earlier than Dr Perry had forecast in his discussion with Dr Boulton.

<sup>222</sup> Professor Cash's letter to Dr Boulton of 1 July 1986 [SNB.005.1522]

<sup>223</sup> Dr Perry's letter to Dr Boulton of 2 July 1986 [SNB.007.5909]

<sup>224</sup> Dr Boulton's letter to Dr Perry of 4 July 1986 [SNB.007.5910] and his note of their telephone conversation [SNB.007.5911]

<sup>225</sup> Dr Perry's letter to Dr Boulton of 7 July 1986 [SNB.007.5913]

<sup>226</sup> Preparation of Improved Intermediate Purity FVIII (Z8) – Batch No: Z8-5-002 [SNB.007.9049]

<sup>227</sup> Notes of New FVIII Product Manufacture Steering Group meeting, 30 July 1986 [SNB.007.9072]

**24.114** Dr Perry said that the routine manufacture of NYFVIII (68°C/24hr) was discontinued in July 1986 to allow the the PFC to focus its development and manufacturing resources on the final development stages of Z8 with a view to building up working stocks of Z8 for distribution through the batch dedication system. At this point it was estimated that sufficient stocks of NYFVIII were available to meet planned requirements until the spring of 1987, which was therefore the estimated date for the transition from NYFVIII to Z8.<sup>228</sup>

**24.115** In his briefing paper on the development of heat treatment, Dr Foster stated that:

By July 1986, progress in the pilot studies was encouraging and there were good stocks of existing 68°/24-hour heat-treated Factor VIII concentrate available. It was therefore decided to cease production of the existing product to release production staff and facilities in order to fast track the development of Z8 at large scale. Preparation of the first production trial batch of Z8 was begun in August 1986.<sup>229</sup>

**24.116** Dr Perry explained that PFC's production strategy was based on a phased development plan involving the progressive development and introduction of heated products, without interruption of supply. The strategy required that the PFC should continue to routinely manufacture NYFVIII (68°C/24hr) until the Z8 product had been developed, validated at scale, transferred to routine production, and safe working stocks established.<sup>230</sup>

**24.117** Dr Perry further explained the rationale behind the switch to Z8 production in the summer of 1986 indicating that, 'we had a high level of confidence that we were on the right track. We had a very high level of expectation that the development would be successful within the sort of timescales that we had established'.<sup>231</sup>

**24.118** At the Inquiry hearings these comments were echoed by Dr McIntosh who said that, 'production of the previous product, NY [heated at 68°C for 24 hours], had been suspended or halted, to give us full access to production, and a decision was made to prepare material [ie Z8] at as large a scale as possible but for experimental purposes'.<sup>232</sup>

**24.119** In mid-1986, therefore, the SNBTS's priority project was the production of Z8, considered to be 'virucidally equivalent' to the BPL's 8Y, as an interim solution to the transmission of virus infection, retaining the longer term objective of developing a superior pasteurised product. It was implicit in the development process that trials would be required of successive products, at least for half-life and in vivo recovery. Apart from the difficulties inherent in the development and production of effective products, there was growing resistance from haemophilia clinicians to exposing their patients to trials without adequate insurance against adverse reactions. It is important to set Scottish experience at this time in a wider context.

---

<sup>228</sup> Dr Perry's statement on Viral Inactivation, 1985–87 [PEN.017.1219] at 1223

<sup>229</sup> SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1353

<sup>230</sup> Dr Perry's statement on Viral Inactivation, 1985–87 [PEN.017.1219] at 1223. Dr Perry admitted during the Oral Hearing that, as the 68°C/24hr product was stopped in July 1986 when Z8 was only at the pilot scale, this statement was not completely correct – see Dr Perry – Day 58, page 44

<sup>231</sup> Dr Perry – Day 58, page 45

<sup>232</sup> Dr McIntosh – Day 61, page 57

**24.120** In June 1986, the World Hemophilia Federation Conference was held in Milan. Dr Smith attended and produced notes. A copy was available in Scotland.<sup>233</sup> Reports of the discussions of a range of products underlined doubt about their effectiveness. Armour's product Factorate, issued before January 1986, was withdrawn in July 1986. Other heat-treated products such as Travenol (60°C for 72 hours) and Cutter (68°C for 72 hours) were not withdrawn, but were gradually replaced in the period after 1 January 1987. It seems likely that this development was prompted primarily by the search for a form of viral inactivation effective against the risk of transmission of NANB Hepatitis, although general misgivings about the effectiveness against the risk of transmission of HIV of dry heat treatments at temperatures in the region of 60°C may have contributed to the development.

**24.121** Pasteurised products began to appear. Alpha Profilate was a heat-treated, wet method product, heated at 60°C for 20 hours. Armour were licensed in the USA to market Haemate P, the pasteurised heat-treated Factor VIII developed by Behringwerke. Cutter was licensed to manufacture Koate HS, a heat-treated pasteurised product. The wider, worldwide, market appeared to have been moving towards pasteurised products at this time, though further change was imminent. On 21 July 1986, Immuno distributed a circular intimating that dry-heated products had been discontinued: all products would be subject to steam treatment for the future, and that included FEIBA. This was a period of considerable uncertainty worldwide. Developments in Scotland have to be seen in that light. Retaining the option of pasteurisation while prioritising dry heat treatment was not out of line with international developments.

**24.122** As approved on 30 July (paragraph 24.113), the first large-scale production run of PFC Z8 took place on 4 August 1986.<sup>234</sup> On 7 August 1986 satisfactory viral inactivation studies were carried out comparing the effects of heating Z8 at 75°C and 80°C on model viruses.<sup>235</sup> On the same day Dr Perry wrote to Dr Boulton indicating that two batches of Z8 (the pilot-scale batches, prepared in June and July 1986)<sup>236</sup> had been successfully manufactured and noting that, 'assuming all is well on the QA front, we are well on target to make product available for clinical trial end of August/beginning of September'.<sup>237</sup> He said that discussions could start with Professor Ludlam regarding clinical trials of Z8. In the event, as noted below at paragraph 24.131, early production batches could not stand heating at 80°C and were heated at 75°C until January 1987 and released for use.<sup>238</sup> Around this time Dr Smith passed to Dr Foster a memo outlining changes to the freeze-drying regime for 8Y.<sup>239</sup>

**24.123** On 20 August 1986 a meeting of the CSA Blood Transfusion Service Sub-Committee took place at which the issue of 'compensation of volunteers' was discussed.<sup>240</sup> The minutes of the meeting noted that the National Medical Director (Professor Cash)

<sup>233</sup> Dr Smith's report on XVIII Congress of the World Federation of Hemophilia, 1986 [SNB.007.5955]. The document is contained in contemporaneous SNBTS files. It was probably provided to Dr Foster in accordance with their practice of exchanging reports of conferences: See Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*, paragraph 23.80

<sup>240</sup> Minutes of CSA Blood Transfusion Service Sub-Committee, 20 August 1986 [SGH.002.0455] at 0456

had had ‘a useful dialogue with the Legal Adviser concerning arrangements for the compensation of volunteers and agreed that the General Manager [of the CSA] should now pursue the bringing forward of firm proposals’.<sup>241</sup>

**24.124** On 22 August Dr Boulton wrote to Dr Perry enquiring as to the availability of the Z8 product and wondering how to approach Professor Ludlam to conduct in vivo half-life and survival studies.<sup>242</sup>

### An eleventh-hour problem

**24.125** Dr Perry responded to Dr Boulton’s letter on 29 August 1986, explaining that:

While we now have material which can be used for trial (beginning September) in Dr Ludlam’s patients, I am not, at this stage, convinced that it has a proper GMP [Good Manufacturing Practice] pedigree or that it represents our definitive process. We have recently encountered an eleventh hour problem with freeze-drying which we are now addressing with some considerable urgency. The result of this is that we will not be able to meet the target dates of early September for clinical trials.<sup>243</sup>

**24.126** In his briefing paper Dr Foster explained that the ‘eleventh hour problem’ resulted from the switch from pilot-scale production to full-scale production. While only a small number of vials of Z8 had been produced in each pilot batch, the number of vials produced by full-scale production completely filled the freeze-dryer. That affected the conditions in the freeze-dryer with the result that a significant number of vials failed to withstand 80°C dry heating.<sup>244</sup>

**24.127** It was observed that vials with frozen plugs of a uniform, fine crystal structure could withstand dry heating to 80°C, whereas those with larger crystals or a mixture of fine and large crystals did not withstand heating to that temperature.<sup>245</sup> Dr Foster explained that as differences in crystal structure are determined by the rate of freezing it was postulated that the uniform formation of fine crystals in the vials which had survived heating might be the result of ‘super-cooling’, a condition at which the vial contents remain liquid below the freezing point of the solution. In this situation a small disturbance in the fluid is sufficient to cause instantaneous crystal formation resulting in fine crystals.<sup>246</sup>

**24.128** On 25 September 1986 Dr McIntosh carried out further experiments using a production-scale dryer in order to investigate the super-cooling hypothesis, following which he concluded that super-cooling had, indeed, occurred.<sup>247</sup> Efforts then followed to develop a freeze-drying cycle which, in the words of Dr McIntosh, ‘would induce supercooling ... in a reproducible way and in a uniform way across the batch’.<sup>248</sup> This was reported in a meeting of the PFC Development Review Group of 15 October 1986 where

<sup>241</sup> Ibid [SGH.002.0455] at 0456

<sup>246</sup> SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1354

<sup>247</sup> SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1354; Dr McIntosh – Day 61, pages 61–62; and Dr Foster – Day 56, page 141. For the notes of these experiments see [PEN.017.1434].

<sup>248</sup> Dr McIntosh – Day 61, page 61

it was noted that the Z8 process 'requires further developments in formulation and freeze drying to enable heating at 80°C/72hr to be achieved reproducibly'.<sup>249</sup>

**24.129** On 14 October 1986 a further meeting of the SNBTS Coagulation Factor Study Group took place. The minutes of the meeting included an update on Z8 and a summary of steps taken in respect of its 'Introduction to Routine Production'.<sup>250</sup> The summary explained that heating to 80°C/72 hours of various lots of Factor VIII in a full-scale, large-production dryer had resulted in losses of Factor VIII activity ranging from 30% to 70%. It was noted that:

Failure at full scale production was due to varying performance of the freeze drier and a change in product composition .... In an effort to overcome these problems work was continuing in the following areas:

1. Modifications to procedure to improve extraction.
2. Establishment of freeze drying parameters to cope with 'worst case scenario.'
3. Reduction of weight of cryo/L plasma to 1984 levels.<sup>251</sup>

**24.130** Dr Foster reviewed the Z8 studies undertaken, including the efforts made to overcome the difficulties with the performance of the freeze dryer. Heating at 75°C for 72 hours was reported. It was thought that there were difficulties in the production and issue of a product heated to 75°C/72 hours and it was agreed that Professor Cash would write to Dr Boulton seeking the co-operation of the Haemophilia Directors in undertaking a small study of recovery and half-life of this product.<sup>252</sup>

**24.131** In the light of this meeting, Professor Cash indicated to Dr Perry in a letter dated 15 October 1986 that it was appropriate for the PFC to commence production of a 75°C/72 hours dry-heated product, while continuing to work on the development of an 80°C/72 hours product.<sup>253</sup> According to Dr McIntosh, the decision to try to release a product heated to 75°C first was due to the fact that the PFC had not yet been able to develop a product with a crystalline structure which could tolerate heating at 80°C.<sup>254</sup> Given this, the PFC was of the view that heating to 75°C (which was achievable) would be a suitable interim solution and was an improvement on the existing 68°C/24 hours dry-heated Factor VIII.<sup>255</sup>

**24.132** On 13 November 1986 Professor Cash wrote to Dr Boulton explaining the plan to commence production of 'a new factor VIII concentrate which will be called Z8' and which 'will be dry heat treated at 75°C for 72 hours'.<sup>256</sup> The letter asked Dr Boulton to 'liaise with Chris Ludlam, Charles Forbes and Elizabeth Mayne with a view to obtaining t/2 and % recovery data on the product'.<sup>257</sup> This was followed by a letter from Dr Cuthbertson to

<sup>249</sup> Notes for Development Review Group meeting, 15 October 1986 [SNB.006.7564] at 7564. According to Dr McIntosh – Day 61, page 63 – the reference to 'developments in formulation' refers primarily to increasing the 'ionic strength' (ie salt content) of Z8.

<sup>254</sup> Dr McIntosh – Day 61, page 67

<sup>255</sup> Ibid

<sup>256</sup> Professor Cash's letter to Dr Boulton of 13 November 1986 [SNB.007.6241]

<sup>257</sup> Professor Cash's letter to Dr Boulton of 13 November 1986 [SNB.007.6241]. Professor Ludlam was the Haemophilia Director in Edinburgh. Dr Forbes and Dr Mayne were his counterparts in Glasgow and Belfast respectively (see: Dr Cuthbertson – Day 57, page 59).

Dr Boulton on 26 November 1986 enclosing a copy of the draft specification for Z8.<sup>258</sup> On 1 December 1986 Dr Perry noted, during a Clinical Trial Review meeting, that the 75°C/72 hours product was now available for half-life and recovery studies in Edinburgh, Glasgow and Northern Ireland and that Dr Boulton was coordinating this study.<sup>259</sup> On 1 December Dr Boulton wrote to Dr Perry, acknowledging receipt of Professor Cash's letter and the Z8 specification; and explaining that he wished to supply Professor Forbes in Glasgow directly with the product rather than following the usual course of sending the product via Law BTS.<sup>260</sup> On 12 December 1986 Dr Crawford of the Glasgow and West of Scotland Blood Transfusion Service (Law Hospital) wrote to Dr Perry expressing a degree of disquiet as regards the possible direct transfer and asking Dr Perry to contact Dr John Davidson (Glasgow Royal Infirmary, haematology laboratory)<sup>261</sup> with a note of any Z8 supplied to Professor Forbes.<sup>262</sup> Dr Perry passed on this message to Dr Boulton in a letter dated 23 December 1987 and asked Dr Boulton to contact Dr Davidson 'with a note of that material which will be issued to Charles Forbes ... when you know how much to send to Dr Forbes'.<sup>263</sup>

**24.133** According to PFC records, the first clinical grade batch of the 75°C/72 hours product was 'placed at issue' (ie certified as fit for clinical use)<sup>264</sup> on 2 December 1986,<sup>265</sup> the batch in question having been manufactured in October 1986 and then having undergone standard quality control procedures.

**24.134** Towards the end of 1986 research was continuing at the PFC into improving freeze-drying techniques. On 16 December 1986 Dr Foster wrote to Dr Smith indicating that the PFC had been involved in 'intensive work on freezing and freeze drying over the last 3 months' and that two problems had arisen when scaling up the Z8 process, namely: (i) the large production dryer performed differently to the small production and pilot dryers; and (ii) variations in final product total protein had arisen which had led to major batch-to-batch differences in solubility.<sup>266</sup> There were also substantial differences within batches when product was heated to 80°C. The letter explained that the PFC believed that they had now overcome all of these problems by means of a special freezing technique and by designing the freeze-drying cycle more carefully. The technological solution, which involved super-cooling to ensure an amorphous crystalline structure, was a so-called '2-stage freezing process'.<sup>267</sup>

**24.135** On 8 December 1986, Dr Smith sent Dr Foster, on a confidential basis, a paper on the effects of plasma conditioning on subsequent cryoprecipitation and cryoextraction.<sup>268</sup>

<sup>258</sup> Dr Cuthbertson's letter to Dr Boulton of 26 November 1986 [SNB.007.6268]

<sup>259</sup> Note of Clinical Trial Review meeting, 1 December 1986 [SGH.001.6672] at 6675

<sup>260</sup> Dr Boulton's letter to Dr Perry of 1 December 1986 [SNB.007.6270]. See also Dr Cuthbertson – Day 57, pages 60–61 for a description of the usual method of supply to Glasgow via Law BTS and Dr Perry – Day 58, pages 83–85 for further discussion as regards this letter.

<sup>261</sup> See Dr Cuthbertson – Day 57, page 67 for confirmation of John Davidson's position.

<sup>262</sup> Dr Crawford's letter to Dr Perry of 12 December 1986 [SNB.007.6298]. For discussion of this letter see Dr Perry – Day 58, page 79; and Dr Cuthbertson – Day 57, pages 66–67

<sup>263</sup> Dr Perry's letter to Dr Boulton of 23 December 1986 [SNB.007.6312]

<sup>264</sup> For more details on the meaning of 'placed at issue' see Dr Cuthbertson – Day 57, pages 62–63

<sup>265</sup> Batch issue history document [PEN.017.1437]; and Dr McIntosh – Day 61, pages 68–69 and Dr Cuthbertson – Day 57, page 62 (Drs McIntosh and Cuthbertson confirmed that PFC Factor VIII had an expiry date two years from the date of filling and that therefore the reference to a expiry date of October 1988 meant that manufacture must have been in October 1986).

<sup>266</sup> Dr Foster's letter to Dr Smith of 16 December 1986 [SNB.007.6296]

<sup>267</sup> According to Dr Foster's letter, this involved the following process, '[P]re-cool the shelf to -10°C; load the drier then leave the vials with the shelf controlled at -10°C for 1 hour (the Z8 product supercools to about -6°C within 30 minutes) ... then drop the shelf to -50°C 1 hour after loading and proceed as usual': Dr Foster's letter to Dr Smith of 16 December 1986 [SNB.007.6296] at 6297. See also SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1354

<sup>268</sup> Dr Smith's letter to Dr Foster of 8 December 1986 [SNB.007.6275] and paper on plasma conditioning [SNB.007.6276]

He explained that the 8Y process reflected know-how not yet 'sewn up' by patent. The studies based on information from empirical observations by Scottish scientists now had a measure of analytical support and theoretical underpinning. Dr Foster said as much in a reply dated 16 December 1986.<sup>269</sup>

**24.136** By the end of December 1986 the 75°C/72 hours product was released to Dr Boulton for distribution to centres participating in the clinical trial. On 22 December Dr Perry sent a memorandum to Dr Cuthbertson headed 'Z8 for clinical trial', in which he asked Dr Cuthbertson to 'send 200 vials of the selected batch to Dr Boulton who will subsequently distribute it to participating Centres'.<sup>270</sup> Twenty units of the product were issued on 22 December 1986, and a further 180 units were released on 24 December.<sup>271</sup>

**24.137** At a meeting of the Z8 steering group on 22 December 1986 it was noted that 'all batches manufactured in 1986 will be heated at 75°C/72 hours with 20 vials from each batch being heated at 80°C/72 hours'.<sup>272</sup> At this point, the two-stage freezing process had also been used successfully to manufacture certain batches of Z8 at 80°C/72 hours. There was a partial release for clinical trial of a batch of 80°C/72 hours product, manufactured in December 1986,<sup>273</sup> in February 1987.<sup>274</sup>

### Compensation for clinical trials

**24.138** On 5 December 1986 Dr Boulton wrote to Professor Cash noting that he had received the specifications of Z8 and had discussed the situation with Professor Ludlam who 'still has some reservations'. Professor Ludlam was concerned about patients who suffered as a result of being infused with the trial material and Dr Boulton felt he would be unwilling to agree to trials without a specific commitment by the SHHD to compensate them.<sup>275</sup> This was followed by a letter from Professor Ludlam to Professor Cash on 11 December 1986 which indicated that Professor Ludlam had 'obtained ethical approval to undertake recovery and survival studies in haemophiliacs' but was 'awaiting an appropriate commitment from either the PFC, the SHHD or the DHSS concerning the question of indemnity'.<sup>276</sup> The letter also commented that Professor Ludlam had 'raised this a long time ago with the SHHD and there [had] been no response' and that there was 'great disquiet' about this issue among colleagues at other Haemophilia Centres.<sup>277</sup> On 30 December 1986 Professor Cash telephoned Dr Archibald McIntyre of the SHHD and followed this up with a letter in which he stated that he would very much appreciate a formal response from the SHHD that patients receiving coagulation factor concentrates as part of a trial would receive compensation in the same way as 'blood donors who undergo immunisation/boosting for the procurement of anti-Rh (D) immune plasma'.<sup>278</sup>

<sup>269</sup> Dr Foster's letter to Dr Smith of 16 December 1986 [SNB.007.6296]

<sup>273</sup> Batch issue history document [PEN.017.1470]; Dr McIntosh – Day 61, page 69; Dr Cuthbertson – Day 57, page 69. The reference to an expiry date of December 1988 meant that manufacture must have been in December 1986.

<sup>274</sup> Batch issue history document [PEN.017.1470] refers to the release of 50 units of product to Edinburgh on 11 February 1987; and Dr Cuthbertson – Day 57, pages 69–70

<sup>275</sup> Dr Boulton's letter to Professor Cash of 5 December 1986 [SNB.007.6274]

<sup>276</sup> Professor Ludlam's letter to Professor Cash of 11 December 1986 [SNB.005.8711]. Professor Ludlam confirmed in his oral testimony that the term 'indemnity' was misleading and that the real issue was one of compensation for patients, not an indemnity for clinicians should a patient be harmed by a clinical trial. See Professor Ludlam – Day 58, pages 107–108

<sup>277</sup> Professor Ludlam's letter to Professor Cash of 11 December 1986 [SNB.005.8711]

<sup>278</sup> Professor Cash's letter to Dr McIntyre of 30 December 1986 [SGH.003.1919]. See also internal minute dated 30 December 1986 to Mr Murray [SGH.003.1920]. The reference to 'anti-Rh (D) immune plasma' refers to a group of 12 blood donors in Inverness whose blood was used to produce Anti-D for rhesus negative mothers in Scotland whose babies could be susceptible to Rhesus D Haemolytic Disease of the Newborn (ie Rh disease). See Professor Cash – Day 57, pages 108–109

1987

**24.139** The issue of compensation for clinical trials of Z8 continued into 1987. On 5 January Professor Ludlam wrote to Professor Cash explaining that he was ‘unwilling to test further blood products on patients’ until he received ‘written assurance that appropriate compensation will be available’.<sup>279</sup> The letter further noted that the SHHD had known of Professor Ludlam’s concerns since 1983; that ‘in such a serious matter more than verbal assurances are essential’; and that Professor Ludlam would be delighted to resume testing once he received ‘written assurance from an appropriate authority’.

**24.140** On 7 January 1987, Professor Cash sent a copy of Professor Ludlam’s letter to Dr McIntyre of the SHHD.<sup>280</sup> He also responded to Professor Ludlam directly, assuring Professor Ludlam of his ‘fullest support on this matter’, but emphasising that since existing Factor VIII (68°C/24 hours) would become exhausted ‘some time in February 1987’ it would be helpful for Professor Ludlam to respond to the following questions:

Given written (SHHD) assurance that appropriate compensation will be available to patients/relatives in the context of clinical assessment of Z8:

(a) Would you be prepared to use your best efforts to undertake recovery and t/2 life studies as quickly as possible, bearing in mind the PFC supply position?

(b) If Z8 proved to have acceptable recovery/t/2 life and there were no untoward (clinical) effects in the patients studied in (a) above would you be prepared to use Z8 immediately thereafter for routine clinical purposes?

(c) If time runs out on us (i.e. we can’t complete the Z8 in vivo recovery/t/2 studies before PFC stocks of factor VIII are exhausted) is it your intention to ask the Lothian Health Board to purchase product or would you prefer us to start up (if possible) the old intermediate (NY) factor VIII process again and thus maintain a no change position?<sup>281</sup>

**24.141** On the same date, Professor Cash wrote to the Scottish Haemophilia Centre Directors enclosing a copy of Professor Ludlam’s letter of 5 January 1987 and his response and asked them whether they were of the same view as Professor Ludlam.<sup>282</sup>

**24.142** Professor Ludlam responded to Professor Cash’s letter on 9 January 1987 explaining that given written assurance from the SHHD as regards compensation he ‘would be happy to organise immediately the appropriate infusion studies’ but that if Z8 was initially released on a ‘named patient basis’ he would require that the SHHD ‘extends its indemnity until a product licence is obtained’.<sup>283</sup> Professor Ludlam also indicated that if there was a delay in releasing Z8 before PFC stocks of Factor VIII ran out he would favour a return to ‘the old intermediate (NY) factor VIII’.<sup>284</sup>

**24.143** Meanwhile, an internal SHHD minute from Mr Alexander Murray dated 12 January 1987 explained that stocks of the existing Factor VIII product (NY) would

<sup>279</sup> Professor Ludlam’s letter to Professor Cash of 5 January 1987 [SGH.003.1911]

<sup>280</sup> Professor Cash’s letter to Dr McIntyre of 7 January 1987 [SGH.003.1907]. See also internal memo dated 7 January 1987 from Dr Forrester [SGH.003.1912] and the accompanying statement from Professor Cash [SGH.003.1913]

<sup>281</sup> Professor Cash’s letter to Professor Ludlam of 7 January 1987 [SGH.003.1980]

<sup>282</sup> Professor Cash’s letter to Scottish Haemophilia Directors of 7 January 1987 [SGH.003.1908]

<sup>283</sup> Professor Ludlam’s letter to Professor Cash of 9 January 1987 [SNF.001.3020]

<sup>284</sup> *Ibid* [SNF.001.3020]

shortly be exhausted, that a new Factor VIII product (Z8) had been developed but that the Haemophilia Directors had refused to carry out clinical trials on the new product unless suitable compensation arrangements were in place in respect of patients who suffered harm from the product.<sup>285</sup> Mr Murray explained that the DHSS faced a similar problem with the English Haemophilia Directors in respect of heat-treated Factor VIII produced by BPL. Mr Murray had alerted the Treasury (who would require to fund or agree to SHHD funding any compensation scheme) of the difficulties and to the fact that the SHHD would be making an approach to them. There then followed correspondence on the question of clinical trials between the SHHD, the DHSS and the Treasury.<sup>286</sup>

**24.144** On 13 January 1987, Drs Bruce Bennett and Audrey Dawson (Haemophilia Directors, Aberdeen Royal Infirmary) replied to Professor Cash's letter of 7 January indicating that they shared Professor Ludlam's view that the SHHD should give written assurance on compensation before the Z8 trial began.<sup>287</sup> Similarly, on 15 January 1987 Dr Heppleston phoned Professor Cash to indicate that the Haemophilia Directors in Dundee would also require SHHD assurance in respect of compensation.<sup>288</sup> Professor Ian Hann of the Royal Hospital for Sick Children (Yorkhill, Glasgow) responded to Professor Cash on 19 January 1987 noting that he agreed with Professor Ludlam that 'as usual the administrative process here has dragged on for too long' and that he believed strongly that children should not be used in the trials, 'especially as I do not know what Z8 is'.<sup>289</sup>

**24.145** Professor Ludlam's letter of 9 January appeared to have given Professor Cash some confidence as to the timeframe for the introduction of Z8 and on 13 January 1987 Professor Cash advised Professor Ludlam that:

Right now, assuming SHHD deliver the necessary assurances, we'll keep your team in reserve to test the 80°C/72 hours material which will very soon be with us. In the meantime Charles Forbes has agreed to look at the 75°C/72 hours product.

All being well we should just slip past the rocks I felt some days ago we were destined to founder on.<sup>290</sup>

**24.146** By letter dated 5 February 1987 the Treasury confirmed to the DHSS and the SHHD that it agreed that arrangements for compensation along the lines of the Association of the British Pharmaceutical Industry (ABPI) procedures could apply to clinical trials of heat-treated Factor VIII product.<sup>291</sup> Mr Murray advised Professor Cash of that by letter dated 6 February 1987.<sup>292</sup>

<sup>285</sup> Mr Murray's minute to Mr Kernohan of 12 January 1987 [SGH.003.1883]

<sup>286</sup> See DHSS letter to the Treasury dated 12 January 1987 [SGH.003.1891]; the Treasury's initial response dated 12 January 1987 [SGH.003.1890]; letter dated 14 January from SHHD to the Treasury [SGH.003.1881]; and letter dated 4 February 1987 from the Scottish Office Finance Division to the Treasury [SGH.003.1873].

<sup>287</sup> Drs Bennett and Dawson's letter to Professor Cash of 13 January 1987 [SNB.005.8713]

<sup>288</sup> Note of telephone conversation [SNF.001.3024] and Professor Cash – Day 57, page 113

<sup>289</sup> Dr Hann's letter to Professor Cash of 19 January 1987 [SNB.005.8712]

<sup>290</sup> Professor Cash's letter to Professor Ludlam of 13 January 1987 [SNF.001.3022]. In his oral evidence, Professor Cash confirmed that his reference to 'slipping past the rocks' related to fact that it appeared that the clinical evaluation and supply of Z8 would be possible before stocks of the 68°C/24 hours product ran out. See Professor Cash – Day 57, pages 111–112.

<sup>291</sup> Letter from Treasury to DHSS and SHHD, 5 February 1987 [SGH.003.1871]

<sup>292</sup> Mr Murray's letter to Professor Cash of 6 February 1987 [SGH.003.1870]

**24.147** On 11 February 1987 Professor Cash responded to Mr Murray's letter indicating that he was 'delighted with the news', but also noting that Mr Murray:

[M]ight also wish to consult with Duncan McNiven<sup>293</sup> [*sic*] as he will be aware of the particular point made by the haemophilia Directors, with regard to their perceived need for cover during the period a product is being made available for patient treatment on a named patient basis.<sup>294</sup>

**24.148** The mention of the Haemophilia Directors in Professor Cash's letter appears to relate to a meeting of the SNBTS and Haemophilia Directors which took place on 9 February 1987. According to the minutes of this meeting, Mr Duncan Macniven of the SHHD informed the meeting that:

The Department had consulted with Treasury, and ... a scheme similar to that already in force for the production of Anti-D would operate in the new factor VIII trials. Any claims would be considered by a 3 man panel and the ABPI guidelines<sup>295</sup> would apply.<sup>296</sup>

**24.149** However, it was also pointed out that, 'the new agreement would only apply to the initial trials of the new factor VIII' and not to its 'administration for therapeutic purposes'.<sup>297</sup> The minutes of the meeting also included a report from the SNBTS which noted that:

Plans are now well advanced for the introduction of a new factor VIII which is of higher purity and higher yielding. Further batches manufactured since January 1987 have been dry heated at 80°C for 72 hours to inactivate virus ... Dr Ludlam wished success to PFC's efforts to make a purer product still, and he and Dr Forbes agreed to accept the new product for trial.<sup>298</sup>

**24.150** According to Professor Ludlam's recollection, the minutes of this meeting (in particular the exclusion of compensation for therapeutic use) were not a correct record of the agreement which had been reached with the SHHD that cover would be granted from the first test infusion of a new Factor VIII product until the granting of a product licence.<sup>299</sup> In order to clarify this point, on 23 February 1987 Professor Ludlam wrote to Mr Murray querying what Mr Murray meant by 'clinical trial' and asking whether the SHHD interpreted this as meaning the period between the first test injection and the issuing of a full product licence.<sup>300</sup> On 26 February 1987 Dr Forrester minuted Mr Murray advising that:

I believe the answer to Dr Ludlam has to be that the Department is not yet in a position to follow the ABPI guidelines beyond the stage of where the injections begin to be given for treatment and not purely for reasons of testing. Furthermore, I understand that a full product licence may never be obtained from CSM, a body which is in any case not able to grant a licence at all. I told

<sup>299</sup> Appendix to Professor Ludlam's statement on Viral Inactivation, 1985–87 [PEN.017.1625] at 1637 and Professor Ludlam – Day 58, page 111

<sup>300</sup> Professor Ludlam's letter to Mr Murray of 23 February 1987 [SGH.003.1859]

Dr Ludlam informally recently of my doubts whether the full product licence procedure would ever go into action.

I understand today from Dr Perry that trials have already begun in any case.<sup>301</sup>

### Commencement of clinical trials

**24.151** Although Professor Ludlam still had queries about the precise scope of the compensation arrangements, clinical trials of Z8 were commenced in late February/early March 1987. These clinical trials, being Phase I trials, were to test the clotting and other properties of the product and could be completed in a few patients over a relatively short period. Phase II trials, which investigated whether the product was safe from the transmission of viruses, including NANB Hepatitis, would require to study use of the product by more patients over a far longer period.<sup>302</sup> It appears that it was initially intended that Phase I trials of Z8 would take place in Northern Ireland, Glasgow and Edinburgh. The Inquiry has, however, been unable to find any record of trials having taken place in Northern Ireland and there is no record of Z8 having been supplied to Northern Ireland for this purpose.<sup>303</sup> Although the evidence is not conclusive, it seems likely that clinical trials of Z8 took place in Glasgow in late February 1987. That is a reasonable inference from: (i) the Minutes of a Meeting of the Heads of Department/Section Managers of the PFC held on 17 February 1987 which refers to ‘the Glasgow Centre [having] received 75°C product for trial’;<sup>304</sup> (ii) a handwritten note dated 25 February 1987 from Dr Christopher Prowse of the Royal Infirmary of Edinburgh (RIE) to Dr Perry stating, as regards ‘the Z8-80 trial material’, that ‘I understand Glasgow have done 2 or 3 infusions successfully (from Dr Forbes). Your best contact there may be Dr Gordon Lowe’;<sup>305</sup> and (iii) a letter from Dr Perry to Professor Lowe of the Glasgow Royal Infirmary dated 30 March 1987 which appears to suggest that Professor Lowe had carried out infusions of Z8. The letter stated:

I understand that you have now infused this material into patients and that these infusions were uneventful.

I would be most grateful if you could provide me with a summary of this ‘trial’ (T½, recovery etc) so that I am in a position to release this new product for general use.<sup>306</sup>

**24.152** Dr Perry said that he was unable to find a reply to this request, the date(s) when the trial took place or the results of any trial.<sup>307</sup> The Inquiry has been unable to unearth any further details of the clinical trial of Z8 in Glasgow, including whether product for the trial was sent to Glasgow directly from the PFC or via Dr Boulton at the Edinburgh Regional Transfusion Centre.<sup>308</sup> Dr Boulton said that he was ‘unable to recall anything about the

<sup>301</sup> Dr Forrester’s minute to Mr Murray of 26 February 1987 [SGH.003.1853]

<sup>302</sup> For a discussion of the difference between Phase I and Phase II clinical trials see Professor Ludlam – Day 58, pages 118–121

<sup>303</sup> Dr Perry’s supplementary statement on Viral Inactivation, 1985–87 [PEN.017.2201] at 2202 and Dr Perry – Day 58, pages 78–82; and Appendix to Professor Ludlam’s statement on Viral Inactivation, 1985–87 [PEN.017.1625] at 1633

<sup>304</sup> Minutes of meeting of PFC Department and Section Managers, 17 February 1987 [SNB.010.3236] at 3237

<sup>305</sup> Dr Prowse’s memo to Dr Perry of 25 March 1987 [SNB.006.5619]

<sup>306</sup> Dr Perry’s letter to Dr Lowe of 30 March 1987 [PEN.017.2205]. See also Dr Perry’s supplementary statement on Viral Inactivation, 1985–87 [PEN.017.2201] at 2202

<sup>307</sup> Dr Perry’s supplementary statement on Viral Inactivation, 1985–87 [PEN.017.2201] at 2202. Dr Perry notes that given the date of his letter, ‘it seems likely ... that these trials took place after the trials which were eventually conducted by Professor Ludlam on 3<sup>rd</sup> March 1987’.

<sup>308</sup> Both Dr Cuthbertson and Dr Perry suggest that there is a possibility that Dr Boulton sent product directly to Dr Forbes. See Dr Cuthbertson – Day 57, page 67 and Dr Perry – Day 58, page 79

reported issue of any “Z8” from the Edinburgh and SE Scotland Transfusion Centre to any Scottish Haemophilia Centre’.<sup>309</sup>

**24.153** Clinical trials of Z8 took place in Edinburgh in February and March 1987. In his handwritten note dated 25 February 1987 to Dr Perry, Dr Prowse enclosed data on haemophilia patients infused with the ‘Z8-80 trial material’ and pointed out that Dr Susan Howe (RIE) could answer any queries on ‘clinical monitoring sheets’.<sup>310</sup> Dr Howe subsequently wrote to Dr Perry on 31 March 1987 enclosing the latest data on ‘haemophiliacs infused with Z8-80 trial material’ and indicated that ‘no further infusions are planned until Dr C Ludlam returns from holiday in three weeks time’, (ie at the end of April).<sup>311</sup>

### Z8 released for use

**24.154** By the end of March the issue of the precise scope of compensation for clinical trials of Z8 remained unresolved. On 12 March 1987 Professor Ludlam wrote to Dr John Forrester of the SHHD referring to the draft minutes of the SNBTS/Haemophilia Directors Meeting of 9 February 1987, reiterating his view that the compensation envisaged should apply to ‘all clinical trial infusions’ and asking Dr Forrester to clarify this matter ‘as it will be difficult to use the material therapeutically without this undertaking’.<sup>312</sup> On 25 March 1987 Dr Forrester circulated a minute within the SHHD, *Compensation Arrangements for Participants in Trials of PFC Products*.<sup>313</sup> The memorandum indicated that Dr Forrester had met Professor Ludlam on 24 March and explained that the SHHD’s position remained that participants who receive Factor VIII for ‘reasons of treatment as well as trial’ would not be covered by the compensation arrangements.

**24.155** At this point, the issue of the phasing out of the existing 68°C/24 hours product and the introduction of Z8 into the PFC’s batch dedication system came to the fore.<sup>314</sup> A report drawn up by Dr Perry for the SNBTS’s Supply and Demand meeting on 7 April 1987 noted that:

[T]here exists the need to phase out old product and phase in the new Z8. The following proposal is presented for consideration.

- (a) Batch dedication is maintained.
- (b) Residual NY and Z8 (75°/72 hrs) stocks are fed into the batch dedication system as normal.
- (c) An additional lane(s) is created at each RTC of Z8 (80°/72 hr) to make available material for special patient cohorts (eg virgins, elective surgery, mild haemophiliacs) prior to consumption of existing stocks of old material.

This will ensure equity of new product distribution whilst at the same time recognising the needs of special patient groups.<sup>315</sup>

<sup>309</sup> See [PEN.017.1825] for Dr Boulton’s response. Professor Cash was also unable to recall what occurred – see his supplementary statement [PEN.017.1874]

<sup>310</sup> Dr Prowse’s memo to Dr Perry of 25 March 1987 [SNB.006.5619]

<sup>311</sup> Dr Howe’s letter to Dr Perry of 31 March 1987 [SNB.006.5609].

<sup>312</sup> Professor Ludlam’s letter to Dr Forrester of 12 March 1987 [SGH.003.1849]

<sup>313</sup> Dr Forrester’s minute of 25 March 1987 [SGH.003.1847]

<sup>314</sup> The batch dedication system was introduced with a view to increasing patient safety. It enabled patients to be treated with product from the same manufacturing batch, thereby restricting the number of batches (and hence donors) a patient was exposed to. Professor Cash – Day 57, pages 120–123.

<sup>315</sup> Dr Perry’s report of March 1987 [SNB.004.0529]

**24.156** In other words, it was intended that there would be a phased introduction of Z8. Existing stocks of the 68°C/24 hours product (NY) would be exhausted under the PFC's standard batch dedication system before a switch to Z8 was made. It was also recognised, however, that certain patients (eg previously untreated patients) should receive Z8 at an earlier date.<sup>316</sup> Dr Perry's report noted that 'at present rates of demand it is estimated that Z8 will become available for all patients by July 1987'.<sup>317</sup>

**24.157** Around this time (April 1987), Phase I trials of Z8 had been successful and it was concluded that the product could be released for clinical use. In particular, on 10 April 1987 Professor Cash wrote to Dr Perry explaining that 'Dr Cuthbertson and I have reviewed the raw data from the Edinburgh patients and I am satisfied that PFC may now move to issue Z8 for routine clinical use'.<sup>318</sup> During the Inquiry hearings Dr Perry indicated that it was likely that Dr Boulton would have presented a report to Professor Cash on the studies and that Professor Cash, in his role as SNBTS National Medical Advisor, would have considered this report and authorised the release of Z8.<sup>319</sup> Professor Cash's letter was followed on 15 April 1987 by the release to Glasgow of 830 units of the 75°C/72 hours Z8 product for clinical use.<sup>320</sup> On 22 May 1987, 368 units of the 80°C/72 hours Z8 product were released to Glasgow.<sup>321</sup> The last issue of the existing 68°C/24 hours (NY) product was made on 13 May 1987.<sup>322</sup>

**24.158** The gradual introduction of Z8, in terms of the batch dedication scheme, followed in the period May–July 1987.

**24.159** Although reference was made to Z8 being released for 'routine' use, given that no product licence or clinical trial certificate had been issued, it appears that Z8 was prescribed to patients on the basis of the 'named patient' exemption in the Medicines Act 1968 (which applied to medicinal products 'specially prepared' for a doctor 'for administration to a particular patient').<sup>323</sup>

### Compensation arrangements extended

**24.160** The issue of compensation for trials of Z8 continued to be discussed. The minutes of a meeting of the SNBTS Directors on 10 June 1987 record that 'in Mr Murray's absence Dr Forrester explained that the SHHD had extended the Treasury Compensation Scheme to Z8' and that 'Miss Corrie and the CSA Secretary were working together on draft proposals for revision of the current compensation scheme'.<sup>324</sup> The minutes also noted that 'Dr Forrester recommended that the agency should get the ABPI guidelines extended to cover all SNBTS products for all trials involving volunteers of any product given for non-

<sup>316</sup> For more information on the phased introduction of Z8 see: Dr Perry's statement on Viral Inactivation, 1985–1987 [PEN.017.1219] at 1222–23; Dr Perry – Day 58, pages 94–95; and Professor Ludlam – Day 58, pages 128–129

<sup>317</sup> Dr Perry's report of March 1987 [SNB.004.0529]. Dr Perry clarified in his written statement that the July 1987 date was his best estimate at the time of when all product at issue would have been Z8 (ie when stocks of the existing 68°C/24 hours product would have been exhausted). See Dr Perry, Day 58, pages 94–95.

<sup>318</sup> Professor Cash's letter to Dr Perry of 10 April 1987 [PEN.017.1267]. (Dr Cash became a Professor in April 1987).

<sup>323</sup> Professor Ludlam – Day 58, pages 122–124. See also the Medicines Act 1968, sections 7, 9(1) and 31. In addition, there was an ongoing debate at the time as to whether the legal doctrine of Crown Immunity exempted the NHS and the PFC from the legal requirement to obtain manufacturers' and product licences in respect of products manufactured by them.

<sup>324</sup> Minutes of SNBTS Directors' meeting, 10 June 1987 [SGF.001.0127] at 0133

therapeutic reasons'. On 10 June 1987 Mr Murray, SHHD, wrote a letter to Mr Donald (the General Manager of the CSA) indicating that the Treasury had granted approval for a compensation scheme for Factor VIII trials in line with ABPI guidelines. The letter stated:

The Department has sought Treasury approval to appropriate arrangements for compensation in the event of injury during clinical trials of Factor VIII. We sought cover for those haemophilia patients participating in clinical trials to ascertain the quality and efficacy of new batches of Factor VIII which have been subjected to the improved heat-treatment process.

Treasury approval has now been received to a compensation scheme adhering to the guidelines recommended by the Association of the British Pharmaceutical Industries.<sup>325</sup>

**24.161** Professor Ludlam remained dissatisfied, however, that the compensation scheme was limited to use of the product during clinical trials and did not extend to its use in the period after trials had been concluded and before a product licence was obtained. On 11 June 1987 he wrote to Dr Forrester reiterating that he did not view the draft minutes of the meeting of Haemophilia/SNBTS Directors on 9 February 1987 as a correct record of the meeting and that he was of the view that Mr Macniven had given an undertaking that all infusions of Factor VIII would be covered by the compensation scheme.<sup>326</sup> Professor Ludlam also wrote to Dr Boulton on 11 June indicating that he had been led to believe that the issue of Z8 to patients had begun and expressed concern that that had taken place without 'a Product Licence from the CSM' or a 'Clinical Trials Exemption Certificate'.<sup>327</sup> Professor Ludlam's letter indicated that it was unclear 'who is responsible for any adverse side effects' and emphasised that in his view the minutes of the meeting of Haemophilia/SNBTS Directors on 9 February 1987 were incorrect and that the SHHD compensation arrangements should apply to all test infusions to assess clinical efficacy (ie Phase II trials) and not just half-life tests (ie Phase I trials).<sup>328</sup> The letter described the decision to introduce Z8 as a 'fait accompli' and Professor Ludlam indicated that he was forced 'either to accept the situation ... or to go over to the purchase of commercial factor VIII'.<sup>329</sup>

**24.162** In a letter of 25 June 1987 Professor Cash advised Professor Ludlam that he was in no doubt that the minutes of the meeting of Haemophilia/SNBTS Directors on 9 February 1987 were correct and that the SHHD's compensation scheme only included cover for half-life studies.<sup>330</sup> He also indicated that the reason for introducing Z8 was due to the shortage of the PFC's current 68°C/24 hours product, which was the result of 'the long delay in establishing the t/2 studies' and that Professor Ludlam's mention of giving patients the option of using commercial products was 'opening a Pandora's box'.<sup>331</sup> The letter closed by stating that, 'we're taking every possible step to expedite the licensing of Z8'.

**24.163** Professor Ludlam responded to Professor Cash's letter on 30 June 1987, outlining in more depth (albeit in a conciliatory manner) his concerns as regards compensation and the introduction of Z8 and stating that, 'as Z8 is under clinical trial I must reserve the right to use another product if the patient refuses to accept the trial material, but I need not

make this explicit'.<sup>332</sup> Professor Cash responded to this letter on 13 July 1987 suggesting that he and Professor Ludlam meet to discuss the various issues.<sup>333</sup>

**24.164** In the meantime, on 6 July 1987 Professor Ludlam wrote to the Medical Defence Union<sup>334</sup> and a contact (Dr Leonard) at the relevant Ethics Committee<sup>335</sup> outlining his (Professor Ludlam's) understanding that (i) the current issue of Z8 could be considered as a Phase II clinical trial to assess clinical efficacy; (ii) there was no clinical trial certificate; and (iii) that current SHHD compensation policy would not cover patients who experienced a severe reaction. Dr Leonard responded on 8 July 1986 indicating that Professor Ludlam should convey to the SHHD his misgivings about the use of Z8 when it 'has not received the appropriate ABPI cover'.<sup>336</sup>

**24.165** Shortly thereafter, the compensation arrangements were extended, as Professor Ludlam had wished, to cover the continued prescription of Z8 beyond the Phase I trial. On 8 July 1987, Professor Cash wrote to Mr Macniven noting that 'there is now a need for ... the creation of a new concept ... – compensation for products undergoing trials when the product is being given for therapeutic purposes (Type II)'.<sup>337</sup> On 9 November 1987, following further correspondence between the various parties,<sup>338</sup> Mr Macniven responded to Professor Cash explaining that the SHHD had reassessed its position and had concluded that the existing compensation arrangement should now also apply to therapeutic trials.<sup>339</sup> Professor Cash passed on Mr Macniven's news to Professor Ludlam who replied on 19 November indicating that he was 'delighted' that the SHHD had agreed to extend compensation to cover therapeutic trials of Factor VIII.<sup>340</sup> Although further discussion followed regarding the technicalities of the compensation scheme,<sup>341</sup> by November 1987 the underlying issue of compensation for the continued use of Z8 (and, indeed, other products manufactured by SNBTS) had finally been resolved.

### 1988 to 1991

#### Evidence of viral inactivation in Factor VIII concentrates heated to 80°C for 72 hours

**24.166** Although Z8, heated to 80°C for 72 hours, had been introduced from the middle of 1987 there was still work to be done in order to confirm the effectiveness of viral inactivation.

**24.167** A formal Phase II clinical trial for Z8 in 'virgin' patients was set up in 1988.<sup>342</sup> Professor Ludlam explained that the trial was:

[A] national study to monitor patients who received Z8 for the first time under the protocol laid down by the ISTH,<sup>343</sup> which was a very rigorous protocol – fortnightly blood samples for, I think, the first 16 weeks and then monthly for two months, looking at ALT levels.<sup>344</sup>

<sup>343</sup> The International Society on Thrombosis and Haemostasis, an international blood organisation

<sup>344</sup> Professor Ludlam – Day 58, pages 130–131

**24.168** In 1989 Mrs Winkelman and others published on the method of manufacture of the BPL's 8Y Factor VIII (dry-heated at 80°C for 72 hours).<sup>345</sup> The key step in the new manufacturing process was said to be the use of heparin at temperatures above ambient to precipitate fibrinogen and fibronectin. Good results were reported.<sup>346</sup> In 1989 a paper by Pasi and others was published reporting that the BPL Factor VIII product 8Y appeared to have prevented transmission of HCV and HIV.<sup>347</sup>

**24.169** By November 1989 when Professor Ludlam provided his expert opinion to support the SNBTS's application for a product licence variation for Z8 he was able to report that:

Factor VIII Z8 has been the concentrate treatment of first choice for my patients since its introduction into routine use in 1987. This is consistent with the view of the UK Haemophilia Reference Centre Directors report ... which recognises FVIII products which have been dry heat-treated at 80°C for 72 hours as being amongst the safest available products with regards to the risk of virus transmission.<sup>348</sup>

**24.170** At this stage, publication was often some years after work was done. The paper by Mrs Winkelman and others referred to at paragraph 24.168 above, published in 1989, reflected work done three to four years earlier. Similarly, commercial products approved and marketed around 1989 were often the result of research and Phase I and II trials carried out several years earlier.

**24.171** The results of the Scottish and Northern Irish Phase II study were not published until 1993. The paper contained the following summary:

To assess the viral safety of the Scottish National Blood Transfusion Service (SNBTS) intermediate purity Factor VIII and IX concentrates, the liver function and viral status were assessed prospectively in 13 recipients. None developed hepatitis or seroconverted to HIV or HCV. This study provides additional evidence for the efficacy of dry heat treatment at 80°C for 72 h in preventing virus transmission by coagulation factor concentrates.<sup>349</sup>

### Regulatory framework for viral safety

**24.172** In the UK, the regulatory framework for ensuring viral safety was about to change. The first meeting of the Advisory Committee on the Virological Safety of Blood (the ACVSB) was held on 4 April 1989.<sup>350</sup> The ACVSB was expected to have a role in relation to regulation: the EC Directives on blood products could have a major impact on the UK. Products that had until this time been made under Crown privilege would have to be licensed. Blood would have to be harvested from donors selected according to the Directives and certain tests for virological conditions might be mandatory. It would also have regard to NANB Hepatitis, in respect of which it was recorded that the issue of

<sup>350</sup> Minutes of first meeting of Advisory Committee on the Virological Safety of Blood, 4 April 1989 [SNF.001.1219]; Membership of ACVSB [SNB.001.9364]; Terms of Reference [SNB.001.9366]; Overview of issues for ACVSB [SNB.001.9368]

surrogate or direct testing for NANB Hepatitis was of some urgency. The activities of the ACVSB and the Advisory Committee on Transfusion-Transmitted Diseases (ACTTD) are examined elsewhere in relation to a number of topics of interest to the Inquiry and, in particular, surrogate testing and later HCV screening.

**24.173** At the second meeting of the ACVSB on 22 May 1989 the UKBTS/NIBSC Guidelines (Draft March 1989), Part 5, dealt with viral inactivation, and set out a specification for the validation of virus inactivation procedures to be used during the manufacture of clotting factor concentrates.<sup>351</sup>

#### Development of a higher purity product (S8) and clinicians' concerns about Z8

**24.174** Through this time SNBTS continued with research and development work for a high purity product, now designated S8. The 'S8 Group' met on 28 February 1989.<sup>352</sup> The date of the first full clinical trial production run was confirmed as 3 April 1989. However, a number of research and development issues remained to be resolved. A draft specification for the new product was prepared<sup>353</sup> and circulated with the notes of the S8 Group meeting held on 10 May 1989.<sup>354</sup> A forward programme was agreed.

**24.175** The report of the first meeting of the Scotland and Northern Ireland Factor VIII working party, dated April 1989, commented on the PFC's Z8 product.<sup>355</sup> It was thought that Z8 was not an optimal product. The working party strongly supported a project for a new higher purity concentrate (now designated S8), noting that development had progressed more slowly than originally anticipated. It was anticipated that the first infusions would occur in June and a formal Phase I study (of percentage recovery and half life) would take place at the premises of Drug Development (Scotland) Ltd in September. Thereafter a Phase II study would follow to demonstrate clinical efficiency. The report on viral safety of Z8 noted that there was no evidence to suggest the product would transmit HIV or NANB Hepatitis, and that there was substantial evidence to demonstrate HIV safety. There were said to be very few data positively to demonstrate NANB Hepatitis safety. However, the opinion of the group was that at that stage only heat treatment was preferable to a solvent detergent technique.

**24.176** Professor Ludlam presented the first report of the working party to a meeting of the SNBTS and Haemophilia Directors on 21 July 1989.<sup>356</sup> The new product S8 was discussed: the Haemophilia Directors expressed the hope that this product, which had the same purity as commercial products, would be available soon. Z8 had a low purity. Professor Ludlam said that there was an international movement towards high and very high purity products 'even though evidence of their value was lacking',<sup>357</sup> and that Directors were coming under pressure to use them. It was pointed out that purity did not equate with safety, and was associated with lower yield.

**24.177** The S8 group met on 10 November 1989.<sup>358</sup> It identified priority areas for action including additional plant, assay development, stabilisers and other specific matters related to the manufacturing process. Various options for development of the high purity

<sup>356</sup> Note of SNBTS Directors and Haemophilia Directors meeting, 21 July 1989 [SGH.001.7491]

<sup>357</sup> Ibid [SGH.001.7491] at 7493

<sup>358</sup> Minutes of meeting held on 10 November 1989 [SNB.007.6933]

product were discussed, and in particular terminal heating (including both dry and wet heat and possibly solvent-detergent) as virucidal steps. It was agreed that there would be empirical and theoretical studies of variables. Existing and novel stabilisers were to be studied. Assays for detergents and solvents were to be set up. Work was to be done on viral inactivation of Hepatitis B (especially by wet heat treatment). A period of three years to clinical trials was thought to be a reasonable estimate of the time required. In relation to Hepatitis B, it was noted that a major area requiring discussion was how toxicology and safety should be tackled.

**24.178** On 30 November 1989, there was a 'Z8 trouble shooting' meeting.<sup>359</sup> Analysis had demonstrated increasing fibrinogen content in process cryoprecipitate resulting from coolant problems. The increase made the overall Z8 process less efficient, and led to a decline in solubility. The emerging complaint of the Haemophilia Directors about the usefulness of the product (related to its solubility) appeared to have been substantiated. Improvements were scheduled for research and development.

**24.179** In 1990 the approach to manufacture changed, with development involving collaboration with the Centre Régional de Transfusion Sanguine (CRTS), Lille, in the production of purer products. Dr Prowse of the SNBTS South East Regional Centre and Department of Transfusion Medicine reported to Professor Cash, Dr Foster and Dr Pepper on the results of heat treatment at 80°C for 72 hours of Lille concentrates, including High Purity FVIII. The appearance of the FVIII product following treatment was 'clear'. Dr Prowse concluded that it appeared that terminal heat treatment could be a valid option for 'high purity' products.<sup>360</sup>

**24.180** Dr Prowse prepared a development proposal for a virally inactivated FVIII concentrate in a paper for the SNBTS Product Development Group in April. The PFC's recurrent problems, in which he included the critical limits in terms of freeze drying for success in severe heat treatment, and advice from Dr Smith on the difficulty in achieving severe heat treatment of products under 10mg/ml, led him to conclude that the SNBTS would need to adopt established solvent detergent technology in due course. He commented:

However, recent in-house data on heat treatment of the Lille product ... suggests it may be possible to retain in excess of 70% VIII activity at a specific activity of 100u/mg. Thus we should not abandon terminal treatment, but should continue to work on this as a 'belt and braces' approach.<sup>361</sup>

**24.181** Among other proposals, and having regard to time constraints, he advocated sub-licensing an established technology such as that used by the CRTS Lille. He also proposed a collaborative effort with England and Wales.

**24.182** The need for a high purity product had been discussed by Professor Cash in a memorandum dated 22 May 1990.<sup>362</sup> In relation to viral inactivation, he thought that terminal dry heating should not lightly be abandoned but, because there was an open invitation to acquire the CRTS Lille technology, solvent detergent had to be considered seriously. By now, the vast majority of the world's fractionators had taken that route. He proposed that the PFC 'bite the bullet' and opt for the total Lille package.

---

<sup>359</sup> Notes of Z8 trouble shooting meeting, 30 November 1989 [SNB.007.6957]

<sup>360</sup> Dr Prowse's memorandum to Professor Cash and others of 2 February 1990 [SNB.007.7024]

<sup>361</sup> *Factor VIII Development Proposal*, Dr Prowse, April 1990 [SNB.007.7074]

<sup>362</sup> Professor Cash's memorandum on Factor VIII concentrates into the 1990s, dated 22 May 1990 [SNB.005.3141]

**24.183** Dr Foster and Dr McIntosh visited Lille on 9–11 July 1990 and prepared a report.<sup>363</sup> They had mixed impressions of the Lille operation. Some aspects of the plant impressed, but the general conclusion was that practice was not up to US or UK standards. The reporters thought that collaboration was required on a range of technical matters, and recommended a review of the SNBTS's strategy for development of a high purity Factor VIII.

**24.184** On 13 July 1990, it was reported that Dr Prowse was making progress in establishing a joint venture with the NIBSC on the immunosuppressive properties of Factor VIII concentrates.<sup>364</sup> This was of potential importance because there had been suggestions that, because of their lack of purity, Z8 and S8 might contain proteins which might lead to impaired immune response if administered chronically.

**24.185** Discussions with Lille continued, and regulatory requirements in France were progressed in October 1990.<sup>365</sup> On 30 October 1990, the SNBTS sent details of the PFC's methods for preparation of Factor VIII (S8) to Lille.<sup>366</sup> The CRTS had prepared documentation for licence purposes and arrangements were made for the SNBTS to have access to that documentation if it was decided to proceed with the Lille process.<sup>367</sup> This was the beginning of a new chapter in factor concentrates research and development.

**24.186** There was continuing contact with the New York Blood Centre relating to licensing of solvent/detergent technology. This was a necessary treatment step in the manufacture of the Lille product. Discussions with the New York Centre established the licensing arrangements and fees required for access to its solvent/detergent technology on 21 January 1991.<sup>368</sup>

**24.187** On 3 May 1991 a technology exchange agreement was signed between the French and the Scottish blood transfusion services to enable the SNBTS to produce a high purity Factor VIII using CRTS technology.<sup>369</sup>

**24.188** There continued to be wide-ranging research and development in Scottish laboratories in 1991 and beyond. Dr Foster wrote an interesting and typically perceptive article on the history of the Protein Fractionation Centre, tracing its final stages in particular, in 2008.<sup>370</sup> Chapter 11 of the Preliminary Report gave an account of some of that work.

**24.189** However, the developments bearing on the issues raised by the Terms of Reference had all taken place by the end of 1990 or early 1991. Transmission of infection with HIV and HCV by SNBTS products, now subject to effective terminal heat treatment, was no longer an issue and it is not appropriate to discuss at length the evolving history of the final years of PFC research, development and production of factor concentrates.

## Discussion

### *Should Z8 have been developed earlier?*

**21.190** As discussed above, in England 8Y (dry heat-treated at 80°C for 72 hours) was issued for general release to Regional Transfusion Centres in September 1985. The equivalent PFC product, Z8, was available for general use from April 1987. The question arises whether the PFC ought to have developed a Factor VIII product that did not transmit NANB Hepatitis/HCV earlier. That question involves a consideration of:

- (a) The initial priority given by the PFC to developing a high purity Factor VIII concentrate (NYU) that could be pasteurised.
- (b) Whether PFC ought to have taken the decision at an earlier stage to prioritise the development of an intermediate Factor VIII product that could be severely dry-heated.
- (c) Whether the product that was developed (Z8) ought to have been available for clinical trials before December 1986.
- (d) Whether there was a failure to address timeously Professor Ludlam's concerns in respect of compensation for patients who suffered harm in clinical trials and, if so, whether any such failure resulted in a delay in (i) the commencement of clinical trials and (ii) the availability of Z8 for use by patients.

Each of these issues will be considered in turn.

### **(a) The initial priority given by the PFC to developing a high purity Factor VIII (NYU) and pasteurisation**

**24.191** The development of a high purity Factor VIII product that could be virally inactivated by pasteurisation had priority in the PFC's research and development programme in 1984 and 1985. At that time, the PFC remained alert to the possible introduction of other viral inactivation procedures including, in particular, dry heating. There was ample evidence before the Inquiry that a focus on the development of a high purity product at that time was reasonable given the demands of the Haemophilia Directors for a higher purity product and the initially promising results of the PFC's collaboration with Professor Johnson aimed at producing an appropriate product. Pasteurisation, rather than dry heating, was also supported by evidence available at the time that wet heating of factor concentrates might be effective in preventing transmission of NANB Hepatitis (specifically the Behringwerke work discussed elsewhere in this Report); and that dry heating (at least at 68°C, the temperature in common use at the time) was not effective in preventing the transmission of NANB Hepatitis. There was also evidence that, in the case of some products, dry heating was not effective in preventing the transmission of HIV (paragraphs 24.83 and 24.120).

**24.192** In his evidence Dr Foster explained that during 1985 his judgement was that 'in terms of the data that were available, the better data came from the pasteurisation process in terms of safety to patients',<sup>371</sup> whilst adding that:

[W]e were positioning ourselves to change if we got new information that showed that perhaps dry heat treatment, for very severe conditions, was going to be a good option. And that, if we had to ... heat at 80 or go beyond 80,

---

<sup>371</sup> Dr Foster – Day 56, pages 85–86

the higher purity product should be capable of doing that because it was much more highly purified than 8Y.<sup>372</sup>

**24.193** According to Dr Foster, the understanding, common to English and Scottish scientists, that the PFL/BPL's success in heating 8Y to 80°C was based on its higher purity confirmed that the PFC was following the correct route in focussing on a high purity product. If pasteurisation did not prove effective then severe dry heating might provide an alternative method of viral inactivation.<sup>373</sup>

**24.194** Dr Perry stated:

I think our belief ... was that pasteurisation remained the best option. And colleagues from the BPL to an extent actually agreed with that because there was some experience from the Behringwerke product that pasteurisation was likely to deliver a safe product. So we still felt that was the best option.<sup>374</sup>

**24.195** Other witnesses to the Inquiry shared this view. In particular, Professor Van Aken, who provided expert assistance to the Inquiry, was of the view that at the start of 1985 it was reasonable — given the needs of the market — for the PFC to dry heat-treat their existing intermediate purity NY product (at 68°C for 24 hours) to deal with the immediate threat of HIV while having the long-term aim of applying pasteurisation to a high purity product.<sup>375</sup>

**24.196** Dr Smith of the PFL/BPL gave evidence stating that 'my correspondence etc., shows that, even for someone identified closely with 8Y, pasteurisation seemed likelier than dry heating to defeat NANBH, at least through 1986 ...'.<sup>376</sup> He was of the view, during the whole of 1985, that pasteurisation would have been 'the better horse to back' if the aim was to inactivate NANB Hepatitis.<sup>377</sup>

**24.197** The evidence on the prioritisation of pasteurisation is accepted as reliable, and persuasive of the appropriateness of the course adopted by the SNBTS. There is independent objective support for the pasteurisation option in the evidence, noted in paragraph 21.121, that from about 1986 some commercial pharmaceutical companies were beginning to market pasteurised products. The research and development priorities of the SNBTS were consistent with wider industry practice in those cases, in which the pasteurisation process must have been developed over the material period.

**(b) Whether PFC ought to have decided earlier to develop an intermediate Factor VIII product that could be severely dry-heated**

**24.198** The initial understanding that the PFL/BPL's success in developing 8Y in England in 1984 and 1985 depended on the high purity of the product (which distinguished it from the PFC's existing intermediate purity NY Factor VIII product) changed after Dr McIntosh's discovery in October 1985 that the freeze-drying process appeared to be more important than purity in the product's ability to withstand severe dry heating. Dr Foster wrote at the time that the importance of the freeze-drying step to the product's subsequent ability to withstand heating was 'not entirely unexpected', given the interaction of all of the steps

<sup>372</sup> Dr Foster – Day 56, page 86

<sup>373</sup> Dr Foster – Day 56, page 85

<sup>375</sup> Professor Van Aken – Day 62, pages 31–32

<sup>376</sup> Dr Smith's statement on Viral Inactivation, 1985–87 [PEN.017.1130] at 1140

<sup>377</sup> Dr Smith – Day 60, page 92

in the production process. However, this had the quality of hindsight (paragraph 24.76), inevitable in a review of what had been discovered. There was no evidence available to the Inquiry to support a view that, prior to Dr McIntosh's discovery, the PFC ought to have considered that severe dry heat treatment of an intermediate purity Factor VIII concentrate was a realistic possibility, or that the priority given to developing a high purity Factor VIII product should be reassessed. The available evidence was to the contrary effect.

**24.199** Dr Perry explained to the Inquiry that the key information which triggered the change of direction at the PFC was, 'the experiments conducted by Dr McIntosh and the realisation that ... you could heat a relatively low purity product at 80 degrees for 72 hours'. He said that information was not available to the PFC before Dr McIntosh's discovery. Their belief prior to that was that 'pasteurisation remained the best option'.<sup>378</sup>

**24.200** In his written evidence Professor Van Aken stated:

In retrospect it may be asked if PFC should have changed its policy at an earlier stage, i.e. before December 1985. In my opinion, which is shared by Dr Smith, PFC had good arguments to pursue the wet heating of factor VIII concentrate as it was doing. Before December 1985 it was uncertain if the BPL product would be safer than the SNBTS/PFC product.<sup>379</sup>

**24.201** Dr Smith's evidence, as noted above, to the effect that even for someone identified closely with 8Y, 'pasteurisation seemed likelier than dry heating to defeat NANBH, at least through 1986'.<sup>380</sup> and that, during the whole of 1985, his view was that pasteurisation would have been 'the better horse to back' if the aim was to inactivate NANB Hepatitis, is material.<sup>381</sup>

**24.202** The novelty of a discovery is not necessarily undermined by analysis after the event that suggests that the discovery could have been anticipated. The evidence that Dr McIntosh's findings, which were at the time unexpected, changed the course of events is accepted. So far as the evidence available to the Inquiry shows, until October 1985 there was no experimental or other scientific data that should have prompted the SNBTS and the PFC to change direction in their dry heating research programme.

**(c) Whether the product that was developed (Z8) ought to have been available for clinical trials before December 1986**

**24.203** In developing the Z8 process, SNBTS scientists were able to draw on elements of the NYU process developed in conjunction with Professor Johnson of New York.<sup>382</sup> Witnesses from the SNBTS and the PFC indicated that certain elements from that programme played a key role in the subsequent development of the Z8 process. Dr McIntosh, for example, was of the opinion that:

[T]he experience and expertise gained during the development of a number of the processing steps in the NYU project (e.g. cryo-precipitate processing, formulation, freeze-drying) were directly transferrable to the Z8 process.<sup>383</sup>

<sup>383</sup> Dr McIntosh's statement on Viral Inactivation, 1985–87 [PEN.017.1234] at 1238

Nevertheless, the evidence suggested that considerable research and development work was required.

**24.204** Although Dr McIntosh discovered in October 1985 that vials of the PFC intermediate purity product withstood dry heat treatment at 80°C, various witnesses commented that this was a very preliminary finding in a laboratory setting and that a significant amount of further research and technological development was needed before a product so heated could be manufactured on a large scale.<sup>384</sup> Dr Foster, for example, explained that the production of Z8 ‘required a new manufacturing process to be established from the recovery of cryoprecipitate onwards’.<sup>385</sup>

**24.205** Dr Cuthbertson set out in detail the steps required to introduce a new product:

The development of a new product is a very detailed process and a large number of steps must be carried out in a meticulous manner in order to ensure that the final product meets the basic pharmaceutical requirements of safety, quality and efficacy. Nowadays it is believed that the development of a new process from development, through clinical trialling to final licensing and routine issue will take of the order of 5 years. In those days, the regulatory requirements were not so rigorous, but even so, implementation of a new process required significant periods of time to include the following steps

- Development of process at R+D scale
- Understanding of safety issues (including virus inactivation studies)
- Clinical evaluation, to include
  - Freedom from adverse reactions, including use in repeat infusions
  - Acceptable recovery of clotting factor in circulating plasma
  - Development of product at pilot scale
  - Acceptable recovery in the circulation and in vivo half life
- Process scale up
- Development of effective quality control (test) and quality assurance procedures
- Demonstration that process can be adopted routinely with acceptable reproducibility (there is no point in producing a product with poor yield or poor reproducibility)
- Production of enough material at manufacturing scale, whilst ensuring that existing product is still available.<sup>386</sup>

**24.206** Professor Van Aken had a similar view of the need for various steps to be taken to progress from laboratory scale to pilot scale and subsequently full production scale, concluding that, ‘in my opinion it is quite an achievement to successfully complete all this within one year (in fact between June and December 1986)’.<sup>387</sup>

<sup>385</sup> Dr Foster’s statement on Heat Treatment, 1985–1987 [PEN.017.1556] at 1563

<sup>386</sup> Dr Cuthbertson’s statement on Viral Inactivation, 1985–1987 [PEN.017.1200] at 1202. For the timing of certain of these phases see Dr Foster’s statement on Heat Treatment, 1985–1987 [PEN.017.1556] at 1561

<sup>387</sup> Professor Van Aken’s statement on viral inactivation, 1985–1987 [PEN.017.1597] at 1602

**24.207** In addition, and perhaps unsurprisingly, when developing and scaling up a new product and manufacturing process, unexpected technical problems arose that required to be overcome. Dr Foster<sup>388</sup> and Dr McIntosh<sup>389</sup> explained that a number of unexpected technical/management issues occurred during the development and production of Z8 which delayed its introduction. In addition to the ‘eleventh hour’ freeze-drying problems in August 1986 discussed above, there were also problems sourcing suitable ultra-filtration pumps which would operate at a larger scale without damaging the Factor VIII<sup>390</sup> and there was a need to revise the Z8 production process so that it could be performed without having to alter existing PFC staffing arrangements, and hence PFC employees’ terms and conditions of employment.

**24.208** The evidence that the time taken between a decision in late 1985/early 1986 to prioritise the development of Z8 and the development, production and availability of that product for clinical trials by the end of 1986 was not unreasonable is accepted. The evidence went further, to the effect that the timescale achieved was remarkably quick, in particular when judged against modern practices and timescales for the development of new pharmaceutical products. That evidence is also accepted.

**(d) Whether there was a failure to address timeously Professor Ludlam’s concerns in respect of compensation for patients who suffered harm in clinical trials and, if so, whether any such failure resulted in a delay in (i) the commencement of clinical trials and (ii) the availability of Z8 for use by patients**

**24.209** The question of compensation for patients who suffered an adverse reaction to clinical trials of PFC products was first raised by Professor Ludlam with the SHHD in late 1983 and, despite his best efforts, remained unresolved by late 1986, when Z8 became available for clinical trial. In particular, Professor Ludlam raised the issue of compensation at a meeting of the Haemophilia and Blood Transfusion Working Group on 14 November 1983 (at which Dr Bell of the SHHD was present);<sup>391</sup> at the meetings of the SNBTS and Haemophilia Directors on 2 February 1984 and 7 March 1985 (at which Drs Bell and McIntyre were present);<sup>392</sup> in his letter dated 19 March 1985 to Dr Boulton;<sup>393</sup> and in his letter dated 4 April 1985 to Professor Cash.<sup>394</sup>

**24.210** When Z8 became available for clinical trials in December 1986, Professor Ludlam, with the support of the other Haemophilia Directors, refused to undertake trials of the product unless satisfactory compensation arrangements were in place for patients suffering damage as a consequence of infusion of the new product. In oral evidence to the Inquiry Professor Ludlam explained:

I had one of two options. One was to roll over and say, ‘There shouldn’t be compensation arrangements,’ and get on and test the product or I should say, ‘I won’t test it’. I’m there as a patient’s advocate in this instance and it seemed to me that if I didn’t draw a line at this point, there might never be

<sup>388</sup> Dr Foster’s statement on Heat Treatment, 1985–1987 [PEN.017.1556] at 1562; and SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1351–56

At the meeting on 7 March 1985 Professor Cash explained the difficulties the SNBTS had in attempting to resolve the problems through the CSA. Professor Ludlam was noted as requesting that some action be taken ‘urgently’.

<sup>393</sup> Professor Ludlam’s letter to Dr Boulton of 19 March 1985 [SNB.005.7320]

<sup>394</sup> Professor Ludlam’s letter to Professor Cash of 4 April 1985 [SNB.005.7332]

arrangements and there might be some terrible consequence of one of these test infusions and then one would be dependent on the CSA's goodwill. I felt it only fair to the patients that there was something a bit more explicitly available than just the hope that there would be goodwill.<sup>395</sup>

**24.211** SHHD witnesses gave evidence to the Inquiry to the effect that the reason why Professor Ludlam's concerns over compensation for clinical trials had not been resolved by late 1986 was, partly, because the SHHD considered that the issue was one on which the CSA should take the lead and, partly, because Professor Ludlam's concerns over compensation for patients became caught up with the wider, more complex, issue of compensation for trials involving healthy volunteers, specifically trials and immunisation procedures involving SNBTS staff members and blood donors.<sup>396</sup> Reliance on a CSA lead in 1986 could only have related to the consequential financial aspects of a compensation scheme. The policy question whether a scheme was appropriate was a matter for SHHD and ministers.

**24.212** Mr Murray, SHHD, agreed that, in retrospect, the time taken to deal with the question of compensation was unsatisfactory.<sup>397</sup> When asked to explain in more depth why the issue took so long to resolve, Mr Murray explained that:

[I]n reviewing the papers, not from my memory but from my reading of the documentation, there would appear to be a fragmentation of attention. And we have – we have the meetings of the regional directors and those responsible for haemophilia, we have the BTS subcommittee, we have the CSA central administration, we have Scottish Home and Health Department medical officers and then we have the administrative side of the department. The answer to your question, I think, lies in those structures.<sup>398</sup>

**24.213** In his evidence to the Inquiry, Mr Macniven (who was in post from May 1986) indicated that a key issue was lack of focus as regards the scope of the proposed compensation scheme. He stated:

[T]he way to have resolved this much more quickly was to stick to what Dr Ludlam was asking, stick to the narrow question, which, as we demonstrated in early 1987, was relatively simply for Treasury to answer .... The delay was engendered for a number of reasons but because people were uncertain about what breadth of compensation scheme we were talking about: Were we talking about a scheme that involved all clinical trials of all possible future SNBTS products? That's a larger blank cheque for Treasury to write out, or to approve us writing out, than the narrow scheme, which they were used to, as we saw earlier, in other contexts.<sup>399</sup>

**24.214** There is support in the evidence for the view that the SHHD should have taken the lead in resolving Professor Ludlam's concerns in respect of compensation, and that that could have been done relatively easily by disentangling the issue raised by Professor Ludlam from the issue of compensation of healthy volunteers and donors who were trialling different products. The introduction of any compensation scheme of wide application

---

<sup>395</sup> Professor Ludlam – Day 58, page 141–2. See also Day 58, page 107.

<sup>396</sup> Dr McClelland's paper dated 20 August 1984, *Clinical Trials – Compensation for Medicine Induced Injury* [SNF.001.3013]

<sup>397</sup> Mr Murray – Day 61, page 142

<sup>398</sup> Mr Murray – Day 61, page 143

<sup>399</sup> Mr Macniven – Day 61, page 163

raised issues of health policy and had financial implications that would, inevitably, have required the consent of the Treasury. When the SHHD finally did take responsibility for resolving Professor Ludlam's concerns (following Professor Cash's telephone conversation with Dr McIntyre on 30 December 1986), and consulted with the DHSS and the Treasury, they were able to obtain agreement on a compensation scheme by early February 1987 which, in turn, resulted in clinical trials of Z8 being carried out.

**24.215** There was ample evidence that resolving Professor Ludlam's concerns caused delay. Dr Cuthbertson was of the view that 'there is absolutely no doubt that these concerns delayed the initiation of the clinical trial of Z8. Product was released for use in the trial in December of 1986, but the trial did not commence until March 1987'.<sup>400</sup> He was not critical of Professor Ludlam and other clinicians. He considered that the compensation issues 'were legitimate concerns and that nowadays no clinical trial would be allowed to begin if such indemnity arrangements were not in place'.<sup>401</sup>

**24.216** Professor Cash shared Dr Cuthbertson's view on timing, indicating that the issue caused a delay of 'no more than 3 months'.<sup>402</sup> Professor Ludlam agreed that the issue of compensation delayed Z8's assessment in Edinburgh by about two months. He was not in a position to draw valid conclusions about consequential delay in the introduction of Z8 for clinical use.<sup>403</sup>

**24.217** A separate issue that arises on the evidence is whether delay in commencing clinical trials delayed the availability of Z8 for use by patients.

**24.218** The evidence of witnesses from the SNBTS and the PFC was that, with the exception of previously untreated patients, the delay in commencing clinical trials of Z8 probably did not result in a delay in patients receiving Z8. That was because, in accordance with the batch dedication system, patients already in receipt of NY Factor VIII concentrate (heated at 68°C for 24 hours) would in any event have continued to receive that product until existing stocks were exhausted. Stocks of the intermediate purity NY product did not become exhausted until April/May 1987, by which time Z8 was available for use and began to be prescribed to patients. Even if there had been no delay in resolving the compensation issue and clinical trials had been carried out in late 1986/early 1987, prescription of Z8 to existing patients would still not have begun until existing stocks of NY were exhausted in April/May 1987.

**24.219** Dr Perry's evidence relating to the intention to phase in Z8 to existing patients in accordance with the batch dedication is narrated in paragraph 24.114. Underpinning the arrangement was an understanding among manufacturer and users that successive new products would be introduced through the system to established patients when stocks of the previous product had been exhausted.

**24.220** Given that the batch dedication system reflected established policy, the determining factor which affected the timing of the introduction of Z8 was not when clinical trials of the product were carried out but, rather, the point at which stocks of the PFC's existing 68°C/24 hours intermediate purity NY product ran out.<sup>404</sup> Dr Perry indicated

---

<sup>400</sup> Dr Cuthbertson's statement on Viral Inactivation, 1985–87 [PEN.017.1200] at 1203

<sup>401</sup> Ibid [PEN.017.1200] at 1203

<sup>402</sup> Professor Cash's statement on Viral Inactivation, 1985–87 [PEN.017.1085] at 1088

<sup>403</sup> Professor Ludlam's statement on Viral Inactivation, 1985–87 [PEN.017.1620] at 1623–24

<sup>404</sup> Dr Perry's statement on Viral Inactivation, 1985–87 [PEN.017.1219] at 1254 and his supplementary statement on Viral Inactivation, 1985–87 [PEN.017.2201] at 2203

that this point was reached in April 1987.<sup>405</sup> Therefore, according to Dr Perry, although earlier clinical trials would have relieved some of the PFC's concerns about running out of its existing product before Z8 was ready, importantly, they would not have changed the timescale for the Scotland-wide introduction of Z8.<sup>406</sup> Dr Perry's evidence was that the only patients potentially affected by delay would have been previously untreated patients who were not within the existing batch dedication system and would not have been supplied with the 68°C/24 hours product.<sup>407</sup>

**24.221** During the Oral Hearings both Professor Cash and Professor Ludlam agreed with Dr Perry's evidence that, given the batch dedication system, the key to the introduction of Z8 was exhaustion of the remaining stocks of the PFC's 68°C/24 hours product rather than when Z8 first became available for use by patients.<sup>408</sup> In the case of patients with a significant history of factor concentrate treatment (effectively more than five units) previous exposure to NANB Hepatitis/HCV was assumed. The shift to a new product did not affect their risk of acquiring infection.

**24.222** The rationale for distinguishing previously untreated patients was that they would not already have been exposed to the risk of contracting NANB Hepatitis/HCV from treatment with factor concentrate or cryoprecipitate, and therefore clearly required treatment with a safer product when it became available for use. The evidence available indicated that, but for the delay in resolving the issue of compensation, it is likely that Z8 would have been available for use by previously untreated patients some two to three months earlier than April/May 1987, that is in January/February 1987.

**24.223** Professor Ludlam gave evidence that before releasing Z8 for clinical use it would have been 'necessary to have a stock of several batches, at least enough for 1–3 months' supply<sup>409</sup> and that, in his view, any delay during this period would not have disadvantaged previously untreated patients as these could have had access to 8Y:

If there was a delay of approximately 3 months (Z8 introduced for clinical use in May rather than February 1987) untransfused patients (PUPs), who would have been at risk of non-A non-B hepatitis, could have had access to 8Y (a small stock of which had been acquired in August 1986). Thus patients, therefore, should not have been disadvantaged if there was any delay in the introduction of Z8.<sup>410</sup>

**24.224** The Inquiry is aware of one patient (patient 'Alex') who was first treated with Factor VIII concentrate in mid-January 1987.<sup>411</sup> Otherwise, the Inquiry is unaware whether any previously untreated patients contracted Hepatitis C as a result of treatment with insufficiently heat-treated Factor VIII product between January/February and April/May 1987. The total number of patients first treated between 1 September 1985 and 30 June 1987 was 29.<sup>412</sup> If there are any such patients, other than Alex, who were infected between

<sup>412</sup> See Chapter 22, *Haemophilia Therapy – Use of Blood Products 1985–1987*

about January and April 1987, their number is likely to be very small. It is, however, a matter of considerable regret that any patient was or may have been infected in this period.

**24.225** Professor Ludlam's evidence about availability of BPL 8Y for treatment of PUPs is accepted so far as Edinburgh and south east Scotland patients are concerned. As discussed in Chapter 22, *Haemophilia Therapy – Use of Blood Products 1985–1987*, the Inquiry failed to uncover any evidence suggesting that the availability of 8Y was known to other Haemophilia Directors, or that there were in place appropriate protocols for application to the BPL for release of 8Y for what (at the time) would have been part of an extended clinical trial programme.

***Should the PFC have copied the English 8Y process?***

**24.226** The question arises as to why the PFC did not seek simply to copy the BPL's manufacturing processes for 8Y after the decision was taken in Scotland in late 1985/early 1986 to switch from developing a high purity, pasteurised, product to developing a Factor VIII product that could be severely dry heat-treated. The evidence received by the Inquiry, however, indicated that there were practical reasons why that was not a realistic option and that, if it had been adopted, it is unlikely to have led to the more rapid introduction of a Hepatitis C-safe Factor VIII product in Scotland.

**24.227** Dr Foster explained that in 1986:

The option of directly transferring the methods and technologies used by BPL was not chosen because a number of uncertainties remained, in particular:

- use by BPL of a chemical (heparin) at a concentration which interfered with the routine method used by SNBTS for measuring factor VIII activity,
- uncertainty over the practicality and time required to replace the SNBTS method of measuring factor VIII activity with the method used by BPL,
- uncertainty over the omission of aluminium hydroxide adsorption in the BPL process and the possibility that minor process variations might result in instability to factor VIII,
- difficulties previously experienced by the SNBTS in the use of precipitation/centrifugation to recover purified factor VIII from dilute solutions,
- the need to purchase, install and become familiar with large-scale size exclusion chromatography in factor VIII processing.<sup>413</sup>

**24.228** None of these were trivial matters. When examined on these issues during the Inquiry hearings, Dr Foster explained that the problems outlined above were largely technical in nature and that PFC's judgment was that it would be quicker to use the existing PFC processes:

[T]he question we were faced with was, what could we do most quickly, or what did we think we could do most quickly. And that was the judgment that we made, that we could do it most quickly using procedures we were more familiar with and that were more compatible with our operation.<sup>414</sup>

<sup>413</sup> SNBTS Briefing Paper on the development of heat treatment, November 2010 [PEN.013.1309] at 1351–52

<sup>414</sup> Dr Foster – Day 56, page 127

**24.229** Dr Foster also pointed out that copying the 8Y process would have involved purchasing expensive new equipment, some of which might have had to have been specially designed and which would have required additional requests for funding.<sup>415</sup> According to Dr Foster these issues could have led to delays.<sup>416</sup>

**24.230** A similar point was made by Dr McIntosh, who explained that there were at least eight technical differences between the 8Y and Z8 processes which the PFC would have had to have overcome in order to replicate 8Y, namely:

- Adjustments to cryoprecipitate processing involving the purchasing of different thawing vessels (the 8Y process used simple batch thawing, whereas the PFC used a continuous thin film thawing technique developed by Dr Foster).
- The purchasing of Sharples centrifuges to match those used in England.
- The reconfiguring of the PFC's coolant supply so as to function with the Sharples centrifuges.
- A change to the PFC's assay method so as to deal with the large concentration of heparin involved in the 8Y process.
- The purchasing and commissioning of chromatography columns to replace the PFC's existing ultrafiltration technology.
- The purchasing of new testing equipment to deal with the fact that 8Y was stoppered when in a vacuum.
- The need to add an additional unit operation step, which would have been difficult to fit into the PFC's existing processing time.
- Potential issues as regards the low yield of 8Y, which could have caused difficulties as regards the Scottish policy of self-sufficiency.<sup>417</sup>

**24.231** Dr McIntosh concluded that it would not have been straightforward to copy all the procedures used to manufacture 8Y. In oral evidence, he indicated that it would not have been feasible to pick and choose certain elements from the 8Y process, explaining that:

[N]either Oxford's understanding of their own process nor our understanding of what the key parameters were was sufficiently developed at that time in order to be able to make what would be a very sophisticated judgment to select key parameters from a process and emerge with a process design which would allow severe heat-treating at 80°C, when this was a brand new, hitherto unachieved development.<sup>418</sup>

**24.232** Dr Smith provided an overview of certain difficulties the PFC would have been confronted with in attempting to copy the English 8Y process.<sup>419</sup> These largely mirror those highlighted by Drs Foster and McIntosh and included:

- The fact that the high residual concentration of heparin used in the 8Y process would invalidate the PFC's Factor VIII assay.

<sup>416</sup> Dr Foster – Day 56, page 128

<sup>417</sup> Dr McIntosh – Day 61, pages 71–78

<sup>418</sup> Dr McIntosh – Day 61, page 81

<sup>419</sup> Dr Smith's statement on Viral Inactivation 1985–87 [PEN.017.1130] at 1139

- The fact that there was likely to be an inherent problem of trying to mimic the 8Y methodology and equipment. There would be a risk in any attempt at duplication of the 8Y methodology that it would fail to identify important variables hidden within the existing process and would therefore be unsuccessful.
- The fact that the full scale 8Y process required at least two shifts of skilled operatives, whereas the PFC did not operate shift-working.
- The use of different centrifugation technology.
- The need for the PFC to change to gel filtration from ultrafiltration.
- The relatively low yield of 8Y, which according to Dr Smith was no more than 200 IU/kg.

**24.233** Dr Smith discussed these technical difficulties during the Inquiry hearings,<sup>420</sup> and also explained in more depth the technical reasons why the heparin used in the 8Y process would have interfered with the PFC's existing Factor VIII assay.<sup>421</sup> Dr Smith's general view was that there were very valid scientific, technical and management grounds for not trying to copy the process and that it is only with hindsight that 8Y can be regarded as providing a Hepatitis-safe Factor VIII — or as Dr Smith put it in his written evidence:

It was never a case of, 'Jim Smith has finally smuggled out the recipe for a hepatitis-free F.VIII. Stop everything you have been doing for three years, we start on Tuesday'.<sup>422</sup>

**24.234** Professor Van Aken was asked whether it was reasonable for the PFC to decide to develop its own process in December 1985 rather than simply copying the 8Y manufacturing process and, in his response, stressed that there were technical obstacles which the PFC would have needed to overcome.<sup>423</sup> In addition, he emphasised, in line with other witnesses, that any decision to follow the 8Y process would have had to have been an 'all or nothing' decision, encompassing all aspects of the process. According to Professor Van Aken:

You cannot say, 'I'll just take this step and the rest I will continue', as you used to do so. You have to do it all or not to do. That is usually the experience, that you cannot, without getting into all sorts of surprises, just say, 'Well, I'll use this element and this element, and the rest I'll leave as it is'.<sup>424</sup>

**24.235** Overall, the evidence before the Inquiry was to the effect that it was reasonable for the PFC to decide not to attempt to copy the English 8Y process but, rather, to seek to develop their own Factor VIII product that could be severely dry-heated, using their own manufacturing processes and plant and building on their existing research work. That evidence is accepted.

---

<sup>420</sup> Dr Smith – Day 60, pages 84–96

<sup>421</sup> BPL/PFL used a so-called 'two-stage' assay whereas PFC used a 'one-stage' assay. The increased sensitivity of the two-stage assay meant, in practice, that heparin was less likely to interfere with the result. For more details see Dr Smith – Day 59, pages 97–109 and also Dr Foster – Day 56, pages 15–18

*Liaison between fractionators in Scotland and England*

**24.236** Communication between the PFC and the PFL/BPL was from time to time inhibited by confidentiality agreements with third parties or by the need to avoid disclosure of patentable inventions. Otherwise, the evidence available to the Inquiry was uniformly to the effect that liaison between the organisations, although mainly conducted informally, was effective in ensuring that researchers in Scotland were aware of significant developments in England and that the sharing of information between fractionators in each facility did not lead to any delay in the development and production of a Hepatitis C-safe Factor VIII product in Scotland.

**24.237** As regards awareness in Scotland of the development of 8Y, for example, Dr Foster explained in his written evidence that he first became aware of the work by the PFL in May 1984 when a letter from Dr Smith alerted him to ‘an intriguing alternative to zinc [precipitation]’<sup>425</sup> (ie the heparin discovery outlined above) and that by late November 1984 he was generally aware of the procedures used in the preparation of 8Y, most probably as a result of informal discussions between Dr McIntosh (PFC) and Mrs Winkelman (PFL) which were communicated to him.<sup>426</sup> Dr Foster’s witness statement also indicated that he was aware at the end of 1984 that, ‘the ability of 8Y to withstand heating at 80°C for 72 hours was believed by Dr Smith and Mrs Winkelman to be due to the higher degree of purification of factor VIII that was obtained by the 8Y process’.<sup>427</sup> He also explained that Mrs Winkelman and colleagues from the PFL/BPL visited the PFC on 27 March 1985 to discuss heat treatment and that she indicated that a final decision had yet to be taken on whether to dry heat the established BPL Factor VIII (ie HL mentioned above in paragraph 24.15) at 70°C for 24 hours or 8Y at 80°C for 72 hours.<sup>428</sup> Dr Foster also explained that he received a copy of the patent application for 8Y from Dr Smith on 16 April 1985.<sup>429</sup> According to Dr Foster, it was not, however, until sometime in late summer 1985 (he did not know precisely when) that he learned that the PFL’s 8Y process had been successfully scaled-up and transferred to the BPL.<sup>430</sup>

**24.238** Dr McIntosh confirmed in his written evidence that the SNBTS/PFC were aware of the major features of the 8Y process prior to receiving a copy of the patent application for 8Y in 1985.<sup>431</sup> During the Inquiry’s hearings Dr McIntosh indicated that he thought that he would have learned of the PFL’s 8Y process in late 1984.<sup>432</sup>

**24.239** When specifically asked about the adequacy of the liaison arrangements, Dr Foster advised that, from his perspective, communications between the SNBTS and the BPL/PFL were ‘excellent’ and involved not only himself and Dr Smith, but included: Dr Pepper (SNBTS Headquarters Laboratory) with Dr Smith; Dr McIntosh (PFC R&D) with Mrs Winkelman and Mr Evans (PFL R&D scientists); Dr Cuthbertson (PFC Head of Quality) with Dr Snape (BPL Head of Quality); and Dr Perry (PFC Director) with Dr Smith and Dr Snape.<sup>433</sup>

<sup>425</sup> Dr Smith’s letter to Dr Foster of 22 May 1984 [SNB.007.4402]

<sup>426</sup> For Dr Foster’s statement and more details of when Dr Foster became aware of PFL’s research into 8Y – including the various documents communicated to the PFC. See Dr Foster’s statement on Heat Treatment, 1985–1987 [PEN.017.1556] at 1556–59 See also Dr Foster – Day 56, pages 20–21

<sup>431</sup> Dr McIntosh’s statement on Viral Inactivation 1985–1987 [PEN.017.1234] at 1234

<sup>432</sup> Dr McIntosh – Day 61, page 15

<sup>433</sup> Dr Foster’s statement on Heat Treatment, 1985–1987 [PEN.017.1556] at 1567–68

**24.240** Drs Perry, Cuthbertson and McIntosh also considered that there were good relations, and a satisfactory exchange of information, between fractionators north and south of the border.<sup>434</sup>

**24.241** For his part, Dr Smith of the PFL/BPL indicated that while there was tension at senior (ie Director) level (at least, in the period before Dr Perry became Director at the PFC), that did not hinder fruitful co-operation between scientists or in relation to research.<sup>435</sup>

**24.242** On his reading of the available documentation, Professor Van Aken formed the view that 'there does not appear to have been a lack of shared information which might have impeded the progress of developing heat treated Factor VIII by PFC'.<sup>436</sup>

**24.243** Professor Cash initially provided written evidence to the effect that, in his view, improvements in liaison between the BPL and the PFC were desirable and that it was his belief that had the two organisations been able to pool their limited research and development resources, and perhaps some manufacturing resources, it may have made a significant difference, throughout the 1980s, to the availability of desirable plasma products in the UK.<sup>437</sup> This was explored further during the Inquiry hearings when Professor Cash was asked whether any difficulties between the directors of the BPL and the PFC adversely affected the PFC's work on coagulation factors (in particular Z8). Professor Cash agreed that he would defer to the views of Drs Foster and Cuthbertson that such difficulties did not affect their work, albeit he remained of the general view that there were advantages to more formal arrangements for the exchange of research information.<sup>438</sup>

**24.244** Dr Perry acknowledged that there was an absence of a formal management structure providing a link between the PFC and the BPL, but considered that there were many examples of 'highly productive collaboration'. In the case of Factor VIII, in his view it could perhaps be argued that the lack of formal arrangements was beneficial as it allowed the BPL and the PFC to concentrate on different research and development strategies in the period up to 1985 (ie dry heat treatment and pasteurisation respectively) rather than being forced to back one process which may or may not have been successful.<sup>439</sup>

**24.245** This evidence is accepted. There was ample circumstantial evidence illustrating the extent of cooperation, if seldom actual collaboration, between responsible officers of the two organisations in the exchange of data and of their experimental and development findings. The SNBTS was unable to disclose confidential information obtained from Professor Johnson of New York University under contract. Dr Smith and Mrs Winkelman on the one hand, and Dr Foster and his colleagues on the other were inhibited from time to time by the need to avoid prior disclosure of the inventive steps in processes that were or were intended to be subject of patent applications. The narrow scope of the exceptions is consistent with what otherwise was an open exchange of scientific and technical knowledge. It appears to be clear that this openness was not a characteristic of relationships between senior management of the organisations, but there was no evidence to suggest that there were consequential difficulties among scientists.

***Why the PFC was able to produce severely dry heat-treated Factor IX (DEFIX) earlier than severely dry heat-treated Factor VIII (Z8)***

**24.246** The PFC released heat-treated Factor IX (HT DEFIX, dry-heated to 80°C for 72 hours) in October 1985, whereas Z8 Factor VIII (also dry-heated at 80°C for 72 hours) was not available for clinical trials until December 1986, over a year later.

**24.247** The question was not, in the event, controversial and can be dealt with briefly. Factor IX was more stable than Factor VIII and, because of its chemical composition, inherently less likely to be damaged by heating. For these reasons the heat treatment of Factor IX posed far less of a technical challenge than the heat treatment of Factor VIII.<sup>440</sup> In addition, the heating of Factor IX, unlike heating Factor VIII, did not give rise to any yield constraints.<sup>441</sup> Both the PFC and the PFL/BPL had potential problems arising from the risk of thrombogenicity in their heat-treated products. Solving these was a rather singular example of active collaboration between the two services. The SNBTS had access to the facilities necessary for dog studies to determine the risk of thrombogenicity. In the event the collaboration was successful. All technical problems were overcome relatively quickly.

**24.248** On the evidence available, the differences between the products were such that there cannot be meaningful comparison between them in terms of the course of research and development required to resolve the issues raised by heat treatment, or in terms of the time required to reach a solution. That evidence is accepted.

## **Conclusions**

### ***Development of Z8***

#### **Priority of research into pasteurisation**

**24.249** Until it was established that the processing of PFL/BPL's 8Y Factor VIII concentrate was effective to inactivate HIV and NANB Hepatitis/HCV in source plasma, there was no scientific basis for a decision to prefer dry heat treatment over pasteurisation in the manufacture of factor concentrates.

**24.250** Commercial pharmaceutical companies which had developed and marketed dry heat-treated products in the first half of the 1980s<sup>442</sup> changed to pasteurisation or solvent/detergent methods of virus inactivation in products marketed in the second half of the 1980s and early 1990s.<sup>443</sup>

**24.251** The PFC's research aimed at production of a pasteurised product effective to inactivate HIV and NANB Hepatitis/HCV was consistent with accepted industry norms, and, if it had been pursued, would have continued to be consistent with wider industry expectations related to dry heat-treated products, without exception, until early 1988.<sup>444</sup>

<sup>440</sup> Dr Foster's statement on Heat Treatment, 1985–1987 [PEN.017.1556] at 1572; Dr Cuthbertson's statement on Viral Inactivation, 1985–1987 [PEN.017.1200] at 1207; Dr McIntosh's statement on Viral Inactivation, 1985–1987 [PEN.017.1234] at 1242; Dr Perry's statement on Viral Inactivation, 1985–1987 [PEN.017.1219] at 1230

<sup>441</sup> Dr McIntosh's statement on Viral Inactivation, 1985–1987 [PEN.017.1234] at 1242

<sup>442</sup> See Appendix 1 to Chapter 23, *Viral Inactivation of Blood Products for Haemophilia Therapy up to 1985*

<sup>443</sup> Paragraph 24.4 and Tables 24.1 and 24.2 above

<sup>444</sup> The earliest third party support for 8Y found by the Inquiry is a letter dated 29 February 1988, written from the New England Medical Centre Hospitals, Boston, USA to BPL Elstree, asking BPL to apply for US FDA approval of the BPL process for 8Y. The medical centre expressed the view that BPL factor 8Y was the safest concentrate available. [DHF.002.8088]

**24.252** The PFC's decision to change direction, formalised in January 1986, reflected:

- Privileged information about the development of 8Y available to the PFC as a result of informal collaboration between scientists at the PFL/BPL and the PFC respectively.
- Dr McIntosh's discovery that the experimental control sample of PFC's standard Factor VIII concentrate withstood heating at 80°C for 72 hours.
- The insight that purity was not critical to the ability of Factor VIII to withstand heating at high temperature and for prolonged periods.
- Highly innovative research that disclosed the critical role of the crystal structure of the frozen product in making it suitable for heating at high temperature.

**24.253** The random selection of a control sample that had a uniform fine crystal structure may have introduced an element of serendipity into Dr McIntosh's experiment: that is of the nature of invention.

**24.254** It is also of the nature of invention that until the factors contributing to an inventive insight come together speculation about what might have been until that point is idle. One cannot anticipate invention.

**24.255** The PFC's research into pasteurisation was fully justified, and was appropriate, having regard both to comparative industry practice and the progress achieved down to the end of 1985.

**Should the PFC have decided to develop a Factor VIII concentrate that could be severely heat-treated earlier than it did?**

**24.256** The only support for dry heat treatment of Factor VIII in the mid-1980s was the success of the PFL/BPL in developing 8Y.

**24.257** That was (erroneously, as it turned out) understood in Scotland until the end of 1985, and in England until at least the end of 1986,<sup>445</sup> to have depended on having a high purity product.

**24.258** The PFC devoted considerable time and resources in 1984 and 1985 to research and development of a high purity Factor VIII product, initially ZHT and later NYU.

**24.259** According to the perceptions of the period, high purity was a necessary preliminary step towards any form of effective heat treatment.

**24.260** ZHT was not fully developed by the end of 1985 when Dr McIntosh's discovery was made.

**24.261** In short, there is no factual basis for any suggestion that the PFC should have decided to develop a Factor VIII product that could be severely heat-treated earlier than it did.

---

<sup>445</sup> See paragraph 24.72; Dr Smith's letter to Dr Foster dated 8 December 1986 on the effects of plasma conditioning: [SNB.007.6275] and [SNB.007.6276]

**Progress towards clinical trials following the decision to develop a dry heat-treated product (Z8): research and development by SNBTS**

**24.262** The PFC applied appropriate resources in the research and development work necessary to achieve an acceptable Factor VIII product dry heat-treated to inactivate HIV and NANB Hepatitis/HCV.

**24.263** Z8 was developed and made ready for clinical trials within a reasonable time.

**24.264** Professor Van Aken's assessment of the success of the PFC as 'quite an achievement' is accepted.

**24.265** There is no basis for adverse criticism of the work of the PFC in this respect.

**Progress towards clinical trials following the decision to develop a dry heat-treated product (Z8): compensation**

**24.266** The demand by Haemophilia Directors (and Professor Ludlam in particular) for appropriate provision for compensation for individuals who agreed to undergo trials of and treatment with Z8 before licensing of the product was in the interests of patients and was reasonable.

**24.267** The demand was limited in scope and could and should have been dealt with on its own merits with reasonable expedition.

**24.268** The demand raised issues of health policy and funding which were not within the scope of CSA's delegated functions. The CSA was not equipped to deal with issues involving clinical judgement. The CSA was unlikely ever to have been an appropriate body to resolve such issues within its own budgets and competency.<sup>446</sup>

**24.269** The commitment of resources for compensation ought to have been dealt with by the SHHD from the outset in consultation with the Treasury.

**24.270** Failure to address the specific issue with reasonable expedition resulted in the delay of clinical studies and the resultant availability of Z8 for therapy for PUPs by three months.

**24.271** Because of policy decisions related to batch dedication the delay of clinical studies did not affect established patients.

**Should the PFC have copied BPL's 8Y process?**

**24.272** Manufacturing technology and process equipment employed by the PFC and the BPL respectively were not compatible in eight distinct technological areas.

**24.273** In particular, assay procedures for the monitoring of Factor VIII levels during processing, integral to manufacturing, were incompatible, with the BPL using a unique procedure that could not be accommodated by the PFC.

**24.274** Piecemeal adoption of elements from the BPL's integrated manufacturing processes was not a viable option: there was an unavoidable risk of incompatibility.

**24.275** Wholesale adoption of the BPL's 8Y process would have been problematical for the reasons given by Dr Smith: idiosyncratic variables 'hidden' within the BPL's process might not be identified with the result that the PFC could not duplicate the process effectively.

---

<sup>446</sup> See Chapter 17, *Blood and Blood Products Management*, paragraphs 17.24–17.27 and 17.50–17.57

**24.276** The previous point was validated by events. The discovery of the criticality of the crystal structure of the frozen product in vial in the course of processing, and of the importance of plasma conditioning, factors that had not been identified by the PFL/BPL, brought to light idiosyncratic features of the English process that might not have been discovered in time to avoid delay in Scotland.

**24.277** The process of specifying, purchasing and commissioning new equipment would have been time-consuming and expensive and uncertain of success.

**24.278** Modification of the PFC's existing technology was the preferable approach.

**24.279** It was not demonstrated on the evidence that the PFC should, or could, have attempted to mimic the BPL's 8Y process.

### *Summary*

- There is no basis for adverse criticism of the PFC and its scientists over the period ending with the introduction of Z8 for routine clinical use in April 1987. On the contrary, they achieved outstanding results, as evidenced by the fact that Scotland appears to have been the first country in the world that was able to supply all of its haemophilia patients with a Factor VIII product that did not transmit Hepatitis C.
- After the introduction of Z8, research and development work proceeded on new, purer, products to meet changing demands from clinicians. However, safety from transmission of virus had been achieved, and later developments, while demonstrating the SNBTS's commitment to improving quality of products, did not produce safer products.
- Administrative delays by the SHHD in dealing with the Haemophilia Directors' demands for compensation arrangements for patients adversely affected by new products prior to regulatory approval resulted in delay of about three months in trials and availability of Z8.
- However, the only adverse impact on the safety of patients was the unavailability of Z8 during that period of delay for the treatment of virgin and infrequently treated patients.

## CHAPTER 25

### SCREENING OF DONATED BLOOD FOR HEPATITIS B

#### Introduction

**25.1** Before the discovery of the 'Australia' (or 'hepatitis-associated') antigen, later renamed the Hepatitis B surface antigen (HBsAg), there were few, if any, settled Scottish National Blood Transfusion Service (SNBTS) protocols to guide practice at donation sessions. Individual Regional Transfusion Directors (RTDs) were free to develop and apply their own policies and practices for the protection of recipients of blood, blood components and blood products from transmission of infection. In the early 1970s, the risk of transmission of viral hepatitis, so far as it was understood, was thought to be mitigated by what were regarded as increasingly sophisticated screening tests for the Hepatitis B virus (HBV) antigen and antibody and these became the main means of protecting the blood supply.

**25.2** In this chapter those tests are discussed in an attempt to understand their development and the reliance placed on them at the time. There is no clear end date for the chapter. By the autumn of 1983, attention was moving from non-A, non-B Hepatitis (NANB Hepatitis) to AIDS<sup>1</sup> and the period selected for discussion ends with the emergence of AIDS, growing awareness of the need for protocols on donor selection in that context and implementation of the first structured guidance on donor selection in Scotland. By then a view had emerged that NANB Hepatitis was not a major problem in Scotland and was generally not a serious disease. That view persisted into the late 1980s. Screening for HBV continued, with increasing sophistication, but also with increasing awareness that the results were of little relevance to NANB Hepatitis.

**25.3** Historically, the blood collection procedures followed in Scotland in the course of routine donation sessions provide a context for discussing the impact of screening technology and practice. As discussed in Chapter 18, *Collection of Blood – General*, at the beginning of the reference period those procedures were not well adapted to investigating the health or relevant social factors affecting the prospective donor's suitability to provide blood for transfusion; they relied heavily on volunteered information. In some circumstances, as in collections in prisons, there was particular concern about the reliability of the information provided. Chapter 26, *Donor Selection – Higher Risk Donors*, discusses some groups of individuals who might have been thought to be unsuitable as donors and the methods adopted to identify members of these particular groups. Apart from interview and visual inspection of prospective donors, emphasis was placed on developing scientific tests to identify blood donations that presented risk and the approach to routine collection procedures can best be understood against that background.

#### *Developing knowledge of Hepatitis B and growing awareness of other hepatitis viruses*

**25.4** The effectiveness of an approach that relied heavily on technology depended in the first place on knowledge of the risk against which the tests were directed and, secondly, on the relevance of the test results to total risk, as knowledge of the range of infective agents increased. It became increasingly clear from seminal research during and after

---

<sup>1</sup> See, in particular, Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*, and the discussion of the work of the Working Party on Transfusion Transmitted Hepatitis below.

the mid-1970s that tests developed to identify the Hepatitis B antigen or antibody – the primary technology available – did not detect antigen or antibody associated with NANB Hepatitis viruses which were, by definition, different but as yet uncharacterised. The risk of transmission of NANB Hepatitis could not be managed by testing: whether the risk of transmission of those forms of infection was acceptable was thought to depend on the materiality of the risk to the patient (that is, the severity of the disease) as understood from time to time.

**25.5** Knowledge of the natural history of Hepatitis B developed during this period but was not fully understood by the end of it.<sup>2</sup> As was to happen later, following the discovery of the Hepatitis C virus (HCV), it took some years for researchers to match the markers of infection to the liver histology (appearance of liver cells under a microscope) and clinical picture presented by the patient and to the natural history of the disease. By the end of the period, it was known that the Hepatitis B virus damaged the liver cells it invaded and that, at least in the early stages of infection, it was more damaging than the postulated NANB Hepatitis virus(es). A higher proportion of acute Hepatitis B patients had overt clinical illness and jaundice. These signs and symptoms reflected the body's immune response to the virus, proportionate to the virus' attack, and usually would lead to clearance of the virus (in dead liver cells) and, if the virus was completely cleared, regeneration of the liver and restoration of normal liver architecture and function.

**25.6** The vast majority of patients with haemophilia who had overt jaundice in the late 1960s and early 1970s did have acute Hepatitis B. A proportion of these patients went on to have chronic liver disease, marked by persistently elevated transaminases,<sup>3</sup> and it was initially thought that these biometric indications were related to their Hepatitis B infection. By the early 1980s, however, it was increasingly understood that most of these patients probably were infected, or co-infected, with NANB Hepatitis. Many had cleared the Hepatitis B virus and recovered from that disease. Their continuing abnormal liver enzyme levels, indicative of liver disease, were due to NANB Hepatitis infection and, in most of those cases at least, as events were to prove, Hepatitis C infection.

**25.7** Clinically, there are similarities between the types of infection. Most chronic HBV infections, like infections with NANB Hepatitis/HCV, are insidious, with no obvious acute clinical onset. Also like NANB Hepatitis/Hepatitis C, Hepatitis B acquired in infancy is usually chronic but does not present with any symptoms until the patient is aged in the 30s or later. In each case, infection acquired in later life (over about 50 years of age), if chronic, often progresses to cirrhosis in relatively short periods compared with the 20, 30 or more years typical in younger patients. Both diseases are, however, associated with long periods of developing fibrosis (scarring of the liver) before the stage of cirrhosis is reached. Progression to cirrhosis indicates that not only is there significant fibrosis but also that the normal architecture of the liver has changed to include structurally abnormal nodules. Like NANB Hepatitis/Hepatitis C, a small proportion of carriers of Hepatitis B appear to be 'tolerant' of infection. The virus circulates, and the patients are still carriers of the infection and remain infectious to others, but it never does the 'tolerant' patient any harm.

---

<sup>2</sup> See Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985* and, in particular, the successive editions of *Diseases of the Liver and Biliary System* by Dame Sheila Sherlock referred to therein.

<sup>3</sup> Typically alanine transaminase (ALT), a protein synthesised in liver cells. Normally present in low levels in the blood, ALT becomes elevated when the liver is disordered.

**25.8** As discussed in Chapter 14, *Knowledge of Viral Hepatitis 1*, the existence of NANB Hepatitis was inferred from observation of hepatitis in patients shown by the best tests available not to have Hepatitis A, Hepatitis B, cytomegalovirus or Epstein-Barr virus infection. Although a test for Hepatitis A was reported in 1973, a screening test for practical application was not available in Scotland until 1978.<sup>4</sup> The Hepatitis B tests available developed and changed over the period are covered in this chapter. From the outset there were tests for Hepatitis B surface antigen (HBsAg) and Hepatitis B surface antibody (anti-HBs). The HBsAg tests indicated whether the patient was currently infectious and might indicate ongoing chronic Hepatitis B liver disease. The anti-HBs test indicated that the patient had been exposed to or infected by Hepatitis B. If HBsAg was absent (and occasionally the two might co-exist) then a positive test for anti-HBs indicated that the patient had previously had Hepatitis B but was now immune and, in the absence of HBsAg, was no longer infectious.

**25.9** These tests improved in sensitivity during this period and additional tests were also developed. In the 1980s, tests for the presence of antibody to Hepatitis B core antigen (anti-HBc) were developed, which added to knowledge of the state of infection in patients.<sup>5</sup> Combining the results of the additional tests with a negative HBsAg test, for example, could provide a reliable indicator of past infection and confirm the absence of current infection. Alternatively, where HBsAg had 'faded' from serum, as it might over time, the additional tests could indicate current infectivity (usually chronic) and show that the Hepatitis B virus was still present in the body, even if only in very small amounts.

**25.10** As these tests relating to Hepatitis B developed in sophistication and in sensitivity, with growing knowledge of the structure of the Hepatitis B virus well into the 1980s, appreciation of the prevalence of NANB Hepatitis/Hepatitis C increased, and increased knowledge of the implications of infection with the Hepatitis B virus (or group of viruses)<sup>6</sup> became better understood. It is important to bear in mind, however, in considering comments made as the period progressed, that understanding of the absolute and relative reliability of tests also increased over the period. Confidence in the effectiveness of Hepatitis B screening assays to identify blood with the potential to transmit 'viral hepatitis', at least until the early to mid-1980s, reflected a lack of understanding both of the efficiency of the technology in identifying Hepatitis B and of the characteristics of NANB Hepatitis that undermined the usefulness of available screening tests more generally. Comments made early in the period may mislead in presenting an apparent state of knowledge of matters that in fact were established only at a later date.

**25.11** The 1973 World Health Organization (WHO) report of the opinions of the expert scientific group on viral hepatitis, discussed in Chapter 14, *Knowledge of Viral Hepatitis 1*, paragraphs 14.31–14.42, commented that it was generally agreed that not all cases of post-transfusion hepatitis were caused by Hepatitis B infection and that 'as more hepatitis B carriers are eliminated from serving as blood donors, the proportion of cases

<sup>4</sup> See paragraph 25.74 below.

<sup>5</sup> Tests for anti-HBc were supplemented by tests for the antigen using specific immunoglobulins, Immunoglobulin M (IgM) and Immunoglobulin G (IgG). The test for anti-HBc became of interest as a possible 'surrogate marker' for NANB Hepatitis and is discussed in that context in Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*. The anti-HBc and IgM tests indicated whether the patient had ongoing infection. The IgG test indicated whether the patient had been exposed to or infected with Hepatitis B. It is not necessary, for present purposes, to discuss the nature of these tests in detail.

<sup>6</sup> As with HCV (see Chapter 13, *Knowledge of Viral Hepatitis Now*, paragraph 13.14), HBV is divided into a number of different genotypes (and subgenotypes) with distinct properties.

due to other types of hepatitis will increase'.<sup>7</sup> The comment was speculative, however: the seminal research that led to the conclusion that there were types of viral hepatic disease other than Hepatitis A and B had not yet been published. In a section on 'Changing patterns of infection in certain developed countries', the report noted marked shifts in the age- and sex-specific rates for hepatitis in the USA and some European countries during the previous decade. The patterns of infection noted were not related to blood transfusion or other medical procedures but, rather, suggested a likely association with the illicit use of drugs. It was thought quite possible that, in addition to the increased risk of parenteral transmission,<sup>8</sup> the lifestyles of drug users might increase the level of non-parenteral transmission.<sup>9</sup> The population groups exposed to infection were increasing and the scientific context for the objective testing of blood for agents that might transmit infection was widening. The risks of transmission were accordingly increasing in the absence of effective exclusion policies and practices. In the early and mid-1970s, however, practical steps for eliminating post-transfusion hepatitis were still focused on Hepatitis B and testing for that infection in particular.

### The demand for a serological test for Hepatitis B

**25.12** The need for screening for hepatitis had been identified at an early date, sometimes generally but more often related to Hepatitis B. In November 1969, a letter to the *British Medical Journal (BMJ)* reflected a general view:

[U]ntil a reliable serological test for viral hepatitis is available the donor with anicteric hepatitis [hepatitis, that is, that does not present with clinical jaundice] will go undetected. Cryoprecipitate will remain a potential source for the transmission of hepatitis virus until previous attacks of this form of hepatitis can be reliably diagnosed or an effective means of sterilization ... is produced.<sup>10</sup>

**25.13** At a meeting of the UK RTDs on 15 October 1969, a contributor from the London School of Hygiene and Tropical Medicine (name redacted but almost certainly Professor Arie Zuckerman) presented a talk on the discovery of the Australia antigen, on methods of detecting it and on its possible relationship with serum hepatitis.<sup>11</sup> In discussion it was agreed that there were few reported cases of Hepatitis B transmission and none of other viral hepatitis transmission in major surgery. Six cases of viral hepatitis transmission related

<sup>7</sup> The group met in Geneva on 25–30 September 1972. Their report, dated 1973, was published in 1975 as 'Viral Hepatitis: Report of a WHO Scientific Group', *World Health Organization technical Report Series*, No. 512 [SGH.002.9746] at 9754. See, also, at 9762 where it was noted that '[t]he present widely employed techniques for detecting Hepatitis B antigen in blood are thought to be capable of preventing approximately 30% of cases of post-transfusion hepatitis. The effect the introduction of more sensitive techniques will have on the rate of post-transfusion hepatitis is not yet clear, but preliminary evidence suggests that it will not be great... Cases not due to virus B are thought to be due to a variety of causes, including Hepatitis A virus, cytomegalovirus, and other, as yet unidentified agents'. See, also, Dr McClelland – Day 9, pages 106–108

<sup>8</sup> Parenteral transmission typically refers to a blood-borne route of transmission. See Chapter 13, *Knowledge of Viral Hepatitis Now*, footnote 5 for a fuller discussion of the term.

<sup>9</sup> 'Viral Hepatitis: Report of a WHO Scientific Group', *World Health Organization Technical Report Series*, 1975; No. 512 [SGH.002.9746] at 9755. Strictly speaking, an enteral infection is one spread through the introduction of a pathogen to the gastrointestinal tract. A parenteral infection is one spread by a means other than by the introduction of a pathogen to the gastrointestinal tract and, in this general way, does not refer only to blood-borne infections. Medical literature of the time, however, used the term parenteral, at least as regards hepatitis, to mean 'blood-borne' and this usage is retained here.

<sup>10</sup> Fitzpatrick and Kennedy, 'Serum hepatitis in a haemophilic', *British Medical Journal*, 1 November 1969; 299 [LIT.001.0249]

<sup>11</sup> Minutes of meeting [DHF.002.7801]. At this period the expressions 'Australia/Australian antigen' (Au), 'Hepatitis Associated Antigen' (HAA), and 'Australian (Hepatitis Associated) Antigen' are used interchangeably, all superseded by the term 'Hepatitis B surface antigen' (HBsAg). See the second report of the Maycock Advisory Group, [SGH.003.0079] at 0083, for a wider range of terminology. In this chapter, 'Australia antigen' and 'Hepatitis B surface antigen /HBsAg' are used, except where it facilitates cross-reference to a source of evidence to use an alternative. See Chapter 14, *Knowledge of Viral Hepatitis Now*, for a discussion of the term 'serum hepatitis' (and the associated term 'infectious hepatitis' referred to below).

to transfusions of cryoprecipitate, not apparently due to Hepatitis B, had been reported to the Oxford Haemophilia Centre.<sup>12</sup> Testing for the presence of Australia antigen required serum samples containing antibody reacting with the antigen ('anti-sera' or 'reagents'). At that stage, only a handful of such samples had been detected in the UK and testing was therefore largely dependent on gifts of reagents from colleagues in the USA.

**25.14** The introduction of tests for the Australia antigen was discussed at the UK RTD meeting on 11 March 1970:

There were several aspects of the problem which would affect any decisions made regarding the general introduction of tests for this antigen: (i) Although the antigen appears to be associated with serum hepatitis and not with infectious hepatitis, it has not yet been shown to be the cause of the former disease although a causal association seems very probable. (ii) If all donors were screened and those with positive tests for Australia antigen were removed from the panel, it was estimated that the incidence of hepatitis might be diminished by about 40 per cent (iii) the antibody containing anti-sera (at present all of human origin) necessary for testing were scarce, of varying potency and possibly of differing specificity (iv) the most reliable method of detecting the Australia antigen was not yet established, (v) the overriding need was to obtain supplies of anti-sera, preferably of animal origin and to establish a reference preparation of anti-serum.<sup>13</sup>

**25.15** The meeting agreed that, in the circumstances, a more precise definition of the status of the Australia antigen and of the methods of detecting it should be awaited before planning to screen donors and also that, if routine testing were to be introduced, it should be on a national (UK-wide) basis because of the possible medico-legal significance of the procedure. Extracts from the minutes of the meetings on 15 October 1969 and 11 March 1970 were later appended to the minutes of the first meeting of the Medical Research Council (MRC) Working Party on Post-Transfusion Hepatitis on 14 February 1980.<sup>14</sup>

**25.16** There had been significant international public health interest in the screening of blood for hepatitis infection before the reference period, but also a great deal of uncertainty. The uncertainty in the UK, and in Europe as a whole, was reflected in a paper presented to the sub-committee of specialists on blood problems of the Public Health Committee of the Council of Europe in April 1970.<sup>15</sup> The paper noted a close association between hepatitis and the Australia antigen but commented that a similar close association between hepatitis and the relative antibody was less well established. The paper stated:

Because of the obvious implications ... it should be considered whether introduction of routine screening should not be deferred until more is known about the nature of the antigen or antigens and the corresponding antibody or antibodies and their relationship to hepatitis.<sup>16</sup>

<sup>12</sup> Minutes of MRC Working Party on Post-Transfusion Hepatitis, 14 February 1980 [DHF.002.4845] at 4846

<sup>13</sup> Minutes of UK RTD meeting [DHF.002.7782] at 7786

<sup>14</sup> Minutes of MRC Working Party on Post-Transfusion Hepatitis, 14 February 1980 [DHF.002.4845] at 4849–50

<sup>15</sup> Paper [DHF.001.1745]

<sup>16</sup> Ibid [DHF.001.1745] at 1746

**25.17** There were technological and practical difficulties in the way of universal screening, according to that advice. In April 1970, however, the burden of the advice submitted to the sub-committee was uncompromising: donations should be tested by effective methods of screening when supplies of antisera were assured and infected blood should not be used. A 1970 WHO bulletin similarly recommended the detection and exclusion of blood donors carrying Australia antigen.<sup>17</sup>

**25.18** The major Scottish Blood Transfusion Centres in Edinburgh and Glasgow were engaged in research into screening tests in 1970. Systematic study of virus transmission by therapeutic blood products had begun in Edinburgh in the 1960s while in Glasgow research was a direct response to the WHO bulletin.<sup>18</sup> In each case the available tests were found to be lacking in sensitivity<sup>19</sup> for detection of the Australia antigen.

**25.19** The published sources, and indeed the Scottish research, appear to have left open a number of questions. The Council of Europe report recognised, in common with other contemporaneous opinion, that the available testing methods would not detect all Hepatitis B antigen-positive donations. Anticipating a point that was to be developed later, as tests became more sensitive, among the patients found negative on the Australia antigen test there would be an increasing proportion of hepatitis caused by 'other' transmissible agents in infected blood samples. It appears to have been clearly understood that there was no assay to detect these groups: other means would have to be relied upon.

**25.20** The problem of reducing the risk of transmission of the Australia antigen by blood and blood derivatives was discussed at a meeting convened by the Department of Health and Social Security (DHSS) on 20 July 1970, where competing views were noted.<sup>20</sup> One view was that screening should be introduced as and when possible, notwithstanding that the methods and reagents used would not be uniform. The other was that attempts to institute screening should not be pressed until much more was known about the Australia antigen and methods of testing for it; and that routine screening should not be introduced except on a national scale with uniform methods of testing and reagents. After extensive discussion, in which it was suggested by one participant that donors whose blood contained antigen or antibody should be permanently excluded from donation, it was recommended that the DHSS should facilitate in every way it could the testing of blood donations for the presence of the Australia antigen and its antibody. The discussion concluded:

As long as antisera for testing were scarce it would not be possible to organize testing on a national scale. The Department might therefore consider starting testing in a few centres ... to test the feasibility of routine screening .... It was agreed that each donation from a given donor should be tested and that the donor should be excluded if antigen or antibody were found. At present it seemed that such a donor should be permanently excluded.<sup>21</sup>

<sup>17</sup> See Wallace et al, 'Total screening of blood donations for Australia (hepatitis associated) antigen and its antibody', *British Medical Journal*, 11 March 1972 [SGH.002.9831]

<sup>18</sup> Chapter 14, *Knowledge of Viral Hepatitis* 1, paragraph 14.59

<sup>19</sup> 'Sensitivity' is a function of the test's ability to capture all cases of infection with the target pathogen. 'Specificity' is a function of the test's ability to identify only the target pathogen.

<sup>20</sup> Note of DHSS meeting [DHF.001.1751]

<sup>21</sup> *Ibid* [DHF.001.1751] at 1755

**25.21** In the light of this recommendation, a further group was set up by the DHSS, the Scottish Home and Health Department (SHHD) and the Welsh Office in September 1970 under the chairmanship of Dr William Maycock: the Advisory Group on Testing for the Presence of Australia (hepatitis-associated) antigen and its antibody (the Maycock Group). Its terms of reference were:

To advise the Health Departments on:

- i the organisation of and responsibility for testing blood donations and other specimens of blood for Australia (hepatitis-associated) antigen and its antibody in the hospital service;
- ii the provision of reagents, choice of methods and whether, and if so, what kind of, training facilities are required;
- iii the scale of accommodation, staffing, equipment and other services necessary to implement the group's proposals.<sup>22</sup>

**25.22** The Maycock Group held its first meeting on 5 October 1970.<sup>23</sup> By then, partial screening of donations had already started in some regions. In the Glasgow and the West of Scotland RTC, partial testing was introduced for a six month period in 1970<sup>24</sup> and was implemented in full in the region on 13 October 1970.<sup>25</sup> In a note of discussions with a commercial supplier dated 10 November 1970, it was recorded that commercial supplies of anti-serum for testing were available.<sup>26</sup>

**25.23** The first report of the Maycock Group was available (probably in draft) in September 1971.<sup>27</sup> It recommended that Regional Transfusion Centres (RTCs) should begin testing at the earliest possible date using immunodiffusion, complement fixation or immunoelectro-osmophoresis technology at the Director's discretion.<sup>28</sup> It was agreed that donors should be excluded if antigen or antibody were found in their blood.<sup>29</sup> It was estimated that testing for the presence of the Australia antigen and its antibody would reduce the incidence of serum hepatitis by about 25%, given the relatively insensitive nature of the tests.<sup>30</sup> The proposal for screening was implemented throughout Scotland by the end of 1971 or early 1972.<sup>31</sup>

<sup>30</sup> Ibid [SNB.002.1339] at 1343; the Bulletin of the World Health Organization, 1970, as reported in Wallace et al, 'Total screening of blood donations for Australia (hepatitis associated) antigen and its antibody', *British Medical Journal*, 11 March 1972 [SGH.002.9831]. On the relatively low sensitivity of the early Hepatitis B IEOP tests see also: Report of the Advisory Group on Testing for the Presence of Australia (hepatitis-associated) Antigen and its Antibody, 1971 [SNB.002.1339] at 1345-46; Note by Dr Macdonald, SHHD, of a meeting at the DHSS on 20 July 1970 on Hepatitis and the Australia Antigen [SGH.002.3155]; Cash, 'Principles of Effective and Safe Transfusion' *Proceedings of the Royal Society of Edinburgh*. (B) 71 (Supplement), 5, 1971/72 [PEN.002.0559] at 0566, 'While it is accepted that the CIEOP technique is basically simple it is full of pitfalls ... and liable to give false-positive and negative results. Both of these events could have serious consequences on the donor and recipient respectively'.

<sup>31</sup> Cash, 'Principles of Effective and Safe Transfusion', *Proceedings of the Royal Society of Edinburgh* (B) 71 (Supplement) 5, 1971/72 [PEN.002.0559] at 0565: Dr Cash refers to the 'recent' introduction of screening in his talk in February 1972.

**25.24** Testing to screen for the Australia antigen was introduced for all blood donations in the rest of the UK from December 1972.<sup>32</sup>

**25.25** There was, however, a degree of scepticism on the part of some Scottish scientists at this time. John Watt, Director of the Protein Fractionation Centre (PFC), and colleagues presented a paper on plasma fractionation at a Joint Symposium held by the Royal College of Physicians of Edinburgh and the Royal Society of Edinburgh in February 1972.<sup>33</sup> They discussed hepatitis transmission and the identification by Dr Baruch Blumberg and others of the 'hepatitis associated antigen' (HAA – another term for the 'Australia antigen', HBsAg). They commented:

A screening programme which results in identification of HAA carriers among blood donors, even if such identification be less than totally accurate, is bound to reduce the incidence of infection in recipients of whole blood, cellular components and whole plasma. However, it is equally certain that such screen procedures, unless they be absolutely infallible, will not greatly influence the infectivity of plasma products. This must remain the province of the fractionator and the characteristics of his technology until such time as screening systems are capable of identifying HAA presence in dilutions at least six orders of magnitude greater than can presently be detected .... Many commercial fractionators and some state organisations process pools containing as many as 30 000 donations of plasma; one unidentified infected donation would be enough to make the whole of such a pool suspect.<sup>34</sup>

**25.26** Chemical processing to inactivate pathogens, in the absence of infallible screening methodology, was identified by fractionators as the solution to virus transmission. Professor John Cash, who would become the Medical and Scientific Director of the SNBTS, referred to a range of screening techniques and commented:

This work clearly implies that the routine screening of donor blood for Australia antigen will decrease the total incidence of post-transfusion hepatitis. Although the urgency and importance of this approach cannot be overemphasised, the degree of protection offered remains uncertain, as the final analysis will be dependent upon the prevalence of antigen-positive donors in a community, which can vary widely (Prince 1970), the quality of the methods used to detect the antigen and the frequency of other potential hepatotoxic agents in the donor population.<sup>35</sup>

**25.27** Professor Cash discussed a range of clinical practices that might reduce the risk of virus transmission and commented on the tests available for the Australia antigen. He said that the recent introduction of total donor screening in Scotland was a major step forward but left much still to be done. More sensitive tests were required and there was a need for improved facilities and for a national reference laboratory for the supply of standardised reagents. He concluded:

---

<sup>34</sup> Watt et al, 'New Developments in Large-scale Plasma Fractionation', *Proceedings of the Royal Society of Edinburgh (B)* 71 (Supplement) 3, 1971/72 [PEN.002.0538] at 0551

<sup>35</sup> Cash, 'Principles of Effective and Safe Transfusion', *Proceedings of the Royal Society of Edinburgh (B)* 71 (Supplement) 5, 1971/72 [PEN.002.0559] at 0564

[W]e must not assume that the elimination of all antigen-positive units will solve the post-transfusion hepatitis dilemma. Current evidence strongly suggests that the present limitations, which have been calculated to represent a detection rate as low as 25 per cent, cannot be entirely explained on insufficient sensitivity of existing methods, and that other agents are responsible for a significant proportion of the problem.<sup>36</sup>

**25.28** In May 1972, the Maycock Group published a revised report in which it repeated its recommendation that RTCs should begin, at the earliest possible date, to test all blood donations for the presence of the Australia antigen and its antibody using, initially, an immunoelectroosmophoretic method of testing.<sup>37</sup> The report noted that knowledge of all aspects of the Australia antigen was accumulating very rapidly and that its recommendations should be regarded as interim and subject to modification at a later date.<sup>38</sup>

**25.29** Leaving aside the reservations of Scottish scientists noted at paragraph 25.25 about the effectiveness of screening in relation to large-pool plasma products, there was concern expressed in Scotland in October 1972 about the delay in introducing more sensitive screening tests for Australia antigen and its antibody.<sup>39</sup>

**25.30** The 1973 WHO report identified the tests available and commented on them.<sup>40</sup> With regard to effectiveness, it stated:

The present widely employed techniques for detecting hepatitis B antigen in blood are thought to be capable of preventing approximately 30% of cases of post-transfusion hepatitis. The effect the introduction of more sensitive techniques will have on the rate of post-transfusion hepatitis is not yet clear, but preliminary evidence suggests that it will not be great. A further significant reduction in the rate of post-transfusion hepatitis may require the development of biological tests for the hepatitis B virus, as well as a better understanding of the complex etiology of this form of the disease. Cases not due to virus B are thought to be due to a variety of causes, including hepatitis A virus, cytomegalovirus, and other, as yet unidentified agents.<sup>41</sup>

**25.31** On that assessment of the situation, the techniques then available were not very sensitive in detecting Hepatitis B and failed to detect an important proportion of cases of that type of infection, though 30% effective screening was an improvement on the Maycock Group's estimate of 25%. Further, the detection rate left unexplained other cases of post-transfusion hepatitis. As events were to prove, those included the non-A, non-B form or forms of hepatitis postulated after 1974.<sup>42</sup> Following Stephen Feinstone's identification of the Hepatitis A virus (HAV) and subsequent confirmation by 1978 that its mode of infectivity was enteral and not parenteral, HAV could be excluded as a cause of post-transfusion hepatitis. There were two remaining variables: the sensitivity of existing screening tests for Hepatitis B and the range of non-B agents capable of transmitting infection. The interaction of these variables was little understood.

<sup>42</sup> Dr McClelland – Day 9, pages 106–108

**25.32** What was increasingly understood, however, was that the problem of transfusion-associated transmission of hepatitis was more widespread than had been appreciated previously. In addition to the increasing prevalence of infection among new population groups (see paragraph 25.11 above) the report also commented:

Hepatitis B antigen has now been found in all components of plasma that are derived by the Cohn method of fractionation from plasma known to contain the antigen.... It is important to exclude antigen-positive plasma from the pool to be used for preparing blood derivatives for clinical use.<sup>43</sup>

**25.33** The risk to patients with coagulation deficiencies who required replacement therapy was recognised. There was also a need to protect transfusion patients from infected blood and blood components.

**25.34** The Maycock Group was reconvened on 6 December 1973. Its second report, dated September 1975, noted that by that date the antigen had become known as the 'Hepatitis B surface antigen' (HBsAg) and that information about the subject continued to accumulate very rapidly. During this phase of its operations, improved serological assays for HBsAg were being developed and applied routinely in the UK, including Scotland. The second report stated:

Published reports show that the incidence of hepatitis B in recipients of antibody positive [blood] is no greater than that of recipients of blood in which neither HBsAg nor anti-HBs is demonstrable. Therefore, while confirming ... that those donors whose blood is HBsAg positive should be permanently excluded from the panel and their donations rejected for clinical use, we now recommend that donors whose blood contains anti-HBs may be retained on the panel and their donations used clinically.<sup>44</sup>

**25.35** The second report of the Maycock Group was approved by the Minister of State in October 1975 and endorsed by the Standing Medical Advisory Committee (SMAC) at their meeting on 11 November 1975.<sup>45</sup> The recommendation was reflected in the advice of the National Blood Transfusion Service in 1977;<sup>46</sup> 1983;<sup>47</sup> and 1985.<sup>48</sup> The clinical use of blood containing antibodies to Hepatitis B, without detectable antigen, was now recommended.

**25.36** In the introduction to its third report, published in 1981, the Maycock Group again emphasised the rapidity with which information on the subject had been accumulating and the need to avoid regarding its recommendation as final.<sup>49</sup> It is appropriate to emphasise that there was rapid change throughout the 1970s. The deliberations and subsequent advice of the Maycock Group were based on the premise that Hepatitis B antigen-positivity remained the principal transfusion-related risk of transmission of hepatitis, although a challenge of that position was already emerging. On 3 August 1974 *The Lancet* published the important paper by Dr Alfred Prince and his colleagues which suggested that, in the USA, 'a large proportion of long-incubation post-transfusion hepatitis is unrelated to

hepatitis B and that control of post-transfusion hepatitis will require identification of a hepatitis virus(es) type C'.<sup>50</sup>

**25.37** The advice of the Maycock Group was not universally applauded. In a reply to the Group's second report, a representative of the Royal College of Physicians (RCP) commented as follows:

I do however have some misgivings about discontinuing the current practice of permanently excluding from the panel, donors with a past history of jaundice or hepatitis. Even with the most sensitive techniques false negatives may occur, and furthermore transfusion hepatitis may be caused by viruses other than Hepatitis B for which at present no tests are available (the existence of Hepatitis C was postulated recently). Although the chance that such individuals might transmit hepatitis is admittedly remote, the risk is there and not worth taking unless it can be shown that many donors are being lost to the panel in this way — what are the figures for such rejections at present[?]<sup>51</sup>

**25.38** A draft reply dated July 1976 from the DHSS to the RCP noted that the Maycock Group's recommendation agreed with a recommendation contained in the 1975 WHO Report. The draft considered the historic background of the exclusion of donors with a history of jaundice and noted the developments in the knowledge of and testing for HBsAg. It stated that no evidence had been collected yet in the UK to substantiate the presence of the postulated 'Hepatitis C' and concluded that, for these reasons, it was proposed to retain the recommendation of the Maycock Group that donors with a history of jaundice should no longer be permanently excluded from donating.<sup>52</sup>

**25.39** The DHSS distributed the second report of the Maycock Group with an accompanying circular to all regional health authorities and other bodies in England and Wales in November 1976, intimating Ministers' acceptance of the report subject to reservations and recommending implementation.<sup>53</sup> The circular drew attention to the Group's recommendation that the practice of permanently excluding donors with a history of jaundice could be discontinued, provided that HBsAg was not detected by a reversed passive haemagglutination assay (RPHA), or a test of equal sensitivity, and that the donor had not suffered from hepatitis or jaundice during the previous 12 months.

**25.40** Meantime, by about 1974 all blood donated in Scotland was screened for the presence of Hepatitis B surface antigen and anti-Hepatitis B by counter-immunoelectrophoresis (CIEP) or immunoelectro-osmophoresis (IEOP) (the 'second generation' tests).<sup>54</sup> The technology was still, in routine application, dependent on human observation. Dr Brian Dow, Glasgow and the West of Scotland BTS, explained the process as it was applied in 1974.<sup>55</sup> A sugar derived from seaweed (agarose gel) was spread on glass plates where it

<sup>54</sup> Dr Dow — Day 8, page 83. Glasgow and Edinburgh used different test methods. By the end of 1984, Edinburgh used a haemagglutination inhibition technique, see [SGF.001.2786]

<sup>55</sup> Dr Dow — Day 8, pages 84–87

formed a milky coloured surface. Test samples were added, typically in three 'wells'. Each plate comprised a reagent in one well, for example a specimen from a donor known to have Hepatitis B surface antigen-positive blood; the test sample in the middle well; and a second reagent in the third, ie a sample from a donor known to have anti-HBs. If the test sample had HBs antibody, the application of an electric current would develop a visible white line (a 'precipitin line') in the gel between the test sample and the sample with Hepatitis B surface antigen by osmosis. The same process would disclose anti-HBs, if the test sample had it, by a precipitin line in the other direction.

**25.41** The test was not very sensitive and required a far greater concentration of antigen or antibody for detection than the next generation of tests.<sup>56</sup> Dr Dow thought, however, that Glasgow had achieved a higher rate of reduction in post-transfusion hepatitis than indicated in the first Maycock Group report, achieving 30–50% success as against the 25% estimated by the report.<sup>57</sup> Success depended on observation by the technician, the quality of the reagents<sup>58</sup> and the reference laboratory back-up available.<sup>59</sup> Good technicians were required as identifying the precipitin line was a subjective exercise and technicians differed in their interpretations.<sup>60</sup> To achieve the level of success it had, Glasgow made sure that a supply of good reagents was available and had used the same reagents consistently from about 1970.<sup>61</sup>

**25.42** In England, Dr Rosemary Biggs published a report of the Haemophilia Directors' study in 1974, indicating that testing had reduced the incidence of infection in donations but also pointing to the insensitivity of the available tests.<sup>62</sup> Referring for comparison to an earlier report<sup>63</sup> from 1972 by Dr John Wallace and others, Glasgow, she wrote:

The incidence of the Hepatitis B virus in the donor population was of the order of 1 per 800 donations at the time that these observations were made. Since then the screening of all donors for Hepatitis B antigen has been instituted and the incidence of samples grossly contaminated with Hepatitis B virus is now certainly less. Screening, however, is unlikely to remove all infected samples because more than one virus is involved and because the screening method is not sufficiently sensitive to detect all samples infected with Hepatitis B virus.<sup>64</sup>

**25.43** At this time, the Glasgow and Edinburgh Blood Transfusion Services were actively engaged in research into the development and application of screening techniques and continued to develop test technology. Information on research in Edinburgh was passed to the Maycock Group following a meeting of the Central Consultative Committee on 14 October 1974.<sup>65</sup>

<sup>56</sup> Dr Dow explained that the IOEP test detected down to 1 microgram per ml of HBV surface antigen whereas current tests would get down to picogram levels: a thousand times the number of individuals with HBV surface antigen would be detected. But that did not necessarily increase the numbers detected, because most were detected by IOEP in the first place, and only a few additional individuals were picked up by RIA, the more sensitive test, when it was introduced, and later developments. <sup>65</sup> Extract from CCC minutes [SGF.001.2786]

**25.44** The second report of the Maycock Group, published in September 1975, described the principles of testing and commented that the association between the presence of HBsAg in donor blood and the occurrence of HBsAg positive hepatitis in the recipients after an incubation period of 40–180 days was established. It noted that blood and blood products could also transmit other forms of hepatitis which did not appear to be associated with the presence of HBsAg.<sup>66</sup> The results of testing by various techniques were set out and the incidence of icteric hepatitis (hepatitis, that is, accompanied by clinical jaundice) was discussed. The likely outcome of testing was noted:

Several studies in [the] USA have shown that exclusion of HBsAg positive donors diminishes the incidence of hepatitis B in transfused patients. Although comparable surveys in UK have not yet been reported, it seems likely that exclusion of HBsAg positive donors here will also be associated with a diminution in the number of cases of hepatitis B transmitted by blood and blood products.<sup>67</sup>

**25.45** The report commented that infection with Hepatitis B was associated with the appearance in the serum of a specific surface antigen, HBsAg, and its homologous antibody, anti-HBs. A second antigen-antibody system, the Hepatitis B core, appeared to be intimately related to the infection.<sup>68</sup>

**25.46** The report also noted that published information showed that the incidence of Hepatitis B in recipients of antibody-positive blood was no greater than that of recipients of blood in which neither HBsAg nor anti-HBs was demonstrable.<sup>69</sup> This led to the recommendations on donor management discussed above.<sup>70</sup>

**25.47** Notwithstanding this advice, the report stressed that a negative result for antigen and antibody, even by the most sensitive of the available methods of testing, did not necessarily imply the absence of an infective agent or agents.<sup>71</sup> Having reviewed the methods available, the Group recommended that RPHA should be adopted by RTCs in place of CIEP to screen every blood donation for the presence of HBsAg.<sup>72</sup>

**25.48** The emphasis at this stage was firmly on HBsAg identification. The confidence shown in recommending the selection of a specific method implied a step change in knowledge of Hepatitis B at about the beginning of the reference period. The history of developing scientific knowledge over the period would suggest that there was a perception that there had been significant progress, although the prevailing understanding of the virus was still incomplete. It appears that there was growing confidence in the effectiveness of the screening process to reduce, if not totally eliminate, the risk of transmission of Hepatitis B. The Maycock Group's second report noted:

In the light of the developments which have occurred since the publication of our last Report we no longer consider that CIE should be the recommended

<sup>70</sup> Ibid [SGH.003.0079] at 0090. The report also made particular recommendations relating to the use of blood and plasma donated by donors who were born or had lived in endemic malarial areas. These were related to the risk of transmission of malaria and are not relevant for present purposes.

<sup>71</sup> Second Report of the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen and its Antibody [SGH.003.0079] at 0086

<sup>72</sup> Ibid [SGH.003.0079] at 0089

technique for the routine screening by RTCs for the presence of HBsAg. The choice for a replacement method lies, in our view, between RPH and RIA .... RIA is, admittedly, more sensitive than RPH, but even so cannot be relied upon to detect HBsAg in every donation in which it is present. In our opinion the extra degree of sensitivity which RIA affords is outweighed by the considerable advantages which RPH offers in other, no less important, respects .... We therefore recommend that RPH should be adopted as soon as possible by all RTCs in place of CIE to screen every blood donation for the presence of HBsAg....<sup>73</sup>

**25.49** 'Third generation' HBsAg screening tests were introduced from 1975.<sup>74</sup> The Maycock Group noted that RPHA showed a 50% improvement in sensitivity over CIEP and approached the sensitivity of the best available test, radioimmunoassay (RIA). Dr Harvey Alter and colleagues reported on retrospective re-testing of samples previously tested by CIEP by RIA. They found that three of four patients who developed Hepatitis B infection, but were negative by CIEP, tested positive by RIA.<sup>75</sup> With the third-generation tests, from 1975, the process was increasingly automated: there was progressively less 'art' and more 'science' in testing. Tests, thought at the time to be sensitive and accurate, were beginning to be widely available for infections with Hepatitis B. Research and development continued and further improvements in the sensitivity of screening methods for HBsAg and anti-HBs continued to be made thereafter.

**25.50** Progress on consultation of the second report of the Maycock Group was reported in a memorandum by TE Dutton, DHSS, dated 16 March.<sup>76</sup> It recorded that the report was approved by the Minister of State in October 1975 and endorsed by the SMAC at their meeting on 11 November 1975, as already noted, and provided a summary of responses. Although consulted, the RTDs' responses (if any) were not summarised.<sup>77</sup> A copy of the memo was appended to a memo sent by Dr Archibald McIntyre, SHHD, on 24 March 1976, to Dr McCreadie, Dr Graham Scott and others.<sup>78</sup> It recorded that in Scotland sensitive tests for the detection of HBsAg were being used in all five RTCs.

**25.51** Until the adoption of the third-generation tests, testing for Hepatitis B was not efficient. In addition, there were no tests for hepatitis agents other than Hepatitis B. A practical assay for Hepatitis A was not available in Scotland until 1978. The inability to identify what came to be called the NANB Hepatitis viruses had, as a necessary corollary, the inability to develop any screening test or assay that would enable the exclusion of infected donations from the source materials used as whole blood, blood components or in the manufacture of blood products. (It is important to emphasise, however, that the developing knowledge that there was a form or were forms of hepatitis that did not have the characteristics of Hepatitis A or Hepatitis B logically had to mean that the most effective tests for Hepatitis A or Hepatitis B, which had to reflect the identifying characteristics of those diseases, could not detect NANB Hepatitis). Increased confidence in the sensitivity of the tests for HAV and HBV hence led to increased confidence in the existence of other 'non-A, non-B' Hepatitis virus(es). In time, a major debate would take

place over the use of 'surrogate' tests for NANB Hepatitis.<sup>79</sup> For the time being, however, there was no means of identifying any NANB Hepatitis transmissible agent in blood.

**25.52** Similar views were expressed in other countries. A study in Finland of carriers of Hepatitis B antigen and transfusion hepatitis was published in 1974.<sup>80</sup> The report stated that in most series in the literature only 40–60% of cases of post-transfusion hepatitis could be traced to a donor with HBsAg. The report listed a number of possible reasons for that, including, with reference to the paper by Prince and others in 1974 already mentioned at paragraph 25.36, that some cases of post-transfusion hepatitis might be caused by a virus not yet known.<sup>81</sup> It concluded:

The present series suggests that screening by the counter-immunoelectrophoresis [CIE] method will reduce the number of cases of transfusion hepatitis by about a third, to which the radioimmunological method [RIA] will add 10–20 per cent. It seems that the solution of the transfusion hepatitis problem demands more sensitive and more specific HBsAg testing methods that are expressly suited for routine screening, as well as methods for the demonstration of other infectious viruses in the blood.<sup>82</sup>

**25.53** In his evidence to the Inquiry, Professor Leikola of the Finnish Red Cross Blood Transfusion Service said:

[It] was realised that not all Hepatitis B cases were recognised by [the HBsAg] test, that a good part of the people that were screened were negative with the new test but were still carrying the Hepatitis B virus and [it] was known that it was a serious disease.

In addition to that, [there] was the possibility [of] other viruses existing and probable existence of other viruses.<sup>83</sup>

**25.54** In 1975, the Glasgow Blood Transfusion Centre introduced RIA testing for HBsAg and continued to use that technique until about 1977–78.<sup>84</sup> The relative effectiveness of the test was to become an issue in Scotland in and after 1976. The Maycock Group's recommendation in favour of RPHA was challenged by Glasgow transfusion experts and scientists who thought that, while the RPHA test approached the effectiveness of RIA, it ultimately fell short of it.<sup>85</sup> Dr Dow agreed that certain RIA tests developed 'in-house' (apparently a reference, for example, to the RIA favoured by the Blood Transfusion Service in England and Wales) tended to be relatively slow and tedious, taking two or three days to complete, but noted that Glasgow used a commercial test that was quick to carry out, being completed within four hours.<sup>86</sup>

**25.55** By letter to Dr McIntyre dated 22 June 1976, Dr Wallace, Glasgow & West of Scotland BTS and a member of the Maycock Group, advised that his region had continued to research the use of RIA with the cooperation and financial support of Abbott Laboratories and the agreement of General Jeffrey (National Medical Director of the SNBTS). They had

<sup>86</sup> Ibid page 116

found that the RIA test was more sensitive in detecting HBsAg positive donors than the RPHA method.<sup>87</sup>

**25.56** Dr Wallace provided evidence that the RIA test was more effective. On the basis of a study conducted to assess the sensitivity of RIA and RPHA tests it had been established that, in a nine month period using RPHA, seven HBsAg-positive donations identified by RIA had not been detected. He referred to a Fatal Accident Inquiry involving the transmission of Hepatitis B to a patient who had died and a second case where the patient had survived: each had involved false negative reactions on RPHA testing. Dr Wallace was concerned about the lack of sensitivity of the RPHA test which, he implied, might lead to further deaths if it were to continue to be used. He referred to the possibility of informing the Scottish Legal Office or his own Defence Union if a way could not be found to maintain a sensitive method of testing donations. He sought additional funding to continue screening with the Abbott RIA test after withdrawal of commercial support.<sup>88</sup>

**25.57** In a memorandum dated 28 June 1976, Dr McIntyre referred Dr Scott to Dr Wallace's letter.<sup>89</sup> He stated that Dr Wallace had been involved in the 'problems of hepatitis' right from the beginning and knew that Hepatitis B was 'only the tip of the iceberg'. In his evidence to the Inquiry, Dr Scott explained the SHHD's view: 'Well, we knew that there were other hepatitis agents involved that hadn't emerged then. Non-A non-B. Nobody had developed a test for the other forms of hepatitis'.<sup>90</sup> It is implicit in the letter that SHHD medical officials had also been aware that Hepatitis B was 'only the tip of the iceberg'.

**25.58** In other respects, Dr McIntyre expressed concern about what he perceived to be 'professional blackmail' in the letter from Dr Wallace. It seems that Dr McIntyre interpreted Dr Wallace's letter as containing a thinly-veiled threat that, if he was not given funding to continue with his study, he would report his misgivings to the professional medical and other authorities. Dr Scott replied to Dr McIntyre to the effect that the Maycock Group, of which Dr Wallace was a member, took account of the sensitivities and cost of the different tests and had recommended that testing by RPHA be introduced.<sup>91</sup> The SHHD had control of the budget and the issue was effectively disposed of on the basis of comparative cost.

**25.59** The Inquiry has been unable to recover a copy of the SHHD's response to Dr Wallace but the nature of the response is indicated in a subsequent letter dated 26 July 1976 by Dr Wallace to Chief Administrative Medical Officers in his region in which he noted:

The reply from SHHD states that RPHA is the recommended method of testing and is the method which should be employed in this region after the middle of August 1976. Accordingly, RIA testing of donations for the presence of HBsAg will cease on 14 August, 1976, and thereafter RPHA will be the method used for total screening. In the light of the evaluation it is estimated that in the course of one year from 9 to 16 donors who are chronic carriers of HBsAg detectable by RIA will not be detected by RPHA.<sup>92</sup>

<sup>91</sup> Dr McIntyre's minute to Dr Scott dated 28 June 1976 [SGF.001.2834] containing handwritten note by Dr Scott dated 29 June 1976

<sup>92</sup> Dr Wallace's letter of 26 July 1976 [SGF.001.2827]. See also Barr et al, 'HBsAg detection – results of comparative large scale testing of blood donations', *Medical Laboratory Sciences*, 1979; 36:109 [PEN.013.0393] at 0397 in which the authors compared the RPH and RIA methods of detecting HBsAg and observed that the '[f]inding of RPHA negative RIA positive HBsAg carriers therefore appears not to be a rare event. It is likely that a considerable number of such donors exist and can transmit type B hepatitis.'

**25.60** Dr Dow took up this issue in his written statement and in oral evidence.<sup>93</sup> Glasgow was, at this time, at the forefront of Hepatitis B testing.<sup>94</sup> He said that RPHA testing was a less sensitive test than Glasgow's (Abbott) RIA test. The RIA would identify a lower level of virus infectivity and, as a corollary, exclude a higher percentage of infected donations.<sup>95</sup> Dr Wallace had written to the west of Scotland haematologists because of his concerns about sensitivity, having been forced to use the less sensitive RPHA test because he was not funded for the RIA test. While RIA was in use, no confirmed cases of HBsAg post-transfusion infection were reported; after the change, four cases were reported in a year.<sup>96</sup>

**25.61** Mr Barr, Dr Dow and others wrote up the Glasgow work and published in 1979.<sup>97</sup> The paper reflected the strong views held at the time. It noted that since 1970 all blood donations in the west of Scotland had been screened for the presence of HBsAg. The method of testing in the first five years was CIEP. In that period, several cases of proven viral Hepatitis B transmission were notified, consistent with the known sensitivity of the test. In the final year of the study period, 1975–76, 8589 plasma pools were tested by a long incubation RIA method and four positive results were obtained. These four examples of HBsAg were RPHA-negative and RIA-positive and it was considered possible that was an underestimate, as factors such as neutralisation and dilution of HBsAg in the plasma pools could have influenced the number of positive results obtained. They reported that, among the three RPHA systems they had tested, there was remarkable variation in both sensitivity and specificity. The Abbott Diagnostics (Auscell) test appeared to be the most sensitive and specific, although it did fail to detect some antigen-positive donations. The British Wellcome Diagnostics (Hepatest) test was cheaper. From one year of testing using RIA, 12 of the antigen-positive donations detected by RIA failed to give a positive reaction when tested by RPHA. The conclusion was that finding RPHA-negative/RIA-positive carriers was not a rare event, an indication of the relative insensitivity of RPH assays.

**25.62** Notwithstanding the Glasgow experts' reservations, the Maycock Group's recommendations were consistent with international thinking at the time, which recognised RPHA and RIA as equally acceptable. In 1976, the International Society of Blood Transfusion published a guide to the *Hazards of Blood Transfusion*.<sup>98</sup> It stated:

Tests for HBsAg ... are now available. Although these will detect no more than about 50% of hepatitis B virus carriers, no blood or blood product should be transfused unless the donor is known to have been negative for HBsAg. It is recommended that each blood donation should be tested by such a method as counter-immunoelectrophoresis [CIE] or, preferably, radioimmunoassay (RIA) or reverse passive haemagglutination (RPHA).<sup>99</sup>

**25.63** The guide noted that the incidence of Hepatitis B was not known and was likely to vary from area to area. The report did not express a preference between RIA and RPHA: a sensitivity rate of 50% was expressed as a general feature of the available tests. Dr Wallace's preference for the Abbott RIA did not receive support from the guide. By the date of publication, with government support, the Maycock recommendations had taken effect as noted above.

<sup>99</sup> Ibid [DHF.001.2692] at 2703

**25.64** There were, however, continuing issues. There was interest in collecting data relating to all forms of adverse reaction to factor products as production increased at the PFC and concentrates became available. The clinical value of the products required reporting and study. There was a report of adverse reactions to the PFC intermediate Factor VIII, at a meeting of the SNBTS Directors on 1 July 1976.<sup>100</sup> A specific batch, batch 127, had caused reactions in Aberdeen and in Edinburgh.<sup>101</sup> Dr David Dane<sup>102</sup> had shown that the product was free of HBsAg 'at conventional test limits (and a bit beyond)'. Edinburgh and south east Scotland had found that (uniquely, according to the minute) the batch had contained no antibody to HBsAg. At a meeting of the SNBTS Directors on 4 October 1976,<sup>103</sup> the investigation of two suspect batches, including batch 127, by Dr Cash and Dr Dane, using a more sensitive test, was reported.<sup>104</sup> Batch 127 was thought to have contained one positive HBsAg donation. From the context it appears that the 'adverse reaction' reported was jaundice. It was agreed to receive information about Dr Dane's more sensitive test for examination.

**25.65** It is of interest, in assessing contemporaneous attitudes, that a question was raised at the SNBTS Directors meeting in October, apparently by Mr Watt, whether it was of real value to investigate patients who developed jaundice following the administration of Factor VIII. Mr Watt thought that it was not justified on grounds of cost effectiveness. Dr Cash and Dr Charles Cameron, East of Scotland BTS, prevailed: investigation would continue. It was thought that Edinburgh in particular had benefited by changing their technology to meet the situation that had arisen from the investigation of batch 127. More generally, the episode is an indication that the differences of opinion between fractionators and clinicians that had been expressed in the early 1970s had not been resolved.

**25.66** In his book *Blood Transfusion for Clinicians* (1977), Dr Wallace observed:

The recognition of HBsAg as a marker for the infective agent of type B hepatitis introduced the possibility of testing every blood donation for the presence of HBsAg. Considerable discussion ensued as to the benefits resulting from the costly, and time-consuming procedure of total screening. Some authorities stated that the exclusion of HBsAg positive donors would at best reduce the incidence of post-transfusion hepatitis by only 25 per cent. The inability to prevent 75 per cent of cases of transfusion-transmitted hepatitis was considered to be multifactorial:

- i. the methods of detecting HBsAg by large scale screening were the relatively insensitive immunodiffusion (ID) and counterimmunoelectrophoresis (CIEP) techniques.
- ii. it was suspected that HBsAg was not homogeneous, and that different subtypes would make detection difficult.
- iii. other infective agents might transmit hepatitis: these included virus A, CMV, EBV and viruses not yet identified, such as the predicted virus C.
- iv. the use of absolutely fresh untested donations: some clinicians considered that fresh blood had clinical merit and insisted on its use.

<sup>101</sup> Ibid [SGF.001.0282] at 0285

<sup>102</sup> A member of the Maycock Group, Dr Dane led the team of scientists who, in 1970, discovered the complete Hepatitis B virus.

<sup>103</sup> Minutes of SNBTS Directors Meeting, 4 October 1976 [SGH.001.1320]

<sup>104</sup> Ibid [SGH.001.1320] at 1321. (The reference to 'batch 124' in the header to this paragraph appears to be a typographical error).

- v. a route of transmission other than transfusion: it was recognized that various hepatitis viruses could be transmitted by parenteral routes other than transfusion and by close contact.

The prevention of even 25 per cent of cases of post-transfusion hepatitis was however regarded as statistically impressive.<sup>105</sup>

**25.67** Dr Wallace referred to the work of Dr Prince and others in the USA that concluded that an infective agent other than Hepatitis B was involved in causing post-transfusion hepatitis.<sup>106</sup> He wrote:

Evidence from the USA indicates that a long incubation form of hepatitis other than type B exists, and this has been named type C or 'non-A non-B'. Present evidence on this infection in Britain is scanty, but most cases of post-transfusion hepatitis seem to be type B, although some cases with relatively short incubation periods are associated with type A or CMV or EBV infections. It may be that at present type C infection is rare in Britain. More evidence on this subject will emerge as RPHA and RIA are introduced as the method of testing donations for HBsAg.

....

While type B hepatitis seems to be the form of post-transfusion hepatitis most commonly encountered in Britain, it would be advantageous to recognize markers for the infective agents of 'non-B' hepatitis, such as type A and type C, if the latter really exists.<sup>107</sup>

**25.68** The book was written in 1976 and published in 1977. It reflected Dr Wallace's views at a time when he would clearly have thought that the choice between RIA and RPHA was open for discussion by the Maycock Group and when the prospects for both test formats seemed promising. In addition, the text must have been written shortly before it became clear that Hepatitis A was not a material cause of post-transfusion hepatitis.

**25.69** Commenting on the position at 1977, the date of publication, Dr McClelland, who became a consultant in the Edinburgh and South East of Scotland Blood Transfusion Service in 1977 and Director in 1979, was less sanguine.<sup>108</sup> In his written evidence,<sup>109</sup> he pointed to two apparent underlying assumptions: (i) that testing donations with a very sensitive test for HBsAg and removing all donations with positive test results would virtually exclude the risk of transfusion-transmitted Hepatitis B and (ii) that, provided Hepatitis B transmission was avoided, the blood would be safe. He commented that this seemed somewhat at odds with the statements that referred to 'other infective agents that might transmit hepatitis, such as the predicted virus C' and with the fact that Hepatitis B screening was thought to detect only 25% of cases of post-transfusion hepatitis. In his written statement, Dr McClelland said:

I think this apparent inconsistency must be a reflection of the prevailing sense at the time that hepatitis, if not due to Hepatitis B virus, was not a serious condition.<sup>110</sup>

<sup>110</sup> Ibid [WIT.003.0072] at 0079

**25.70** He expanded on these matters in oral evidence. He was asked whether, at the time of publication of Dr Wallace's book, he would have shared that 'prevailing sense'. He replied:

I have found this very confusing when I read it again because it seemed to be saying several conflicting things. I would not have shared that view. I do think that, lying in back of this is something which I think came through to me in reading a lot of this material again, that there was a very strong sense within the UK that non-A non-B hepatitis wasn't a big problem in the UK.

There was clearly awareness that it was a big problem in the United States, that is in spite of the fact that the only prospective study of transfusion-transmitted hepatitis that was done for many years was organised by the Medical Research Council in the UK and published in 1974. The data, [were] actually interpreted as saying that it wasn't a problem apart from Hepatitis B. Non-A non-B hepatitis wasn't a problem but actually, if you look at the data for five minutes, it actually clearly is a problem and that, you know, coming from a group of eminent academics seems – again, I had real difficulty understanding that when I looked at it again.

It does seem to me that there must have been a very strong received belief that somehow non-A non-B hepatitis just wasn't a problem in the UK sufficient to cause highly intelligent people doing research study to actually really ignore their own findings and interpret them quite inappropriately, in my view. So I think that sort of attitude, the power of that sort of attitude must underlie this statement of Dr Wallace. It's speculation.<sup>111</sup>

**25.71** It would seem reasonable to assume that Dr Wallace's book reflected accepted knowledge among senior practitioners in Scotland, and among experts throughout the UK, at the beginning of Dr McClelland's career in transfusion medicine. As already noted, Dr Wallace was a member of the Maycock Group. On the other hand, Dr McClelland's interest in transfusion-transmitted viruses was engaged by US research, including the report of the Transfusion-Transmitted Viruses Study and the work of Dr Jay Hoofnagle and others.<sup>112</sup> For him, the view that somehow NANB Hepatitis was not a big problem in the UK was inconsistent with the knowledge that only 25% of cases of post-transfusion hepatitis could be explained by Hepatitis B and that other (known) causes including Epstein-Barr virus were not significant. In his view, the data could be interpreted as indicating NANB Hepatitis was quite a large problem: there was quite strong evidence that something was going on.

**25.72** A similar view to Dr McClelland's was taken in Finland. In his evidence to the Inquiry, Professor Leikola was asked about his understanding of NANB Hepatitis in the mid-to-late 1970s and replied:

Well, I would say that after summer 1978, when I came back from my sabbatical year in America, when I was not involved in these cases at all – but after that I think that it became clear in our minds that there is definitely a virus, or maybe maximum two viruses, causing hepatitis that is like Hepatitis B and unlike Hepatitis A.

---

<sup>111</sup> Day 9, pages 44–45

<sup>112</sup> Ibid page 55

However, in those circumstances we also were feeling that, yes, it may cause a disease. It is mentioned in this article<sup>113</sup> that in most cases the disease is mild and non-symptomatic and there were very little means to avoid [it] because we did not know any particular risk groups, even though it's clearly referred in this article that in most cases it is related to some parenteral contact with blood, either by tattooing, needle sharing or transfusion. But, yes, I would say that at that time, 1978, 1979, 1980 it became clear to us that such a disease exists.<sup>114</sup>

**25.73** The views of Dr McClelland and Professor Leikola reflected the influence of developing thought in the USA, where it was recognised that there was a significant prevalence of NANB Hepatitis. At this stage there were few reported NANB Hepatitis cases in Scotland.

**25.74** In relation to reported cases, Dr Dow said that, although he was aware of reports elsewhere in the world, he was not aware of NANB Hepatitis in Scotland until 1979 when Dr Follett, the Head of the Hepatitis Reference Laboratory, raised the issue with Dr Ruthven Mitchell, Director of the Glasgow and West of Scotland BTS.<sup>115</sup> In 1979, Dr Follett had a reliable test for Hepatitis A which had become available during 1978 (five years after Feinstein and others reported the isolation of the Hepatitis A virus) and could differentiate acute cases of Hepatitis A and B, allowing for effective screening for both viruses. The balance – outstanding cases of post-transfusion hepatitis – became potential non-A non-B cases. He had identified a few cases of post-transfusion hepatitis which, following testing, were found to be definitely neither Hepatitis B nor Hepatitis A. Again this evidence pointed to a material change of position shortly after the date of Dr Wallace's book, coinciding in time with Dr McClelland's appointment as consultant. It appears that the risk of transmission of NANB Hepatitis, previously recognised in theory, was becoming acknowledged as an existing risk in Scotland by the end of the 1970s.

**25.75** On 5 May 1979 *The Lancet* published a paper by Robert Galbraith and colleagues on an outbreak of HBsAg-negative hepatitis in a renal unit at Fulham Hospital, London, in 1968–70.<sup>116</sup> The paper explained that to clarify the aetiology of the outbreak serological tests for antibody to HAV were carried out retrospectively on serum samples obtained at the time of the outbreak.<sup>117</sup> The authors concluded:

Overall these results must indicate that the development of chronic liver disease was not related to hepatitis A infection and that this outbreak falls into the category of [NANB] hepatitis. More and more data point to this as the cause of a substantial proportion of cases of post-transfusion hepatitis negative for HBsAg and to its role in the subsequent development of chronic liver disease.<sup>118</sup>

C.f. an earlier report of the same outbreak, which made no mention of the possibility that the outbreak may have been caused by NANB hepatitis: Galbraith et al, 'Chronic liver disease developing after outbreak of HBsAg-negative hepatitis in haemodialysis unit', *The Lancet*, 8 November 1975; 886 [PEN.013.1426]. In his evidence to the Inquiry, Professor Cash spoke of a fatal outbreak of hepatitis at the renal dialysis unit in Edinburgh in 1969–70 having, once Hepatitis C tests became available, been shown to have been caused by both Hepatitis B and Hepatitis C: Day 10, pages 102–103

<sup>117</sup> In his evidence to the Inquiry, Dr Dow explained that although the Hepatitis A virus had been identified in 1973, it was not until about 1978 that reliable tests for Hepatitis A became available: Day 8, pages 130–131

<sup>118</sup> Galbraith et al, 'Non-A non-B hepatitis associated with chronic liver disease in a haemodialysis unit', *The Lancet*, 5 May 1979; 951 [LIT.001.0395] at 0397

**25.76** In August 1979 Dr Ajay Chaudhuri and others reported on patients thought to have viral hepatitis admitted to the Infectious Diseases Units at Ruchill and Belvedere Hospitals, Glasgow, in 1976 and 1977.<sup>119</sup> During that two-year period, 164 patients with viral hepatitis were admitted to these hospitals. Of these patients, 52 were positive for Hepatitis B antigen, with males still greatly outnumbering females and with most cases in the 16–29 year age group. The authors noted: 'As in previous years, drug abuse was associated with the largest number of cases, with 22 patients admitting use of intravenous narcotic drugs with shared syringes and needles. They were mostly men (19 male: 3 female) in their twenties'. In the 112 patients who were HBsAg-negative, a diagnosis of non-B hepatitis was made with, in the majority of these patients, epidemiological findings and clinical course suggesting a diagnosis of Hepatitis A.

**25.77** In a discussion of non-A, non-B Hepatitis the authors noted:

In four patients with non-B hepatitis, hepatitis developed within 2-6 months of transfusion of blood products. Three male haemophiliacs and a female patient with Christmas disease had received numerous transfusions of factor VIII and cryoprecipitate. These four patients and also two drug addicts with hepatitis had no evidence of hepatitis B infection, nor of hepatitis A infection nor of infection with cytomegalovirus, nor EB virus. At present they are classified as cases of [NANB] hepatitis. Evidence from other countries suggests that a virus (or viruses) may be associated with this type of hepatitis and that a carrier state is possible. With laboratory tests now permitting definitive diagnosis of hepatitis A virus infection, as well as hepatitis B, in 1979 it should be possible to determine the prevalence of [NANB] hepatitis in the general population in West Scotland.<sup>120</sup>

**25.78** It appears, therefore, that there was an attitude in the UK among some experts that persisted into 1979, that NANB Hepatitis, particularly following blood transfusion, was common in the USA but that it had not become a major problem in the UK generally and in Scotland in particular. This attitude was to find an echo five or six years later in early responses to the arrival of HIV/AIDS in the USA. Attitudes were, however, changing by the end of the decade, under the influence of US research. Dr McClelland and the west of Scotland experts were taking a fresh look at the issue and research in this country picked up pace.

**25.79** In 1978 Dr Rosemary Biggs, the Director of the Oxford Haemophilia Centre, published the second edition of her textbook, *The Treatment of Haemophilia A and B and von Willebrand's Disease*. One of the four complications that was said to arise from treatment with plasma fractions was the transmission of an infective organism, in particular hepatitis, to the patient.<sup>121</sup> Dr Biggs identified infective hepatitis, virus A and virus B, as transmissible agents, distinguishing them in the first place by their respective incubation periods and secondly discussing modes of transmission. The text proceeded:

Donor testing is important but at present no testing procedure will eliminate all samples infected with hepatitis B virus. The very high incidence of HBsAg in the blood of commercial donors means that even when the known positive

<sup>119</sup> Chaudhuri et al, 'Viral hepatitis in Glasgow 1976-1977', *CDS 79/8*, viii [PEN.002.0511]

<sup>120</sup> Ibid [PEN.002.0511] at 0513

<sup>121</sup> Biggs, R. *The Treatment of Haemophilia A and B and von Willebrand's Disease*, 1978, Blackwell Scientific Publications, Oxford, page 181

samples are excluded, the blood products made from commercial donor blood are liable to be more infective than similar products made from volunteer donor blood.

A rather high proportion of haemophilic patients who develop hepatitis have no serological evidence of hepatitis B virus infection. These patients may have hepatitis A for which no serological tests are at present available. They may also have long incubation type hepatitis the causative agents for which have as yet not been identified. They may even develop jaundice for other reasons, for example haemolytic response to the infusion of blood group antibodies.<sup>122</sup>

**25.80** The book was probably written in 1977, when Dr Biggs may not have been aware of research in the west of Scotland. It would be 1978 before Dr Follett, for example, had a reliable test for Hepatitis A. Dr Biggs' book recognised, however, that the 'long incubation type' hepatitis might have infected the haemophilia community.

**25.81** Work on identifying the extent of NANB Hepatitis in the west of Scotland, begun in the late 1970s, was continued by Dr Dow, Dr Follet, Dr Mitchell and Professor Norman Grist (University of Glasgow) with grant support from the Scottish Hospital Endowments Research Trust.<sup>123</sup> However, a full prospective study would have been wide-ranging and expensive and was not undertaken.<sup>124</sup> Throughout 1980–1985, Dr Dow carried out ALT<sup>125</sup> testing on a sporadic basis, using prison sessions. Prison sessions were an obvious target as prisoners had already been shown to have a high incidence of Hepatitis B and NANB Hepatitis was also thought to be blood-borne. People with haemophilia, intravenous drug users and renal dialysis patients were also obvious populations.<sup>126</sup>

**25.82** Thus, while established UK transfusion experts (including those practising in Scotland) were sceptical, at this stage, of the frequency of one or more non-B blood borne-viruses, some transfusion doctors and haemophilia doctors were implicitly acknowledging that such viruses were probably by no means rare, even if their apparent pathological importance had yet to be appreciated.

**25.83** It was suggested in Dr Biggs' book that mildly affected haemophilia patients who had never or rarely been transfused should not receive large-pool commercial concentrates. Rather, Dr Biggs suggested, they should be given cryoprecipitate or small-pool concentrates. Dr Biggs concluded, however, that treatment with concentrates should not be withheld from severely affected patients because of the danger of hepatitis since 'the danger of death from haemorrhage and crippling' was of 'more immediate importance'.<sup>127</sup> (There was no mention of NANB Hepatitis in the book, apart from what might be inferred from the passage quoted.)

**25.84** It seems likely that Dr Biggs' book, which was presented as 'an authoritative and up-to-date guide for haematologists, physicians and surgeons who care for haemophilia patients', would have had a wide circulation among clinicians, as would Dr Wallace's book of the year before. Dr McClelland's retrospective review of Dr Wallace's book left him

<sup>122</sup> Ibid page 181

<sup>125</sup> Dr Dow's research refers to SGPT, serum glutamic-pyruvic transaminase, another term for alanine transaminase, ALT.

<sup>126</sup> Dr Dow – Day 8, pages 149–150

<sup>127</sup> Biggs, R. *The Treatment of Haemophilia A and B and von Willebrand's Disease*, 1978, Blackwell Scientific Publications, Oxford, pages 186–187

confused. In the case of Dr Biggs' book, the lack of comment on the work of Feinstone and others on testing for Hepatitis A from 1973 onwards,<sup>128</sup> or on the application of the test reported by Alter and others in *The Lancet* in 1975,<sup>129</sup> might similarly be questioned. On the other hand, it is likely that, typically, textbooks for practitioners report generally accepted science, and it is right to bear in mind that there can be a significant gap between the level of understanding and what can be gleaned in retrospect from a wide reading of specialised professional literature.

**25.85** On 20 August 1978 the Haemophilia Centre Directors' Hepatitis Working Party, chaired by Dr Craske, produced a report which discussed the pilot project initiated by Dr Craske to investigate the incidence of chronic liver disease in patients treated with Hemofil (a brand of commercially produced Factor VIII) in 1974–75.<sup>130</sup> Under the heading 'Prevention of Virus Infections', the report expressed doubts about screening tests for HBsAg:

#### Screening tests for HBsAg

Further studies have been carried out over the past year with batches of factor VIII suspected of having been contaminated with hepatitis B virus .... Since 1975, all batches of concentrate known to be associated with cases of acute hepatitis B have been negative for HBsAg by radioimmunoassay. However, despite improved donor screening in the USA, cases of overt hepatitis B still occur associated with every brand of large pool factor VIII, including NHS factor VIII.

It is evident, therefore, that screening tests for HBsAg are not sensitive enough to detect all donor plasma infected with hepatitis B virus, even when the concentrate is prepared from donations of plasma from volunteer donors.

....

Efforts are being made to increase the sensitivity of screening tests, but it seems unlikely that this will significantly reduce the incidence of hepatitis B from the present level.<sup>131</sup>

**25.86** By 1979, therefore, the position in Scotland can be summarised as follows:

- It was known that the best available screening tests for Hepatitis B still failed to detect a significant minority of Hepatitis B-infected donations.
- It was known that NANB Hepatitis had been found in the Scottish population by the exclusion of Hepatitis A and B by Dr Follett and his group using tests covering both infections which were available from 1978.
- There was still no screening test for NANB Hepatitis infection.
- The prevalence of NANB Hepatitis infection was not known.
- There was a clear need for further relevant research.

<sup>128</sup> Ibid. Book jacket.

<sup>129</sup> Alter et al, 'Clinical and serological analysis of transfusion-associated hepatitis', *The Lancet*, 1 November 1975; 838–841 [LIT.001.3926]

<sup>130</sup> Report of the Haemophilia Centre Directors' Hepatitis Working Party – 1978 [SNB.001.7192]

<sup>131</sup> Ibid [SNB.001.7192] at 7197–98

**25.87** The detection rate on screening for Hepatitis B was probably over 80%, and the risk of transfusion-transmitted Hepatitis B was reduced accordingly. However, for large-pool concentrates screening was virtually ineffective having regard to the likelihood of the pool containing infected donations that had escaped detection on screening.

### The early 1980s

**25.88** There was official recognition of the need for further research early in 1980. An undated internal DHSS note, probably circulated in early 1980, commented on the reasons for a proposal to set up an Advisory Group on Viral Hepatitis. The purpose of this group was to advise on the public health aspects of hepatitis.<sup>132</sup> The context, reflecting knowledge of hepatitis infection among officials, is, however, relevant. The introduction to the note narrated that three and possibly more agents were known to cause viral hepatitis, with differences in their mode of spread and other epidemiological features. Increased knowledge had led to an even greater awareness of the problems which were arising. The note stated: 'At present hepatitis B presents the majority of problems and is responsible for the majority of enquiries but [NANB] hepatitis is already becoming a major source of concern'.<sup>133</sup>

**25.89** The terms of reference proposed for the new Advisory Group were to advise the Chief Medical Officers (CMOs) of the Health Departments of the UK on all aspects of communicable hepatitis. The most important problems anticipated were related to: health and safety for NHS staff in direct contact with individuals who were carriers of Hepatitis B antigens; risks to patients from NHS staff; prevention and control of hepatitis; hazards associated with equipment; and hazards associated with blood and blood products in particular. It marked the beginning of a new phase in official recognition that there were public health issues relating to transmission of hepatitis. It is significant, however, that Hepatitis B was still identified among the most important problems. NANB Hepatitis was noted as becoming a cause for concern but was not included in the list of the most important problems in the field.

**25.90** As appears from the discussion in Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*, other groups among the several that became active in the early 1980s were more relevant for present purposes, although provision was made for cross-representation of membership and the sharing of minutes of meetings.<sup>134</sup> The evidence indicates that a more structured approach was taken by the Health Departments to obtaining advice from this stage on.

**25.91** In 1981 the Maycock Group published its third report.<sup>135</sup> While the report mainly dealt with testing for Hepatitis B, it also noted:

[NANB] hepatitis viruses are a common cause of [post-transfusion hepatitis] in the United States and are thought to have been responsible for cases of [post-transfusion hepatitis] in the UK. Hepatitis due to these viruses is common among haemophiliacs and follows the administration of imported, and occasionally of British Factor VIII and Factor IX. There is evidence for the occurrence of sporadic

<sup>132</sup> See Minutes of the MRC Working Party on Post-Transfusion Hepatitis of 14 February 1980 which anticipated the early formation of the DHSS Advisory Group [PEN.017.1710]

<sup>133</sup> DHSS note 'Advisory Group on Hepatitis' [DHF.002.9099]

<sup>134</sup> For example with the UK Working Party on Transfusion-Associated Hepatitis [PEN.017.1716]

<sup>135</sup> Third Report of the Advisory Group on Testing for the Presence of Hepatitis B Surface Antigen and its Antibody: 1981 [DHF.003.0037]

cases of [NANB] hepatitis in the general adult population and in association with cryoprecipitate therapy in the UK.

There are at the present time no screening tests for detecting [NANB] hepatitis viruses in blood donations.<sup>136</sup>

**25.92** In oral evidence relating to donations collected in European penal institutions in the period 1975–83, Professor Leikola commented that he believed that many Europeans thought at the time that the problem of intravenous drug use in prisons was much smaller as compared to the problem in US institutions.<sup>137</sup> He went on to comment more generally:

Most of the research on Hepatitis B was done in the United States. Therefore I think that the investigators were readily willing to accept that the denial of using intravenous drugs was true. Secondly, in the 1970s it was well established that the occurrence of hepatitis virus was more common in prisoners as compared to the population at large. Wallace et al, 1972, assumed that the high incidence may be related to social habits and hygiene. This assumption was more or less copied to the later report by Barr and others in 1981. At the time when Wallace et al wrote their report, probably 1971, knowledge on the routes of infection was not as clear as it was later. Hepatitis A virus in contrast to Hepatitis B virus is water-borne and an infection could be related to poor hygiene. Other more realistic thoughts about the aetiology of Hepatitis B were expressed by Dr Helske in 1973.<sup>138</sup>

## Discussion and Comment

**25.93** Testing blood donations for infection at the beginning of the reference period was still relatively rudimentary and was necessarily related to contemporaneous knowledge of the risks of transmitting disease by use of human blood, blood components and blood products. Developing knowledge of these risks is a major topic for this Inquiry and is dealt with, in relation to hepatitis, in Chapters 14–16, *Knowledge of Viral Hepatitis 1 to 3*.<sup>139</sup>

**25.94** There is a degree of artificiality in separating out topics such as the developing knowledge of the risk of transmitting disease, particularly hepatitis, donor selection, technological change and even manufacturing capacity. Similarly, a strict chronological account of events would fail to capture the atmosphere of medical and scientific research and development at the beginning of the reference period. Reference to the events of the preceding decade in particular, and some earlier events, has been required. In particular, setting out the evidence on a simple chronological basis would not present a satisfactory historical perspective, therefore a more analytical approach has been adopted. Chapter 18, *Collection of Blood – General* will deal with collection procedures generally and in particular the exclusion of individuals with a history of hepatitis or of transfusion. In this chapter, the emphasis is on the relevance of the early assays for infection with hepatitis viruses to donor exclusion policies.

<sup>139</sup> See also Chapters 23 and 24 on viral inactivation of blood products; Chapter 25 on screening donated blood for HBV; Chapter 27 on surrogate testing for NANB Hepatitis; and Chapter 31 on screening for HCV.

**25.95** The difference of opinion illustrated by the controversy over the adoption of RPHA technology in preference to RIA set out in paragraphs 25.54–25.56 demonstrates that there was active research into the best available methods and that two groups of scientists took different views at the time. In Dr Wallace's view, the less sensitive test was selected but the Maycock Group's recommendation for that test was supported by relevant expert opinion, in the UK and internationally, and cannot be criticised as inappropriate. Of course, the emphasis was on Hepatitis B at a time when there was evidence suggesting that NANB Hepatitis was a threat that was not addressed by either test.

**25.96** It is clear that until the early to mid-1970s there was a strand of belief that, once screening for Hepatitis B had been dealt with, the problem of post-transfusion hepatitis would have been solved.<sup>140</sup> It was thought, correctly as events were to show, that there is no chronic carrier state for Hepatitis A infection which, in any case, is almost never transmitted by transfusion. Until 1973 or 1974 (depending on whether one has regard to the most advanced research) only Hepatitis B was relevant to transmission. The methods of detection of Hepatitis B until then were, however, inefficient. Two factors emerged in the mid-1970s. First, it was realised that the assays available were not able to detect all cases of Hepatitis B infection due to a significant problem of false negatives. Secondly, it was generally agreed that not all cases of post-transfusion hepatitis were caused by Hepatitis B type infection and that, as more Hepatitis B carriers were eliminated from serving as blood donors, the proportion of cases due to other types of hepatitis would increase.<sup>141</sup>

**25.97** The original rationale for the exclusion from donation of individuals with a clinical history of hepatitis was based on evidence that some of them remained infectious long after the apparent resolution of their illness. It was thought that most were Hepatitis B patients. That was correct up to a point: most haemophilia patients in the 1960s and 1970s had been infected with Hepatitis B. It may have been an acceptable view more generally so long as only the Hepatitis A and Hepatitis B viruses were believed to exist. Once it was realised that more efficient tests were throwing up an increasing proportion of cases that were not Hepatitis B or Hepatitis A, however, there was a problem, obvious with the benefit of hindsight at least. When two potential causes of disease were increased to three, there could be no logical basis for a view that all cases of continuing illness were associated with the first two identified, and with them alone, to the exclusion of the newly postulated virus. It was never suggested that NANB Hepatitis was a 'new' virus in the sense of a virus affecting humans for the first time (as was to be suggested in the case of HIV); rather, it was an undiscovered virus of undetermined epidemiology. The early HBsAg assays identified 25–30% of 'hepatitis' cases as associated with Hepatitis B. That left a very large balance of cases that might have been associated with Hepatitis A, Hepatitis B or NANB Hepatitis: they were all cases of 'hepatitis', generally defined. In the light of later scientific developments, and perhaps even in the light of contemporaneous US literature, Dr McClelland's concerns about Dr Wallace's views were well founded. After 1979, with more sensitive tests for Hepatitis B and routine testing for Hepatitis A becoming available, the identification and definition of NANB Hepatitis cases among all cases of hepatitis would become much more clear cut.

<sup>140</sup> Dr McClelland – Day 9, pages 106–107

<sup>141</sup> 'Viral Hepatitis: Report of a WHO Scientific Group', *World Health Organization Technical Report, Series 1979*, No. 512 [SGH.002.9746] at 9754 and 9762

**25.98** The natural history of NANB Hepatitis was assumed to be mild, or benign, until biopsy evidence began to change perceptions of its seriousness. It can now be seen that the assumption was wrong. The facts, however, are clear: for a significant period after the discovery that there had to be one or more viruses causing hepatitis that was neither type A nor type B, many experts thought that NANB Hepatitis was a mild or benign condition. The confusion and complexity arising from co-infection by both Hepatitis B and NANB Hepatitis, mentioned at the outset of this chapter, in many cases 'cloaked' any NANB Hepatitis infection for a period. Hepatitis B causing more overt clinical illness allied with the relatively un-symptomatic nature of NANB Hepatitis infection in most cases provides at least part of the answer to the problem.

**25.99** So far as positive identification of NANB Hepatitis viruses is concerned, the technology had not been developed: it was not developed until the very end of the 1980s. There was nothing that could have been done to identify the virus or viruses. In time, the dangers presented by NANB Hepatitis infection were recognised. As indicated in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*, Patrick Mollison's textbook on blood transfusion medicine indicated a view in 1983 (the end of the current period of discussion) that NANB Hepatitis was as a rule symptomatically mild, though a majority of patients had abnormal liver enzyme results and 10% of liver biopsies showed evidence of cirrhosis. Knowledge of the risk was beginning to emerge. Whether anything could have been done to reduce risk, while making available therapeutic materials for treatment of coagulation defects, blood and blood components for transfusion, short of the development of an effective assay, is discussed in Chapter 27, *Surrogate Testing of Donated Blood for non-A, non-B Hepatitis*.

**25.100** The proposal to set up an Advisory Group on Viral Hepatitis, together with the Maycock Group and the MRC and BTS initiatives (discussed in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*) indicate a more structured approach by the Health Departments and National Health Service agencies to obtaining advice on hepatitis generally from the early 1980s onwards. The developments are best understood in the context of specific topics. In general, however, it is clear that the early years of the 1980s marked a change in the appreciation of the nature of the risks of transmission of viral hepatitis. Hepatitis B remained a significant problem. The importance of NANB Hepatitis was beginning to be appreciated.

## Conclusions

**25.101** In about 1983, on the eve of the AIDS epidemic as it was to develop in the UK, Hepatitis B was known to be a disease with potentially serious outcomes for patients. It was known that HAV was almost never transmitted by blood, while HBV was not the only hepatitis virus that presented risk of transfusion-transmitted hepatic disease. However:

- Screening tests for Hepatitis B remained imperfect and were still believed to fail to identify a significant minority of Hepatitis B infected donations.
- Samples testing negative for Hepatitis B (and, where tested for Hepatitis A, also negative for that infection) necessarily still included an unknown proportion that were infected with Hepatitis B and an unknown proportion that were infected with NANB Hepatitis or both.
- The exact proportion of donations infected with NANB Hepatitis could not be determined by exclusion using existing screening tests for Hepatitis A and Hepatitis B.

- There was no serological or other screening test for the NANB Hepatitis agent of transmission.
- Knowledge of the prevalence of NANB Hepatitis in the UK, including Scotland, was at a very early stage of development.
- Because of the emphasis on clinical symptoms and overt jaundice as indications of viral hepatitis, NANB Hepatitis was thought to be rare in Scotland.
- NANB Hepatitis was generally thought to have a benign prognosis.
- The risks for the patient that might be associated with the transmission of NANB Hepatitis were thought to be low relative to the risks associated with the conditions for which they required blood transfusion in surgery or in medical treatment of their primary conditions.

## CHAPTER 26

### DONOR SELECTION – HIGHER RISK DONORS

#### Introduction

**26.1** This chapter sets out donor selection policies and practice in the 1970s and early 1980s relating to the acceptance of blood from particular groups of donors who, either at the time or with the benefit of hindsight, might be considered to present a higher risk of transmitting hepatitis viruses than the general population. The main groups under discussion in the chapter are intravenous drug users and prisoners. Military personnel from the USA are also discussed.

#### Intravenous drug use

**26.2** Intravenous drug users (IVDUs) presenting at ordinary SNBTS public sessions as prospective donors would be received, interviewed and observed as would any other member of the general public. The prospects of their identification as IVDUs would be related to general practice at interview and observation of the prospective donor, as discussed in Chapter 18, *Collection of Blood – General*. In relation to prospective donors who used or were suspected of using intravenous drugs, particular questions arise in the case of those detained in penal institutions. That topic is discussed later in this chapter.

**26.3** It was a feature of the evidence about donor selection from the earliest years of the reference period that a recent or current history of injecting drugs, or physical evidence of having injected drugs, was seen as a ground for exclusion. Whether the prospective donor would have been asked about drug use was a different matter, however. As noted in Chapter 18, *Collection of Blood – General*, there was relatively little face-to-face questioning of donors presenting at sessions. Intravenous drug use was not necessarily one of the features drawn to the prospective donor's attention as affecting their suitability as a donor. Dr Brian McClelland, who joined the Edinburgh and South East of Scotland Blood Transfusion Service (BTS) as a Consultant in 1977 and became Regional Director in 1979, thought that the majority of staff would have asked about drugs, but he could not be sure that it happened in the period before routine questioning of the donor was instituted in his area in 1982 or 1983.<sup>1</sup>

**26.4** A new comprehensive guide was prepared at that time, in response to the observations of the Medicines Inspectorate, for use in the Edinburgh and South East of Scotland BTS. The copy of the guide recovered by the Inquiry is only partly legible. In relation to drug use, however, the guide advised SNBTS staff to consult the doctor or sister on duty. As general guidance, it stated:

At least 6 months should elapse after the use of parenteral drugs because of the risk of serum-hepatitis.

Donors under the influence of oral drugs should not be accepted.

In both cases, bear in mind the possibility that the history given by these donors regarding the abuse of drugs may be unreliable.<sup>2</sup>

---

<sup>1</sup> Chapter 18, *Collection of Blood – General*

<sup>2</sup> SEBTS Response to Medicines Inspectorate [SGH.003.5059] at 5101

**26.5** Temporary deferment of IVDUs appears to reflect a view that a six-month deferment period was sufficient for Hepatitis B to have become detectable on screening. On the copy available to the Inquiry is a manuscript note: ‘International policy’.<sup>3</sup> Such a policy, however, would not have excluded donors who had become infected with non-A, non-B Hepatitis (NANB Hepatitis) as a result of injecting drug use.

**26.6** So far as Glasgow and the west of Scotland was concerned, the evidence of Mrs Rosalind Prior, who was employed by the SNBTS as a Mobile Team Assistant in the region between 1969 and March 1974, was that in the early 1970s staff were never told to ask any donors if they had ever used intravenous drugs.<sup>4</sup> Dr Ruthven Mitchell, Director of the Glasgow and the West of Scotland BTS from 1978 to 1995, stated that:

Throughout the life of the UK transfusion services, it was always thought that donors were selected on the basis of ‘tinker, tailor, soldier, sailor, rich man, poor man, beggar man, thief’, great efforts are made to avoid any discrimination.<sup>5</sup>

**26.7** He was, however, quite clear that known drug addicts were not to be bled as donors.<sup>6</sup>

**26.8** In international guidance, an association between intravenous drug use and transmission of Hepatitis B was noted before the beginning of the reference period. The 1971 World Health Organization (WHO) *Guide to the Formation and Operation of a Transfusion Service*<sup>7</sup> stated that, during the physical examination of the blood donor, ‘the medical officer should be able to pick out those prospective donors who may be, for example ... drug addicts’.<sup>8</sup> Dr McClelland’s evidence was that the interview routine was supplemented by observation.<sup>9</sup> A matter of interest for SNBTS staff would be whether, when the donor’s arm was exposed to take a sample, evidence of needle injection tracks might be disclosed. It is not clear to what extent a ‘physical examination’ was carried out in the first half of the 1970s, however. Mrs Prior’s account of the procedure in her area does not mention what the doctor in attendance at donor sessions did routinely.

**26.9** Relying on such observation as was possible in those circumstances, was never likely to expose all prospective donors who might transmit viral infection. Needle track marks on the lower arm of a person currently using drugs by injection might or might not have been identified during the process of taking a blood sample while evidence of injection elsewhere on the body would not. As was to be recognised at least by 1987,<sup>10</sup> the problem was related to the risk of parenteral transmission at any time during the individual’s life: injection of controlled drugs might have ceased long before the donor session or might have been a single act of an individual otherwise free from the use of illicit drugs.

**26.10** In the United Kingdom, the problem of drug use was dealt with under the Misuse of Drugs Act 1972, in which the range of offences recognised both the use and supply of controlled drugs as social problems that required to be addressed. On the evidence before

<sup>3</sup> The ISBTS Guide *Criteria for the selection of blood donors* [DHF.001.2672] applied a six-month cut off for measures aimed at reducing the risk of transmission of viral agents. See Chapter 18, *Collection of Blood – General*, paragraph 18.91, and paragraph 26.250 et seq below.

<sup>10</sup> Paragraph 26.20 below.

the Inquiry, it appears that drug use was not recognised as a problem in prisons until later in the reference period. In transfusion practice in the USA, intravenous drug was probably initially a problem, reducing somewhat as paid donation reduced and then ceased. There was a tendency, however, for paid donors, drug addicts and other disadvantaged members of society to be grouped together by commentators.

**26.11** Since the establishment of the Scottish National Blood Transfusion Association (SNBTA) in 1940, paid donation had not been a practical issue in Scotland, so far as transfusion and the manufacture of NHS blood products were concerned.<sup>11</sup> In other respects, however, Scotland experienced a similar range of problems.

**26.12** In 1973 the WHO published a report of a meeting of an expert scientific group on viral hepatitis.<sup>12</sup> In a section on 'Changing patterns of infection in certain developed countries', the report commented on an increasingly large proportion of cases of Hepatitis B infection, particularly among males in the 15–29 year age group, suggesting a likely association with the illicit use of drugs.<sup>13</sup>

**26.13** In December 1975 a *World in Action* television programme, 'Blood Money', was broadcast in the UK. The programme was about the risk of transmission of hepatitis from blood products manufactured by US commercial companies using blood taken from high-risk paid donors.<sup>14</sup> Professor Arie Zuckerman, who was to play a central role in developing policy advice on blood transfusion in the UK, was quoted in the programme:

Well it's been recognised for a number of years now that bought blood does carry a higher risk. And it's difficult to actually pinpoint the reason, but it seems that individuals who are willing to sell their blood are normally from a background which appears to be rather poor socio-economically.

In the past, many of them were alcoholics and indeed the well known dictum which originated in the United States was Ooze for Booze. This has recently been replaced by perhaps a more serious element, namely drug addicts.<sup>15</sup>

**26.14** Two US researchers, Dr Harvey Alter and Dr Leonard Seeff, commenting on commercial blood collection, noted that:

Prior to the advent of hepatitis serological assays, by far the most important hepatitis risk factor identified was the origin of the donor blood.<sup>16</sup>

**26.15** By 1975, when Professor Zuckerman made his observation that 'bought blood does carry a higher risk', the broad group of individuals thought to present risk had not changed. Risk was associated with poor, socio-economically disadvantaged people but the characteristic behaviour that was the subject of comment had moved from alcohol to drug use.

<sup>11</sup> As noted in Chapter 17, *Blood and Blood Products Management*, paragraph 17.20, the Scottish National Blood Transfusion Association (SNBTA) was formally constituted on 5 March 1940. The organisation was renamed the Scottish National Blood Transfusion Service (SNBTS) in 1974. Paragraph 17.13 notes that small payments or other forms of reward had been made to donors in some areas in Scotland prior to the establishment of the SNBTA but that, with the formation of a national service, paid donation was phased out and voluntary donations became the norm.

<sup>16</sup> Alter and Seeff, 'Transfusion-associated hepatitis' in Zuckerman, AJ and Thomas, HC (eds) *Viral Hepatitis: Scientific Basis and Clinical Management*, 1993, Churchill Livingstone, Oxford, page 473

**26.16** The move away from collecting blood from paid donors began in the USA in the early 1970s as a result of the higher incidence of post-transfusion hepatitis associated with such donations. In 1974, Alfred Prince and others reported that, in their series of investigations, the risk of non-B Hepatitis was 10 times higher among recipients of blood obtained from commercial sources than among those given blood from volunteer donors.<sup>17</sup>

**26.17** It appears that, as paid donation in the USA was phased out, there was greater emphasis on identifying donor groups that presented increased risk of transmission of infection by reason of their behaviour. In a paper published in February 1976 on 'Blood Transfusion and Transmissible Disease', Dr John Wallace, at that time Director of the Glasgow and the West of Scotland BTS, noted that, '[g]roups known to have a high prevalence of antigenaemia [a high prevalence of Hepatitis B antigen] include immigrants or returned travellers from tropical areas, drug addicts, male homosexuals, prisoners, the tattooed and the sexually promiscuous'.<sup>18</sup> Although Scotland did not have an issue with paid donation, parts of the country, and in particular Edinburgh, came to be associated with serious drug use and there was increasing emphasis on excluding those using intravenous drugs from donation.

**26.18** The International Society of Blood Transfusion (ISBT) Guide *Criteria for the selection of blood donors* published in 1976,<sup>19</sup> in a section on viral hepatitis, listed groups of prospective donors who should be excluded from donating blood. The list included those 'suspected to be parenteral drug addicts'.<sup>20</sup> The use of the present tense 'to be' may suggest a focus on current, or at least recent, drug use. In addition, in a section on medication and drugs, the document stated:

Those who admit to occasional use of marijuana, LSD, and similar hallucinatory drugs may be accepted if they have not taken any in the previous 72 hours and their arms show no signs of needle-puncture marks or scars indicating that they might have been taking drugs parenterally. Regular users of hallucinatory drugs may, however, be unable to give an accurate history with regard to injectable narcotics or exposure to hepatitis; for this reason they should be disqualified.<sup>21</sup>

**26.19** Dr McClelland received the ISBT documents but did not know whether this guidance influenced thought and practice in Scotland at the time.<sup>22</sup> His general evidence, however, was that evidence of drug use disqualified potential donors.

**26.20** From 1974, the CSA had the duty of providing blood supplies for transfusion and for the production of blood fractions. However, the Regional Transfusion Centres remained largely autonomous entities as far as many professional matters were concerned. The SNBTS stated that, in respect of blood donor selection, the Regional Transfusion Director (RTD) and his/her consultant colleagues determined their own local policies and issued guidance to medical and nursing staff.<sup>23</sup> From 1977 to about 1982, when the SESBTS produced their own guidance, all RTDs used the *Memorandum on the Selection, Medical*

*Examination and Care of Blood Donors* prepared on behalf of the NBTS in 1977 and amended in 1983, 1985 and 1987 for guidance. In 1985, it was agreed that the SNBTS should prepare guidance for Scotland based on the SESBTS documents. The 1977 version of the NBTS *Memorandum* stated that ‘illicit drug taking if suspected or admitted should debar’.<sup>24</sup> That wording persisted in the 1983 version of the same memorandum but, in addition, under the section on ‘Medical History’ the document indicated in relation to ‘Drug Abuse’ that disqualification should occur.<sup>25</sup> The 1987 edition advised staff who might be concerned that a potential drug user had presented as a donor to consult the sister or doctor and stated: ‘Anyone who has ever injected drugs to be deferred permanently’.<sup>26</sup>

**26.21** The express recognition in 1987 that risk may have been created in the past as much as by current IVDU was a significant change of emphasis. The 1979 edition of the Department for Health and Social Security (DHSS) *Standards for the Collection and Processing of Blood and Blood Components and the Manufacture of Associated Sterile Fluids*, applicable throughout the United Kingdom, had stated that ‘[i]llicit drug taking’ would ‘disqualify a person from acting as a donor’.<sup>27</sup> As in the 1977 edition of the NBTS *Memorandum on the Selection, Medical Examination and Care of Blood Donors*, the question whether the prospective donor had ever taken drugs was not expressly addressed at that time.

**26.22** The ISBT guidance of 1976, that suspected drug addicts should be excluded from donating blood, was not universally followed. The response by the Edinburgh and South East of Scotland BTS to a report of the Medicines Inspectorate, published in January 1983, noted that, as a routine for all donors, a detailed health check questionnaire had been introduced.<sup>28</sup> The questionnaire did not, however, ask if the donor had a current or recent history of intravenous drug use, far less if they had ever injected drugs.<sup>29</sup> In addition, as noted in paragraphs 26.4 above, guidance on donor selection made available to staff in the Edinburgh and South East of Scotland BTS at that time, was to the effect that a history of intravenous drug use did not result in indefinite deferral but instead resulted in deferral for a period of at least six months, ‘because of the risk of serum-hepatitis’. However, in response to AIDS in 1983 a leaflet, ‘AIDS and Blood Transfusion’ issued by the Edinburgh and South East of Scotland BTS, included IVDUs among those at risk of contracting AIDS and asked them to avoid giving blood until a screening test was available.<sup>30</sup>

**26.23** A donor leaflet apparently in use by the Glasgow and West of Scotland BTS in 1983 listed a number of matters to be reported by prospective donors to the doctor in charge of the session.<sup>31</sup> It asked whether the donor had experienced a serious illness such as jaundice. Again, the leaflet did not ask whether the donor had a current or recent history of intravenous drug use or if they had ever injected drugs, nor were those questions contained in a donor leaflet seemingly in use in England and Wales in 1983.<sup>32</sup>

<sup>30</sup> Leaflet [SNF.001.3397] at 3398

<sup>31</sup> Glasgow and West of Scotland BTS Leaflet [PEN.013.1395]. Dr Mitchell has explained that though the date 6/6/83 is marked on the leaflet it was issued in about late April 1983.

<sup>32</sup> NBTS Leaflet [SGF.001.0397]. Professor Leikola of the Finnish Red Cross Blood Transfusion Service was examined on how donor sessions were conducted in Finland and did not think that the donor questionnaire in use in Finland in the late 1970s/early 1980s included a question as to whether the donor had ever injected or used drugs. That, however, changed in 1983 with the arrival of AIDS: Day 13, pages 20 and 73.

In this respect the Glasgow and West of Scotland leaflet was consistent with Mrs Prior's evidence about practice in the west of Scotland during the 1970s.

**26.24** In his evidence to the Inquiry, Dr McClelland stated that he could only be confident that the majority of staff would have asked donors about current or past drug use only from the early 1980s, when there was an awareness of AIDS.<sup>33</sup> Dr Mitchell was asked whether, in the late 1970s and early 1980s, it was the practice at donor sessions to ask donors if they had ever injected drugs. He replied, 'I think – no, I don't think so in the 1970s. I can't remember it being there. It might have been later in the consideration of AIDS'.<sup>34</sup> Professor John Cash, Medical Director of the SNBTS during much of the reference period, did not know whether donors were asked whether they had ever injected drugs but said, 'my gut feeling is certainly when we got into the area of AIDS, there was great difficulty for some of our staff asking very straight questions about people's lifestyles'.<sup>35</sup>

**26.25** Prior to the advent of AIDS, therefore, evidence of current or recent intravenous drug use, whether in the prospective donor's response to enquiry or by observation, had been recognised in published statements as a ground for exclusion for a considerable period. However, before the advent of AIDS there appears to have been no direct questioning of donors in relation to any recent or current history of intravenous drug use. Evidence of use of intravenous injection of drugs at any time in the past was beginning to be recognised as a ground for exclusion only in the later 1980s, as it came to be understood that NANB Hepatitis viraemia might persist indefinitely. Prior to the advent of AIDS reliance was placed on observation and donor responses to questionnaires.

## Prison collections

### *International guidance*

**26.26** There was limited guidance in international literature on the practice of collecting blood in penal institutions. The 1971 *Guide to the Formation and Operation of a Transfusion Service*, already mentioned in paragraph 26.8 above, recommended that countries setting up a donor recruitment scheme should take initial steps to form panels of donors within groups such as the armed forces, the police, large industrial or commercial undertakings, universities, prisons and social or religious foundations.<sup>36</sup> Since it was aimed at those with the responsibility of establishing and developing transfusion services in their own countries, it focused on the effectiveness of management of the new services rather than on specific risks.

**26.27** In defining preferential sources of blood, the aim of the 1971 Guide was to facilitate the early stages of development of a service where none had previously existed and the reference to the collection of blood from prisons has to be seen in that context. In addition, the *Guide* was written before, or at least around the same time as, evidence began to become available in the UK that prison donors had a higher prevalence of 'Australia antigen' (the early name for the Hepatitis B surface antigen, HBsAg) than non-prisoner donors. This is discussed more fully in Chapter 15, *Knowledge of Viral Hepatitis 2 – 1975 to 1985*. Having regard to these factors, it is not possible to rely on the recommendation in

<sup>33</sup> Day 9, pages 22–23

<sup>36</sup> WHO Guide [PEN.002.0462] at 0475. The guide was edited by CC Bowley, KLG Goldsmith and W d'A Maycock on behalf of the World Health Organization, the International Society of Blood Transfusion and the League of Red Cross Societies, with contributions from experts from England, Canada, France, the Netherlands and Switzerland.

the *Guide* to form donor panels in prisons in drawing particular inferences about practice in Scotland.

**26.28** The ISBT *Criteria for the Selection of Blood Donors* proposed in 1976 that prospective donors should be excluded if they were ‘inmates of a correctional institution’.<sup>37</sup> As noted in paragraph 26.19, Dr McClelland did not know whether the ISBT guidance influenced thought in Scotland in the late 1970s and early 1980s.

**26.29** In 1978 the WHO Expert Committee on Biological Standardization published a report.<sup>38</sup> The report noted that it had been agreed that it would be useful to have a single set of requirements applicable to all organisations and laboratories involved in the collection of blood for fractionation and for blood products. It also set out a range of proposals in an Annex on *Requirements for the Collection, Processing and Quality Control of Human Blood and Blood Products*.<sup>39</sup> In respect of individuals who might fall within proscribed groups, the report stated:

Donors shall have a negative history of viral hepatitis, of close contact with an individual with hepatitis within six months, of receipt within six months of human blood or any blood component or fraction that might be a source of transmission of viral hepatitis, or of tattooing within six months.

....

Donor populations showing a prevalence of acute or chronic hepatitis higher than that found in the general population should be avoided for collection both of single donor products (whole blood and its components) and of plasma for pooling for the manufacture of plasma fractions known to be capable of transmitting hepatitis, such as clotting factor concentrates.<sup>40</sup>

**26.30** As regards the last recommendation quoted, Professor Juhani Leikola of the Finnish Red Cross Blood Transfusion Service stated in his evidence to the Inquiry that he would not place much weight on a recommendation relating to the avoidance of a donor population showing ‘a higher prevalence of acute or chronic hepatitis than in the general population’. He explained that this is because (i) direct markers of disease (eg the presence of antigen) should be used when identifying a group with a higher prevalence of disease, rather than indirect markers such as ‘acute or chronic hepatitis’ and (ii) the recommendation does not say how much higher the prevalence of disease should be in a donor group for that group to be excluded. He also commented that the committee that produced the recommendation comprised biologists, virologists and fractionators rather than those with practical experience of blood collection or transfusion.<sup>41</sup> Subject to those reservations, which are accepted to be valid, the last paragraph would have applied to prison donor populations in Scotland in the later 1970s when data on the prevalence of HBsAg in prison populations became available.<sup>42</sup> Prison populations as such were not, however, targeted.

<sup>37</sup> ISBTS Guide *Criteria for the selection of blood donors* [DHF.001.2672] at 2684

<sup>38</sup> WHO Expert Committee on Biological Standardization – Twenty-ninth Report [LIT.001.3627]

<sup>41</sup> Day 13, pages 57–58

<sup>42</sup> Dr McClelland – Day 9, page 129

**26.31** None of the Scottish or UK guidance documents on the selection of donors contained any reference to the collection of blood from prisons or young offenders' institutions at this period. Reservations about collections from prisoners were expressed in the Annual Report of the Edinburgh and South East of Scotland BTS for 1973–74, which included an address given by Professor Anthony Ritchie, Chairman of the Central Consultative Committee of the SNBTS.<sup>43</sup> He contrasted donations of blood drawn from prisoners, where 'there is little enough "voluntary" aspect to donation', with the general British system in which virtually all blood donors were true volunteers.<sup>44</sup> There is no evidence that his views influenced practice at that time, however.

**26.32** The SNBTS Regional Directors were aware of the NBTB *Memorandum on the Selection, Medical Examination and Care of Blood Donors* and there was evidence that the RTDs based their donor selection policies on that document.<sup>45</sup> However, in this, as in other matters, the individual Transfusion Directors will have exercised their own discretion in the manner in which they did so. They had a high degree of autonomy in donor selection and it is not possible to state that there was uniform practice.

### *International practice*

**26.33** Reaction against collection in prisons started early in the 1970s in the United States of America. Professor Richard Titmuss' book *The Gift Relationship* had a powerful impact.<sup>46</sup> When he published, in 1970, it was well-established in the USA that there was a relatively high prevalence of serum hepatitis among certain donor populations and, in particular, among the 'cloistered residents of Skid Row' and prisoners.<sup>47</sup> The risk of transmission of infection associated with these groups was said to be at least ten times as great as that arising from voluntary donors.

**26.34** It was not until 8 June 1995 that the US Food and Drug Administration (FDA) issued a formal recommendation that current and recent inmates of correctional institutions should be deferred, for a period of 12 months from the last date of incarceration, as donors of whole blood, blood components, source leukocytes and source plasma.<sup>48</sup> While this timing may appear surprising, the FDA recommendation has to be seen in the context that blood transfusion practice in the USA was regarded as a matter for local rather than Federal regulation. In a paper submitted to the Inquiry, 'Collection of blood in prisons', for example, the SNBTS stated:

However as [Douglas] Starr recorded in his book, 'Blood' 'the Americans had stopped harvesting prison plasma for clotting factor by 1983 ...'. Although this was never formally documented, this is believed to be the case.

There was an informal (unpublished) agreement in late 1982 between the FDA and commercial companies to cease prison sessions ... (although it does appear that the American Red Cross may have still been collecting in prisons in 1983).<sup>49</sup>

<sup>43</sup> Annual Report [SGH.003.1305] at 1313

<sup>44</sup> Ibid [SGH.003.1305] at 1316

<sup>45</sup> Dr McClelland – Day 9, page 92 and Dr Gillon – Day 11, page 46. In addition, as noted below, the SNBTS had an input into at least the 1983 version of the Memorandum, through Dr Brookes' membership of the relevant Working Party.

<sup>46</sup> Titmuss, R. *The Gift Relationship*, 1970, George Allen and Unwin, London. Titmuss compared the blood donor system in England and Wales with that in the USA. See discussion in the Preliminary Report, paragraphs 5.39 to 5.42.

<sup>48</sup> Memorandum dated 8 June 1995 by the Director, Center for Biologics Evaluation and Research, FDA, to all registered blood establishments, on 'Recommendations for the deferral of current and recent inmates of correctional institutions as donors of whole blood, blood components, source leukocytes and source plasma'. [PEN.012.0173]

<sup>49</sup> Collection of blood in prisons [PEN.018.1521] at 1530. See also the reference at the meeting of the English Transfusion Directors on 6 October 1971, noted below at paragraph 26.61, that the American Red Cross had from July 1971 stopped collecting blood from donors in correctional institutions.

**26.35** In addition, the Inquiry does not have sufficient evidence about the practice in the USA to place the FDA recommendation in its proper context or to draw any meaningful conclusions from it. In particular, the Inquiry has not heard evidence on how much blood was collected in US prisons, by which organisations and when, or the purpose to which any such blood or plasma so collected was put. A detailed investigation of these matters was outwith the Terms of Reference of the Inquiry. For these reasons, it would be difficult to draw any meaningful conclusions from a consideration of the FDA recommendation in isolation. Douglas Starr's comments appear to be a more reliable indication of when the practice stopped.

**26.36** Internationally, practice varied. The Canadian Red Cross ceased collecting donations from prison inmates in 1971 after results from the Hepatitis B surface antigen test demonstrated conclusively that prison inmates in Canada had a significantly higher prevalence of hepatitis than the rest of the population. The decision was made as a matter of Red Cross policy and not in response to regulation.<sup>50</sup>

**26.37** A study in Finland of carriers of Hepatitis B antigen and transfusion hepatitis was published in 1974.<sup>51</sup> The study found a higher incidence of Hepatitis B antigen among prisoner donors when compared with the non-prison donor population.<sup>52</sup> The author of the report, Dr Timo Helske, commented:

The high frequency of carriers among prisoners (0.9 per cent) was consistent with the findings by other investigators.

There is at present no satisfactory explanation for these differences between various population groups. Drug addiction has been suggested as one possibility, since drug addicts are found most frequently among young adults. Illicit use of drugs no doubt accounts for a part of the acute cases of hepatitis type B and consequently for a few of chronic antigenaemia with chronic hepatitis. Together with tattooings this might at least to some extent explain the high prevalence of carriers among prisoners.

The HBAG carrier state has been related to socioeconomic and hygiene factors. A low socioeconomic standard might favour the circulation and dissemination of hepatitis B virus.<sup>53</sup>

**26.38** Dr Helske went on to note that in Finland, 'prisoners are indisputably a risk group in which a high HBAG carrier rate appears to be associated with a high risk of acute and chronic hepatitis'.<sup>54</sup> By the time Professor Leikola joined the Finnish Red Cross Blood Transfusion Service in February 1975, a decision had already been taken to stop collecting blood in prisons.<sup>55</sup> Professor Leikola considered it likely that the decision was taken on the basis of Dr Helske's study. He commented on two factors. Firstly, it was realised that not all Hepatitis B cases were recognised by the HBsAg test and that a good part of the people who screened negative were still carrying the Hepatitis B virus, then known to be the cause of potentially serious disease. Secondly:

<sup>50</sup> Krever Commission of Inquiry on the Blood System in Canada, Final Report, Part III, page 618, <http://publications.gc.ca/collections/Collection/CP32-62-3-1997-2E.pdf> (last accessed 7 January 2015)

<sup>52</sup> Ibid [LIT.001.3562] at 3571–72. The mean HBAG carrier rate among donors was found to be 0.16% whereas the frequency among prison donors was found to be 0.9% (at 3614).

<sup>53</sup> Ibid [LIT.001.3562] at 3577–78

<sup>54</sup> Ibid [LIT.001.3562] at 3611

<sup>55</sup> Written Statement by Professor Leikola, 'Donations in prisons and donors with jaundice' [WIT.003.0027]. See also Day 13, page 25.

In addition to that, [there] was the possibility of other viruses existing and [the] probable existence of other viruses. So if we would avoid transfusing Hepatitis B, that was not detectable by those tests that were used at that time, then an additional factor was that we would also avoid those viruses that presumably were also within prisoners.<sup>56</sup>

**26.39** When preparing his written statement to the Inquiry, Professor Leikola had discussed the collection of blood in prisons with Dr Helske. In oral evidence, Professor Leikola stated:

I discussed this matter with him and he said that he didn't remember when it was formally decided but he told me that when he showed his findings to Professor Nevanlinna,<sup>57</sup> Professor Nevanlinna was, let's say, almost shocked, when he saw the difference between the prisoners and the donors in the general population. They had also thought that maybe within [the] army, where the conscripts would come voluntarily and in groups and so on, that was not a closed institution but not very far from that. They were a little bit afraid whether there would be a higher incidence of Hepatitis B also and they were quite relieved when they saw that it was 0.2 per cent, which was the same as from mobile units from the Helsinki larger area.

Dr Helske told me that after he had shown these results to Professor Nevanlinna, these were discussed by the senior staff and everybody agreed that, because of this high prevalence, it was probably much safer to stop the donations at prisons, especially because only a small proportion of the blood supply was coming from prisons.

If I may add here, I have the feeling that these results were discussed at the meeting of the Council of Europe expert committee in May 1974. I was not personally involved so I have been thinking of these connections, because in the same group there was Dr Maycock from the UK. He was representing the UK to that group. There were Dr Moore, Dr Freiesleben from Copenhagen, Dr Hogman from Stockholm who wrote this ISBT recommendation,<sup>58</sup> including also avoidance of prisons as a source of blood.

So I think that this has been discussed at that time within a larger European group, especially because Dr Helske refers here to the finding being of similar magnitude as in other Scandinavian countries. And I'm quite sure that he refers to Sweden and Denmark and therefore these people were aware of the higher incidence of Hepatitis B antigen within prison inmates.<sup>59</sup>

**26.40** The practice of other European countries in respect of the collection of blood in prisons is helpfully shown in a 2004 survey conducted by the European Blood Alliance (EBA).<sup>60</sup> The Table 26.1 in the Appendix to this chapter contains a summary of replies of the EBA member states.<sup>61</sup>

<sup>58</sup> That is, the 1976 ISBT guidance referred to above [DHF.001.2672]

<sup>59</sup> Day 13, pages 38-39

<sup>60</sup> The European Blood Alliance is an association of not-for-profit blood establishments, with 22 members throughout the European Union and EFTA States.

<sup>61</sup> The table is appended to the SNBTS paper, 'Collection of blood in prisons' [PEN.018.1521] at 1541. (In fact, as can be seen from the next table, collections in prisons in the west of Scotland region continued into early 1984, albeit on a greatly reduced scale, ceasing in March of that year.)

**26.41** There was a clear difference of practice among European blood transfusion services in respect of collecting blood from prisoners. In particular, as reflected in the table:

- Some countries never collected blood from prisoners (Denmark, the Netherlands<sup>62</sup> and Eire).
- Some countries introduced a permanent or temporary deferral of blood collected from prisoners in the 1970s (Switzerland, 1970;<sup>63</sup> Belgium, mid-1970s; Finland, 1975).
- Some countries ceased the collection of blood from prisons in the 1980s (England and Northern Ireland, both 1983; Scotland, 1984; Luxembourg, 1985; France, 1985–89).<sup>64</sup>
- Other countries did not introduce permanent or temporary deferral of blood donation by prisoners until the 1990s (Portugal, 1990; Austria, 1995; Germany, 1996; Norway, 1997).<sup>65</sup>

### Collection of blood in Scottish penal institutions

**26.42** The evidence obtained by the Inquiry indicates that blood was collected from penal institutions in Scotland from at least 1957 until the last prison session took place in each individual region.<sup>66</sup> The last prison donor sessions took place respectively in the south east (Edinburgh) on 22 December 1981; north (Inverness) on 24 February 1983; north east (Aberdeen) on 28 July 1983; east (Dundee) on 2 August 1983; and west (Glasgow) on 25 March 1984.<sup>67</sup>

**26.43** The donations collected in each Scottish RTC between 1971 and 1984, as shown in extant records, are shown in Table 26.2 in the Appendix to this chapter.

**26.44** The percentage of total blood donations in Scotland collected from penal institutions fell from 2.38% in 1975 (5915 of 248,558 donations) to 0.11% in 1984 (342 of 308,617 donations), with an annual average over that period of 1.097%.<sup>68</sup>

<sup>62</sup> It was also Professor Leikola's understanding, based on discussion with Professor van Aken of the Netherlands Red Cross Blood Transfusion Service, that the Netherlands never collected blood in prisons: Day 13, pages 58–59

<sup>63</sup> See also the evidence of Professor Leikola – Day 13, pages 59–62

<sup>64</sup> See also the evidence of Professor Leikola – Day 13, pages 62–64

<sup>65</sup> See also the discussion in the SNBTS paper 'Collection of blood in prisons' [PEN.018.1521] at 1529

<sup>66</sup> The commencement of the practice of prison collection in 1957 is taken from the SNBTS paper 'Collection of Blood in Prisons' [PEN.018.1521] at 1525.

<sup>67</sup> 'SNBTS Blood Collection 1975–1991' [PEN.010.0003] at 0012. The prisons visited by each RTC are listed in 'SNBTS Blood Collection 1975–1991 – further response' [PEN.010.0026] at 0028.

<sup>68</sup> In fact, these figures are likely to be slightly higher as the number of prison donations collected from the North RTC (Inverness) are not available as a result of records being destroyed in a flood – see para 1 of 'SNBTS Blood Collection 1975-1991' [PEN.010.0003]

**26.45** The donations collected by each Scottish RTC from penal institutions between 1971 and 1984, as shown in extant records, were:

**Table 26.3: Donations collected at Penal Institutes in each Scottish RTC 1971–84**

Year	Region				
	West RTC	South east RTC	East RTC	North east RTC	North RTC*

\* From 1971 to 1983 NRTC visited 1 prison, Inverness (Porterfield) Prison. Donation numbers are not available as the records were lost in a flood.

**26.46** With the exception of 1976, in each year between 1974 and 1984, Glasgow and the West of Scotland collected the greatest number of donations from prisons (averaging about 59% of the total for the period). The West, having the largest centre of population in Scotland, accounted for around 47–50% of all donations collected in Scotland over the period for which total donation values are available. Prison collections made a proportionately higher contribution to total donations in that region than elsewhere in Scotland.

**26.47** Caution is needed when interpreting these figures on an annual basis.<sup>69</sup> In all regions, at some periods while the practice continued, prison donations were collected at certain times in the year rather than throughout the year, in some instances to plug a gap in the supply from the non-prison population. For a local holiday week, the prison collection might have been more than half the transfusion centre's total supply and critically important.<sup>70</sup> As Professor Cash understood it from Dr Mitchell, it was believed that the Glasgow Fair holiday would have created a significant problem but for collections in prisons at certain periods.<sup>71</sup> The annual average underestimated the impact that would follow from ceasing prison sessions during such vulnerable periods.

<sup>69</sup> Professor Cash's Witness Statement [WIT.003.0120] at 0120–21

<sup>70</sup> Professor Cash – Day 10, page 18

<sup>71</sup> Ibid page 19

**26.48** The pattern of collections in prisons has to be considered in the light of historical facts, so far as they can be ascertained. Much of the written material dealt with drug addicts, paid donors and inmates of penal institutions together and is taken as a whole where necessary, since context and the sense of the evidence may be lost by selective citation.

### *Conduct of prison sessions*

**26.49** A question arises whether, during the periods when blood was collected in prisons, borstals and other similar institutions, any modification of the procedures at routine donor sessions was adopted to reflect the particular circumstances of the closed environment and the particular population involved.

**26.50** So far as SNBTS policy was concerned, the conduct of donor sessions in penal institutions was, as far as possible, identical to that of donor sessions anywhere else. The sessions were arranged through a member of staff in the institution, usually the director, who would delegate organisation to a medical officer. The dates were set well in advance. The same mix of personnel attended. SNBTS staff would work on the premise that the donors were volunteers when they attended. Dr McClelland acknowledged that there would be discussion around the nature of volunteering in a penal institution. For the purpose of the sessions, however, it had to be accepted that the donors were volunteers. Dr McClelland was unaware of there being any ‘unique’ or ‘explicit’ measures for sessions in prisons.<sup>72</sup>

**26.51** Superficially, the structure of donor sessions was in accord with that description. The evidence of Mrs Rosalind Prior on the practice in Glasgow and the west of Scotland in the early 1970s up to the beginning of the reference period has been set out in Chapter 18, *Collection of Blood – General*, paragraph 18.38.

**26.52** Mrs Prior’s account emphasised the degree of dependence on donor recollection and reliability that was inherent in the system. In relation to prison sessions, she said:

When we attended the prisons to collect blood from prisoners it was the same process. However, as it was generally a bigger set-up we would generally have more staff present. During the year the mobile unit attended Shotts, Polmont, Corntonvale, Lowmoss and Barlinnie prisons. The unit always attended Barlinnie Prison for the two weeks of the Glasgow Fair holiday in July. My impression was that the incentive for prisoners to donate blood was that it was just a way of getting away from what they would normally be doing. However, the prisoners at Barlinnie Prison, Glasgow told me that they had been informed by the “screws” (prison officers) that if they donated blood they would be given a cigarette and sugar. They were not pleased when they found out that this wasn’t the position ... I am asked whether there was any pre-selection/exclusion by the prison authorities of prisoners who were allowed to donate blood. I am unaware of whether there was or was not such a policy.

....

There was no difference in the procedure, including questions asked, between prison and other donor sessions. I do not recall any suggestion being made that blood collected from prisons was different from blood collected elsewhere.<sup>73</sup>

---

<sup>72</sup> Day 9, pages 18–19 and 26

<sup>73</sup> Mrs Prior’s Written Statement [PEN.019.0107] at 0109–10

**26.53** Mrs Prior had identified two differences between donation by prisoners and donation by members of the general public. There was an opportunity to escape prison routine, even for a short period, and there was the potential for incentives to be offered, genuine or otherwise. So far as Mrs Prior's evidence is concerned, neither of these differences appears to be material for present purposes. A different perspective was presented by Dr Ewa Brookes. Prior to her appointment as Regional Director at the Dundee RTC in May 1981, Dr Brookes had worked as a Consultant in the South London RTC. She scheduled herself as session medical officer on three successive sessions in a London prison, possibly in 1978–79. She summarised her experience:

- While volunteers might mention a past history of jaundice, or a self-limiting illness long ago, any admission of recent injury, or an illness which might be a sign of weakness, eg heart disease or diabetes, was never made.
- If admission was made (one man told her of a myocardial infarct [heart attack] three weeks before), it was whispered, for fear of making him appear vulnerable to the other prisoners.
- Apart from the obvious attraction of a group of professionally courteous women as donor assistants, prisoners had a change of activity and an easier day after donating, so were keen to do so.<sup>74</sup>

**26.54** The third point gives a slightly different colour to the points made by Mrs Prior. The other two draw attention to an aspect of institutional life that made it much more likely that relevant information would be withheld by institutional donors than donors from the general public. Dr Brookes' response indicates that she was concerned about the practice. Following these sessions, she met the Prison Medical Officer of the London prison she had attended (a senior and very busy man), indicating the reasons for the BTS prison sessions and the expectation that volunteers were pre-screened. She was forcefully advised that he had duties in more than one prison and many much greater problems than those of donor selection. The information was reported to her Director and discussed at the Senior Staff Meeting in her Transfusion Centre. It reinforced previously held concerns and the decision was made to phase out sessions in prisons and young offenders institutions.<sup>75</sup>

**26.55** The Inquiry sought the views of the Scottish Government about the role of prison medical officers. It was explained:

The Secretary of State had a statutory power to appoint prison officers, including medical officers (being medical practitioners duly registered under the Medical Acts), but in practice medical services were the responsibility of each respective prison; there was no national prison medical service. Each prison, other than Barlinnie which directly employed two or three full-time medical officers, had a contract with a local surgery or health centre. There could therefore be a number of different GPs providing medical services to each prison on a part-time basis. Medical officers received very little, if any, guidance from prison management, and the expectation was that they would

---

<sup>74</sup> Dr Brookes' Witness Statement [WIT.003.0057] at 0059

<sup>75</sup> Ibid [WIT.003.0057] at 0060. Dr Brookes went on in her statement to say: 'The desirability of stopping donor sessions in prisons and other corrective establishments was taken to an NBTS Directors meeting where it was felt that, in view of the Government recommendation outlined above [i.e. that prisoner donation was consistent with rehabilitation], this decision should not be made nationally without further consideration'. The consideration given by the NBTS to prison collection and government policy in that regard is discussed further below, in the chronological narrative section.

bring knowledge and independence from their respective general practices. This meant that the practice between, and even within, prisons was varied.<sup>76</sup>

**26.56** As regards the involvement, if any, of prison medical officers in the collection of blood at prisons the Scottish Government advised:

Up until 1983 SNBTS might visit each prison twice a year. Usually the chief nurse officer in each prison was the SNBTS contact and authorised the routine visits. Medical officers were not involved and, not attending the prison every day, often might not even have known the visit was taking place. Also, given that medical officers dealt with their prison patients on the same basis as community patients, in terms of confidentiality, the identities of those known to have been misusing drugs were not disclosed to SNBTS on a routine basis.

It is likely that the SNBTS doctors who attended the donor sessions would have been able themselves to identify those prisoners who were misusing drugs intravenously, through sight of needle marks.<sup>77</sup>

**26.57** In answer to a query as to whether any steps were taken by those in the prison medical service and/or by the Scottish Prison Service to prevent prisoners who were dependent on drugs or had a history of drug use from attending donor sessions in penal establishments, the Scottish Government replied:

We have been unable to ascertain whether any such steps were taken. Neither medical officers within prisons nor the government staff in the Scottish Prison Service were involved with SNBTS visits to prisons.<sup>78</sup>

**26.58** In summary, there was no evidence before the Inquiry that any additional steps were taken at prison donor sessions in Scotland to seek to screen out higher risk donors such as those who had ever injected drugs. The response from the Scottish Government noted above suggests that no such additional steps were taken, as does the evidence of Dr McClelland and Mrs Prior that there was no difference in the procedure, including questions asked, between prison and other donor sessions.

**26.59** Whether that was appropriate depends to a considerable extent on whether there were grounds for distinguishing donors in penal institutions from donors in the general public. The question is whether there were features of the prison population that gave rise to risks that were relatively greater than among donors from the general public. This question is discussed below.

### **Chronological narrative of United Kingdom views on prison collection**

**26.60** In the absence of any comprehensive statement of developing policy in the United Kingdom, and Scotland in particular, it is appropriate to set out a chronological statement of the evidence obtained.

---

<sup>76</sup> Letter dated 18 July 2011 from Ms Robson of the Scottish Government Legal Directorate to the Inquiry [PEN.012.1904], para 2, in response to a list of questions by the Inquiry [PEN.012.1782]

<sup>77</sup> Letter dated 18 July 2011 from Ms Robson of the Scottish Government Legal Directorate to the Inquiry [PEN.012.1904] at 1905–06, para 4

<sup>78</sup> Ibid [PEN.012.1904] at 1906, para 6

**1970-1974**

**26.61** At a meeting of the English and Welsh RTDs on 6 October 1971,<sup>79</sup> it was noted that the American Red Cross had stopped collecting blood from donors in correctional institutions from July 1971, because it was generally accepted in the USA that the incidence of infective, but Australia antigen-negative, donations was higher among prisoners than from voluntary unpaid donors and because the incidence of Australia antigen among prisoners was ten times greater than among voluntary unpaid donors.<sup>80</sup> At the time, all RTCs collected blood in prisons, borstals or other similar institutions. The RTDs reported differing experiences and impressions.

**26.62** Several RTDs did not consider that the association of donations from such sources with cases of hepatitis was any greater than that of donations from other donors. Two reported a greater incidence of Australia antigen-positive (Au-positive: that is, positive for the Hepatitis B surface antigen HBsAg) results among prisoners than among other donors. Recorded discussion included comments on the great difficulty in following up prisoners found to be Au-positive and arranging for confirmatory tests, particularly after prisoners had been discharged. In one prison the names of donors were not given to the RTC. One attendee at the meeting, Dr Grant, said it was sometimes difficult to keep any record at all of prisoner donors. Another Director suggested that prison and borstal governors should be asked to prevent any individuals known to be or to have been a drug user from volunteering as a donor. The outcome was indecisive:

After further discussion the meeting ... decided that before considering whether to stop collecting blood in prisons etc. more information should be obtained about the association of such donations with cases of serum hepatitis.<sup>81</sup>

**26.63** The suggestion that prison authorities should be asked to prevent any individual known to be, or to have been, a drug user from volunteering as a donor came to naught. At a meeting of the English and Welsh RTDs on 12 January 1972,<sup>82</sup> several Directors reported that they had been informed by prison governors or medical officers that there were no drug addicts in the prisons concerned. It was suggested that any prisoner should cease to be a donor if their blood, whether HBsAg-positive or not, had been associated with a case of serum hepatitis. The minutes record that it was agreed to leave the matter until there was more information about the incidence of HBsAg-positive test results among inmates of prisons and borstals.<sup>83</sup>

**26.64** In March 1972 the *British Medical Journal* published a paper by Dr Wallace and colleagues at the Glasgow and West of Scotland RTC on the prevalence of Australia antigen in donors in that region.<sup>84</sup> During a period of one year all of 105,724 blood donations were tested for Australia antigen and its antibody using a modified immunoelectroosmophoresis (IEOP) test. It was found that, in donors tested for the first time, male prisoner donors had a significantly higher incidence of Australia antigen (0.65%) than non-institutionalised male donors (0.12%). In addition, non-institutionalised male donors had a higher incidence of Australia antigen than female donors (who had an incidence of 0.05%). Overall, the

<sup>79</sup> Minutes of Meeting [DHF.002.7687]. In accordance with normal practice, there was at least one representative from the Scottish National Blood Transfusion Association present at the meeting. Participants' names have been redacted from the minutes.

<sup>84</sup> Wallace et al, 'Total screening of blood donations for Australia (Hepatitis Associated) Antigen and its Antibody', *British Medical Journal*, 11 March 1972 [SGH.002.9831]

incidence of Australia antigen-positive donations among prison donors (0.65%) was just under seven times higher than that in males and females in the general public (0.10%). The authors stated:

The high incidence of Au antigen of ... 0.653% ... in men prisoners has no obvious explanation. Viral hepatitis is not a serious clinical problem in the two institutions concerned, and the positive donors are not drug addicts. What is not known is whether or not these men were Au positive at the time of their first imprisonment. The high incidence may be related to social habits and to hygiene.<sup>85</sup>

**26.65** Professor Leikola was of the view that, had he read Dr Wallace's article in 1972, he would probably have felt that the explanation for the higher prevalence of Hepatitis B in prison donors being due to 'social habits and hygiene' was a plausible one.<sup>86</sup> As noted below, his views were to change after reading Dr Helske's paper in 1975.

**26.66** The English and Welsh Regional Transfusion Directors met on 7 June 1972.<sup>87</sup> The Directors had made attempts to collect data reflecting the incidence of infection in the donor population from before the reference period. There was particular interest in the risk associated with prisoners, especially drug addicts. The results in England and Wales were reported.<sup>88</sup> An overall incidence of 1:1500 antigen-positive and 1:1300 antibody-positive donors was reported. No antigen- or antibody-positives were observed among 1449 armed forces donors (including US Air Force personnel). On the other hand, in two borstal institutions and two prisons, antigen and antibody were detected in one in 488 donors (total donations tested, 976). In a discussion on the incidence of Australia antigen in the general and other populations, it was noted that of 107 donations involved in 19 cases of serum hepatitis, the incidence among donors from prisons and borstals was the same as that among all donations collected, 'which might suggest that the risk attaching to blood from such donors (normally bled only once) was not, in fact, higher than that from new general public donors'.<sup>89</sup> The minutes note that, 'It was reported that RTC Edgware ... had discontinued collecting blood in prisons and borstal institutions'.<sup>90</sup> Various figures, based on small population sizes, were given for the incidence of Australia antigen in donations from prisoners and members of the public in different regions in England. The minutes note that, '[i]n view of these discrepancies the meeting agreed that further information should be collected before it was decided to discontinue collecting blood in prison and borstal institutions'.<sup>91</sup>

**26.67** The English and Welsh RTDs next met on 20 September 1972.<sup>92</sup> Detailed returns from the English regions indicated a significantly higher incidence of Australia antigen among prisoners than among the general and university populations.<sup>93</sup> By then, almost all donations were being tested and quarterly returns of positive tests were required.<sup>94</sup> The minutes record discussion of a donor who was found to be Australia antigen-positive

<sup>93</sup> Revised minutes of meeting of 20 September [DHF.002.8022] at 8026 (Appendix 1)

<sup>94</sup> Minutes of Meeting [DHF.002.8014] at 8019

in prison and, before the result could be confirmed or the donor informed, he had been released and all trace of him lost. The RTC of the region where he was thought to live and neighbouring RTCs had been informed. It was agreed that the names and addresses of untraced Australia antigen-positive donors should be sent under confidential cover to all RTCs. The minutes noted that Edinburgh and Glasgow RTCs were collecting blood from prisons and that, 'In Edinburgh the incidence of Australia antigen positive tests in prisoners is no higher than among the general population; in Glasgow the incidence in prisoners is significantly higher'.<sup>95</sup>

**26.68** The minutes include an appendix showing the incidence of Australia antigen among different groups of donors at the Sheffield, Tooting, Bristol, Cambridge and Wessex RTCs in 1971–72.<sup>96</sup> In each RTC the incidence of Australia antigen among prison donors was significantly higher than that among the general public. Overall, the incidence of Australia antigen in these centres among prison donors was 0.373% (22 Au-positive donors out of a total of 5903 prison donors), compared with an overall incidence of Australia antigen among the general public at these centres of 0.051% (175 Au-positive donors out of 342,948 donors). Investigations over the middle of 1972 had shown that the incidence among prison donors in these English regions, of just over seven times that in donations from the general public, was similar to the increased incidence of Australia antigen reported in prison donors in Glasgow and the west of Scotland.<sup>97</sup>

**26.69** The English and Welsh RTDs met on 26 September 1973.<sup>98</sup> Representatives from the Scottish Home and Health Department (SHHD) and the SNBTA were present. An SNBTA Director had also been present at the meetings held in October 1971 and June 1972. It was noted that the incidence of Australia antigen in prison donors was higher than in the general public.<sup>99</sup> It was recorded that the adjusted data appeared to show that the frequency of antigenaemia among members of the armed forces was similar to that among new donors from the general public. The minutes state:

The meeting considered whether NBTS should stop collecting blood in prisons. Seven directors<sup>100</sup>... thought prisoners should no longer be bled because the incidence of antigenaemia not detectable by IEOP was probably higher in this population than among the general public. Seven<sup>101</sup>... thought that screening for antigen gave adequate protection, and that blood collection in prisons should be continued until the statistical significance of the figures in RTD(73)25<sup>102</sup> had been examined. [Name redacted] undertook to arrange this. It was agreed that if it were decided to discontinue bleeding prisoners, the Department should inform the Home Office before any local action was taken.<sup>103</sup>

<sup>102</sup> The Inquiry has been unable to identify this document. It seems likely, however, that it contained information similar to that contained in the appendix to the minutes of the previous meeting ie [DHF.002.8022] at 8026

<sup>103</sup> Minutes of Meeting [DHF.002.7960] at 7967

**26.70** At a meeting of the SNBTA Directors on 4 October 1973<sup>104</sup> it was noted, as a matter arising from the meeting of the English RTDs, that Dr William Maycock<sup>105</sup> 'had produced data on the incidence of Au positive blood among prisoner donors. The evidence was being re-examined and English directors were considering withdrawal of prison sessions'.<sup>106</sup> The minutes do not disclose any further discussion of the matter by the Scottish Directors.
